If possible, the lamp should be so designed that no dash pot or springs are required in its mechanism. This is very important, as many readers have probably experienced more or less trouble from dirty dash pots, feed and cut-out springs. In many cases these lose their tension, which would either keep the lamp out entirely or destroy all adjustment, allowing the lamps to burn 30 to 70 volts instead of 45 to 50. The writer knows of some cut-outs that would not shunt the lamp until the arc reached about 140 volts. This, of course, would burn the shunt coils in the lamp, as they were only designed to stand a maximum of 70 volts. I believe all will agree that the spring and the dash-pot are the most frequent causes of trouble on a high tension street lamp, which is subjected to internal heat and to dust and dampness.

The lamp should be of light weight, say 25 lbs., complete with hood, hanger board and globe, so as to allow the use of lighter construction and suspensions; a light lamp will also make the old balancing weights unnecessary, and on shipments of lamps the freight is about one-half of that paid for old type long and heavy lamps. The lamps should be adapted for either inside or outside service without change; at the same time they should be so designed that if necessary the plain cover can be substituted for a fancy one without any changes on the lamp. The lamp should be as short as possible, say about 24 inches from top of hanger to bottom of globe, so as to allow the lamp to be used in low-studded buildings, basements and hallways. If it should be necessary to have a long lamp in order to suit some particular customer it can be done by simply putting on a longer cover without changing the mechanism of the lamps. The lamp should regulate so that its voltage would not vary over 5 volts at any time from normal.

The lamp that is designed and built so as to come up to the above specifications should certainly meet with the approval of most station managers and electrical engineers. Since the invention and perfection of the enclosed arc lamp it is possible to build a lamp of the type above mentioned, and the writer, after personally handling nearly 100 of them for street lighting purposes during the past ten months, has come to the conclusion that it is the most convenient street lamp and will surely occupy a prominent position among the enclosed arc lamps, as it possesses higher efficiency than any other type of enclosed arc lamp as yet advertised in this country. The light from the high tension enclosed series arc lamp possesses all the advantages that are so noticeable in the low tension d. c. enclosed lamp, which are, a perfectly steady light, perfect diffusion and distribution, the tint of which can be governed by the use of different combinations of globes. It burns from 100 to 150 hours with one 12x½ solid ("imported") carbon. This not only saves labor in trimming and attention, but the lamp mechanism and clutch do not wear, as the lamp feeds only a few times every twelve hours. It must also be remembered that the clutch works on the soft carbon, which prevents it from wearing, and as there are no carbon rods the repairs on an enclosed arc lamp are only about 10 per cent. of that for the open arc system.

If we now get a lamp as per above suggestions it would be perfectly proper to ask the following question, if one does not already realize the economy of a plant equipped with this type of lamp for street lighting: How do these lamps compare with the open arc system in regard to amperes, voltage and candle power? The old type open arc lamp requires 10 amperes and 45 to 50 volts (equal to 450 to 500 watts) to produce what is known as 2,000 nominal candle power. The new enclosed arc lamp with clear globes requires 7 amperes and about 71½ volts (equal to 500 watts) to produce 2,000 nominal candle power. From the above figures it can be seen that the wattage remains the same for both types of lamps; consequently, the coal bill is not increased when one uses the enclosed series lamps. The enclosed arc lamps require about 20 per cent. higher voltage, but the amperage may be reduced accordingly. I consider this a great advantage, especially if the circuits are very long, as the line loss would be cut down considerably. If 1,200 candle power system is desired, the wattage consumption would be about 300 to 325 (equal to 4 amperes and 80 volts, or 5 amperes and from 68 to 70 volts). I mentioned in the early part of the article that a shunt wound high tension series enclosed arc lamp could be so designed that it would operate with the same arc voltage, even though the amperes vary about 40 per cent. The advantage of this will undoubtedly be seen. To-day almost any manufacturer of arc dynamos will furnish regulators and controllers, by the adjustment of which the amperage may be changed from, say 4½ to 6½ amperes, and the dynamos will hold their amperes very steadily at any point. This enables one to get a perfectly controllable arc circuit, which may be varied at will from the station.

On dark nights the dynamo may be run at 7 amperes. The next night may be moonlight, then the dynamo can be cut down to say 5 or 6 amperes; then, during winter, when snow is on the ground, one will not need over say 5½ amperes during the darkest nights. On moonlight nights with snow on the ground one could probably go as low as 4½ amperes on the circuit and still the streets would be equally well lighted as they would be on a very dark night with 7 amperes. This feature of this system will save a station or a town a good many dollars. Figures show the following:

200 lamps at 70 v. each = 14,000 v. $\times$ 7 amp. = 98,000 watts.
200 lamps at 70 v. each = 14,000 v. $\times$ 4½ amp. = 63,000 watts.

This shows a saving of 35,000 watts per hour. If the plant can produce one electrical h. p. per hour with 4 lbs. of coal, one would save during an 11-hour run on 4½ amperes instead of 7 amperes about one ton of coal, equal to say, about $2.00. By applying this system I am sure a great many plants which now shut down at 12 p. m. could persuade the town which they light to pay a little more and run on a very low amperage the rest of the night, and then it might be profitable to run an all-night incandescent circuit. I am sure lighting plants in small towns could get many new customers on their incandescent circuit if they could afford to run until daylight instead of shutting down at 12 p. m. These are only a few examples showing the many advantages that can be gained through the use of this system There are many stations which have 4 to 7 ampere dynamos that are not in use, for, as the town grows, the requirements change, a larger light is wanted and a 10 ampere arc system has to be put in. Now, clean and fix up the old 4 to 7 ampere dynamos and write for prices and information to arc lamp manufacturers who make a high tension series enclosed arc lamp. Be sure that the manufacturers guarantee the lamp to burn on a varying amperage of say, about 3, without change in the voltage at hangers, as the old type dynamo may not regulate as well as

the later designed and improved types. So it is seen, if the town board should vote to put in 15 or 20 new 2,000 c. p. arc lamps, and the present 10 ampere dynamos are loaded, one can, if an old 6½ ampere dynamo is on hand, by simply buying this type of lamp and putting up new circuits, furnish this town with this lamp and save the cost of a new dynamo.

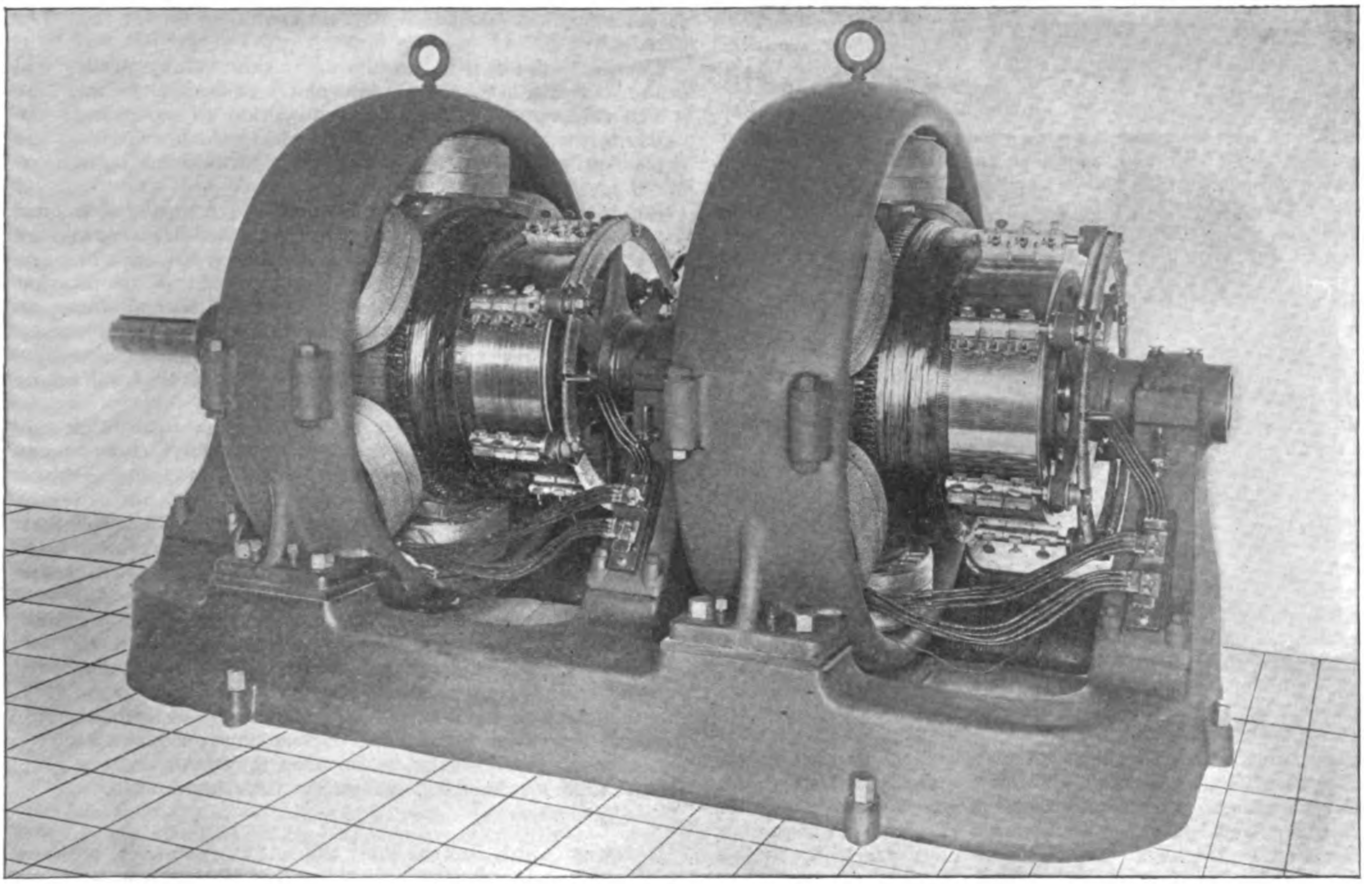
The foregoing explanations and suggestions might alone show station managers how they would profit by the use of an arc lamp of this type, but I will now call your attention to the most important fact, and that is, that this lamp operates for 125 hours without any attention or trimming. At each trimming there is only used one 12x½ ("solid imported") carbon. The cost of this quality of carbon is between $27.00 and $30.00 per 1,000; consequently a lamp of this kind, if operated 10 hours every night in the year, will consume 30 of these carbons per year, equal at highest carbon price to 90 cents. If the carbon for the old type open arc lamp cost $15.00 per 1,000 pair, delivered (this is certainly the lowest cost figure), then a lamp of that type which consumes one pair of carbons each night of 10 hours, requires 365 pair for one year, equal to $5.47½, and making a saving of $4.57½ each year per lamp in carbons alone.

As the enclosed arc only needs trimming once every 10 or 15 days, one or more trimmers may be dispensed with. The enclosed arc having an inner globe, a deduction of about $1.00 per year for each lamp might be made from the above figures to allow for the additional chances of breakage.

Special 220-Volt American-Ball Generator.

THE accompanying half tone represents a special generator of 150 k. w. capacity, just designed and built by the American Engine Company of Bound Brook, N. Y., for the Crookston Water Works at Crookston, Minn., where it will be driven by a turbine shaft through a friction clutch coupling, running at 300 revolutions per minute, and used for supplying direct current to a three-wire system. As will be seen, the generator consists of two dynamos on a single base and having a common shaft, making a very compact combination.

This machine is required to run at a very low temperature, and without any brush movement, and has been designed to meet the most exacting requirements.



150 K. W. 220-VOLT GENERATOR, TWO MACHINES ON A SINGLE BASE, AND HAVING A COMMON SHAFT.

TELEPHONY AND TELEGRAPHY

Telephone Bill Argument at Albany.

AT the second committee hearing on the Brush telephone bill, to regulate and nominally lower rates in New York State, on March 10, at Albany, Mr. U. N. Bethell, general manager of the New York Telephone Company, made a most convincing argument in opposition to the passage of the bill. He showed that it was defective and loosely constructed, and that it was very feebly supported, there being no demand for its passage from any large body of telephone subscribers from whom support might naturally be expected were the measure a proper one. In explanation of this lack of support, Mr. Bethell gave a sketch of the progress of the New York telephone system under message rates, which effectually opened the eyes of the committee to the defectiveness of the Brush bill and to the inexpediency of interfering with the telephone exchange industry as it is now conducted in New York State. At the beginning of 1895 there were 10,396 exchange stations in New York City, practically all at various flat rates. The message rate system had been introduced tentatively in 1894 and at no time had all the subscribers, or nearly all, paid the $240 rate for unlimited service, which is the only price the supporters of such bills as the Brush ever mention. From 1895 to 1898, the New York system under the active development of the message rate scheme had had a remarkable growth. The gain in subscribers from the beginning of the company's existence up to 1895, a period of 16 years, had been 10,396 stations. The gain from 1895 to 1898, a period of three years, had been 11,199 stations, or about 110 per cent. At the end of 1897 there were in New York City, 21,595 exchange stations and a total of 23,865 stations of all classes, exclusive of those in the company's central offices. This marvelous growth continues, for in January and February of the present year there had been a net gain of 1,071 exchange stations. Such an unparalleled increase,

equaled by no other telephone system in the world, could only be accounted for on the supposition that the customers of the telephone service were satisfied with the present charges. Those charges were based on a minimum rate sufficient to meet the fixed expense of the plant and force necessary to render a minimum amount of service, and on a subsequent charge varying with the amount of service used by each station.

Mr. Bethell reviewed in detail the arguments that had been made in favor of the bill, the bill itself, and the history of the New York telephone system. He showed that the principal speakers in favor of the bill, who appeared only to advertise themselves or to justify their existence as officials of busybody associations, while disingenuously declaiming against the $240 rate, as if that were the only price at which telephone service could be had in New York, actually took service themselves at message rates, and being people in a relatively small way of business, only paid about $120 to $130 a year for their service. The bill itself was loosely prepared and had not been amended to meet the objections scored against it at its previous appearances—it had not even been amended to conform to the different conditions arising from the creation of the new city of Greater New York. It was further open to the grave legal objection that in forming a commission of State officers to regulate rates, it imposed judicial functions on executive officials sworn to the performance of entirely different duties in the service of the State. From a practical telephone point of view, the bill attacked the interests both of the telephone companies and of the subscribers. The bill imposed a maximum rate, and a maximum rate meant really a flat rate; for the message rate system meant that users paid according to their use, and consequently it could not be worked in connection with a maximum rate. Some 85 per cent of the New York stations pay an average rate below that imposed by the Brush bill. The Brush bill would enable the company to charge subscribers who make small use of the service more than they now pay, for the benefit of the large users, who would pay less. But what would the result be? No law can compel a man to take for $125 that for which he now pays $90 or $100. Many of the small users would give up the service—which they need, or they wouldn't take it—and the company's business would be thrown into confusion. The bill would therefore be inimical to the interests both of the subscribers and of the company. The figures previously quoted showed that the company was making every legitimate effort to extend its business at rates that were equitable and just, and the doubling of the system in three years was equivalent to a certificate on the part of the public to the correctness of the company's policy.

In dealing with the comparisons with foreign cities, made by those who spoke in favor of the bill, Mr. Bethell pointed out that the figures they quoted were invariably inaccurate, and that they also omitted to mention the much lower charges obtaining in Europe for labor, material, rents, wayleaves, rates and taxes. Also that the service was generally inferior, as all American travelers knew, and that the subscriber was usually constrained to contribute to the capital account in some way or other, either by payment of an installation charge equal to a year's rental, or by providing his own instruments and part of his line, or by paying his rental annually in advance. American companies did not practice such methods, and a detailed comparison would show very different results from those that might be deduced from the loose statements of the supporters of the bill.

A Report Against the Pacific Cable.

A dispatch from Washington states that Representative Corliss, of Michigan, has completed the minority report of the House Committee on Interstate and Foreign Commerce against the bill reported by that committee for the establishment of a Pacific cable. The original bill provides for a subsidy to the Pacific Cable Company at the rate of $100,000 a year for 20 years, and provides for the completion of the cable to Honolulu by 1900, and to Japan and China by 1901. The substitute offered by Mr. Corliss and Mr. Fletcher, of Minnesota, also provides for a subsidy not exceeding $100,000, but it eliminates the name of the corporation, and has a provision for advertisement by the Postmaster General and the co-operation of the Government of Japan. The report indorses the proposition of a cable, but objects to the bill of the majority because it grants an exclusive monopoly, a subsidy of $2,000,000, and holds that all franchises should be open to competition. It also says that another American corporation is ready to enter into a contract to construct the cable. The report continues: "It is well known that Japan stands ready to grant a like or greater subsidy for the construction of this cable, in addition to the subsidy proposed in these measures, and it is believed that for the public good the President should be clothed with power to secure the co-operation of Japan for the construction and maintenance of this important public work, and the minority therefore submit an amendment authorizing such action, with the expectation that such co-operation and competition will result in securing the establishment of a cable at a much less figure than it is proposed to grant to the Pacific Cable Company by the measure submitted by the majority of the committee."

Practical Features of Telephone Work—II.

BY A. E. DOBBS.

STARTING THE NEW EXCHANGE.

In beginning the work, the "new company" will have one advantage, viz., the support of the people, provided they can be convinced that the newcomer means business. Rightly or wrongly there is considerable prejudice against the older company, and most communities would welcome competition; for the old theory that the telephone business is a natural monopoly, has no more foundation in fact than in regard to railroading, telegraphy or electric lighting, and an active solicitor will not only secure many of the old company's subscribers, but will add a host of others who could not be reached at old-time prices. Some business men will, of course, regard two telephones as a nuisance, but their attention must be called to the fact that they can reach about twice the number of subscribers at the same price they formerly paid for one instrument, and that competition insures better service, and to a certain extent a duplicate service, in case of trouble on one or the other lines.

Another point worth considering is this: Many parties will desire to retain both the old and new telephones. In this case it is an advantage and an accommodation to so arrange the numbers that business men in advertising do not have to use two sets of numbers. In other words, give them the same number they already have.

But it will not do to forget that the old company will meet the cut rates; that it has, or will have, first-class equipment, and men who know how to handle it; that it has, or will have, first-class instruments and long-distance connections—this latter being a very distinct advantage, until the new toll lines can be built—and while people may put up with indifferent service for two or three years, for the sake of having competition, the one giving the lowest rates and the best service will finally secure the bulk of the business.

Scattered throughout the country are many towns that will support exchanges of from 50 to 500 subscribers, and it is to these we will first turn our attention; it is exchanges of this size that are most in need of advice, as larger ones generally make it a point to secure fairly good engineering talent. First secure a superintendent, or foreman, who understands his business and give him entire support as long as he is worthy, and be sure that he is broad-minded enough to employ good men to do the work. Line and exchange work is an art that cannot be learned in a week. I know of one exchange that had a very costly experience. Owing to the narrow-minded jealousy of the superintendent, the work was done by green men; so much so that it became pretty well understood that a good lineman could not hold a position there. The owners however found him out and let him go eventually, since when they have spent a great deal of money rebuilding, that might have been saved.

WIRE.

In towns of this size the lines will not average over, perhaps, ¾ of a mile in length, and well galvanized steel or iron wire will answer every purpose. In New York and the New England States, wire the size of No. 12 B. W. G. should be used—though many companies use No. 14. In States not visited by severe storms, No. 14 answers every purpose.

If I remember rightly, the old Western Union test of galvanized wire was to plunge the end into strong muriatic acid four times, withdraw it quickly, and wipe it off each time. If blackened after the fourth plunge it was not considered satisfactory, but if the zinc coating still remained bright, the wire

was passed. This test, however, is a severe one, and was probably adopted because the W. U. wires generally follow railroad lines, where smoke and steam are hard on them. Good, ordinary No. 14 steel wire will stand three plunges, but not always the fourth. If it will not stand three plunges, do not buy it at any price.

Wire bought from firms who make and advertise telephone wires, will generally stand this test. Still, as it only takes five cents' worth of muriatic acid to make this trial, the buyer does not have to take anybody's word as to the quality.

Now, in advising the use of iron wire for grounded, or common return lines, we will, no doubt, run counter to some of our young friends who will ask: "Is not copper a better conductor than iron?" "Does it not possess less self-induction?" "Will it not last longer?" "If it is the best, why not use the best?"

Stop a minute, and let us do a little thinking. Iron or steel wire, sizes No. 14 and No. 12, B. W. G., can be bought at from $3 to $6 per mile, while No. 12 B. & S. copper, which is certainly small enough, will cost about $15; quite an item in a bill for several hundred miles. Then while iron wire requires only 33 poles to the mile, copper will need about 40; another little item worth considering. Iron again, does not require such care in handling, so that the men can make better time putting it up. It is true that its self-induction is greater than that of copper, but with the apparatus in common use the difference cannot be distinguished up to five or six miles. It is well known that induction coils of 250 ohms are made to transmit clearly over from 2,000 to 4,000 ohms of line resistance, and it requires no great mathematical ability to discover that 50 or 100 ohms difference in resistance will make no difference in the volume of sound perceptible to the average ear. Then again in a common return system, the resistance of the iron wire is an advantage in allowing a smaller return wire to be used.

Iron wire wears out; so does copper. To be sure, copper can be sold for junk, and it is also true that it is frequently stolen. Iron wire will last five or six years and can be renewed at any time; besides, conditions will change; for it often happens that pole lines, expected to carry only a few wires, become loaded down, and vice versa. Then, at the end of five or six years, when most of the wires and some of the poles need renewal, the managers will have had experience enough to deal with conditions as they then exist.

Since the use of iron wire does not necessitate poor work, is a great deal cheaper, and since except for very long lines it is practically just as good, why not use it? There is a time when cheap line material will answer every purpose; as there are conditions that require the best of everything. Therefore save money on wire and high priced insulators, and put it into some other part of the plant.

Of course there are systems that require copper wire and metallic circuits in exchange work, but these are special systems, and they require special treatment. Sometimes, however, it is deemed advantageous to call the attention of the public to the fact that iron wire has been discarded. Even in that case three or four dollars a mile can be saved, by using the Roeblings' bi-metallic wire. Theoretically it seems better than either copper or iron alone, for grounded, or common return systems. Though it has only about 67 per cent. of the conductivity of copper, the manufacturers claim that for grounded circuits it gives as good results as copper, section for section, which may be due to the fact that alternating currents of high periodicity travel on the surface, and do not penetrate deeply into the metal at their first impulse, and it is possible that the self-induction and resistance of the steel core confines the current more largely to the surface, preventing what is called the skin effect, in retarding transmission. It stands the weather as well as hard drawn copper, and the steel core gives added strength, therefore requiring fewer poles. There are local telephone companies using a considerable quantity of it.

ALUMINUM CONDUCTORS.

I learn that for electrical conductors the Pittsburg Reduction Co. are prepared to put aluminum wire on the market at a price that will make it cheaper than copper, section for section. It is very light, a mile of No. 12 B. & S. weighing only 32 pounds. It will stand the elements as well as copper, and has the same freedom from self and earth induction, and as a conductor is far superior to iron and has about 63 per cent. of the conductivity of pure copper. These are points at least worth considering.

MECHANICAL

The Gas Composimeter.

THE gas composimeter is a new instrument, which, as the name implies, measures the composition of gases. It automatically and continuously samples, indicates and autographically records the per cent. of the desired constituent, thus producing a continuous and true record of such constituent, as it occurs at any moment in the gas mixture sampled.

The principle employed is applicable to the determination of any absorbable constituent of a gas mixture; but the form herein illustrated is especially designed for the continuous determination of carbon dioxide, or carbonic acid gas.

Every combustible constituent of fuel requires a definite amount of oxygen for complete combustion, and produces a definite quantity of heat. This heat is absorbed by the products of combustion and the surrounding objects. Carbon constitutes from 50 per cent. to 95 per cent. of all industrial fuels, whether

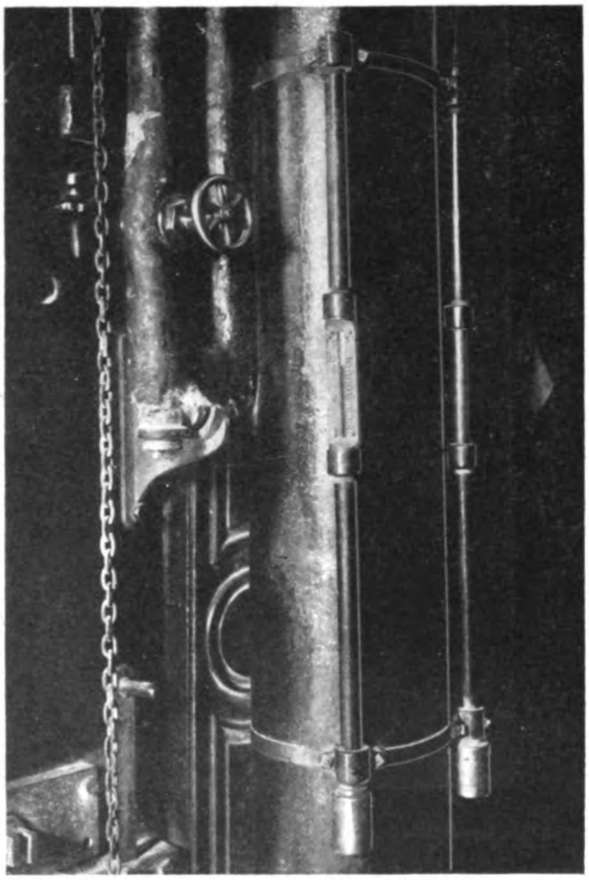


FIG. 2.—COMPOSIMETER INDEX FASTENED TO COLUMN IN FRONT OF A BOILER.

solid, liquid or gaseous. Combustion consists in the act of chemically combining the fuel elements with the oxygen of the air. The natural effect and general object of combustion is heat. Confining ourselves to the principal fuel element, carbon, we have the fact that it has two stages of combustion. In the first stage one atom of carbon combines with one atom of oxygen and forms one molecule of (CO) carbon monoxide. This molecule of CO unites with another atom of oxygen forming (CO_2), carbon dioxide, completing the combustion of the carbon.

Atmospheric air which consists of 23 per cent. of oxygen and 77 per cent. of nitrogen, a small per cent. of carbon dioxide and a variable quantity of moisture, furnishes the oxygen for all ordinary combustion. In the first stage of combustion one pound of carbon combines with 1⅓ pounds of oxygen and forms 2⅓ pounds of carbon monoxide gas, mixed with 4½ pounds of nitrogen, producing 4,400 heat units, which quantity of heat is

capable of evaporating 4½ pounds of water from and at 212 degrees.

The carbon monoxide thus formed is capable of uniting with another equivalent of oxygen, and for each pound of carbon an additional 4½ pounds of nitrogen are brought in with the required oxygen from the air, forming 3⅔ pounds of carbon dioxide mixed with 9 pounds of nitrogen, producing 10,100 heat units capable of evaporating 10½ pounds of water from and at 212 degrees. Complete combustion of one pound of carbon therefore requires in round numbers 12 pounds of air, resulting in 13 pounds of products of combustion, producing 14,500 heat units which is theoretically capable of evaporating 15 pounds of water into steam from and at 212 degrees.

It is thus evident that it is of the utmost importance that sufficient air must be furnished to provide the oxygen necessary for complete combustion. On the other hand it is no less important that an undue excess of air be avoided. In the one case fuel in the form of carbon monoxide is permitted to pass out at the stack, in the other the heat generated by combustion is absorbed by the excess of air and is carried out at the chimney, reducing the useful effect of the fuel. If the exact amount of air could be given to burn carbon completely the products of combustion would contain 21 per cent. of carbon dioxide, and the greatest possible efficiency would be attained. In practice this perfection cannot be realized and to avoid the loss by the formation of carbon monoxide, an excess of air is always given. Since the quantity of air required to furnish the oxygen necessary to completely burn one pound of carbon is always the same, it is evident that the percentage of carbon dioxide must decrease as the excess of air increases.

Every cubic foot of air not required for combustion that passes through or over the fire carries with it its quota of heat, which is wasted up the chimney. The excess should therefore be regulated to a minimum. A well stocked and regulated fire should form no appreciable amount of carbon monoxide with an excess of 30 per cent. of air. This amount would give 16 per cent. of carbon dioxide in the products of combustion and yield 93 per cent. of the efficiency that complete combustion without an excess of air would give. Under these conditions, allowing the gases to pass up the chimney at 525 degs., there is an unavoidable loss of 7 per cent.

An excess of 60 per cent. of air gives 13 per cent. of carbon dioxide and means a loss of 13 per cent., of which 6 per cent. is avoidable. An excess of 100 per cent. gives nearly 10½ per cent. of carbon dioxide and means a loss of 20 per cent., of which 13 per cent. is avoidable. An excess of 150 per cent. of air gives 8¼ per cent. of carbon dioxide and means a loss of 31 per cent., of which 24 per cent. is avoidable. An excess of 200 per cent. gives only 7 per cent. of carbon dioxide in the products of combustion, which means a loss of 40 per cent. up the chimney, of which 33 per cent. can be saved, on the basis underlying all these calculations, which is, that 30 per cent. of excess of air is sufficient and that the stack temperature is 525 degs.

Complete combustion of the carbon can be attained with considerably less than 30 per cent. excess of air, and a greater excess does not insure the absence of CO in the products of combustion. An uneven fire will produce CO in any case, and the products of combustion will show low in CO_2 at the same time. The percentage of CO_2 is therefore the best measure of the economical condition of the fire.

Fig. 1 illustrates an equipment of a system of sixteen instruments for measuring carbonic acid, as installed in a large boiler house and in full operation. To the right are the composimeters, and to the left the recording gauges, one for each boiler in a battery of sixteen.

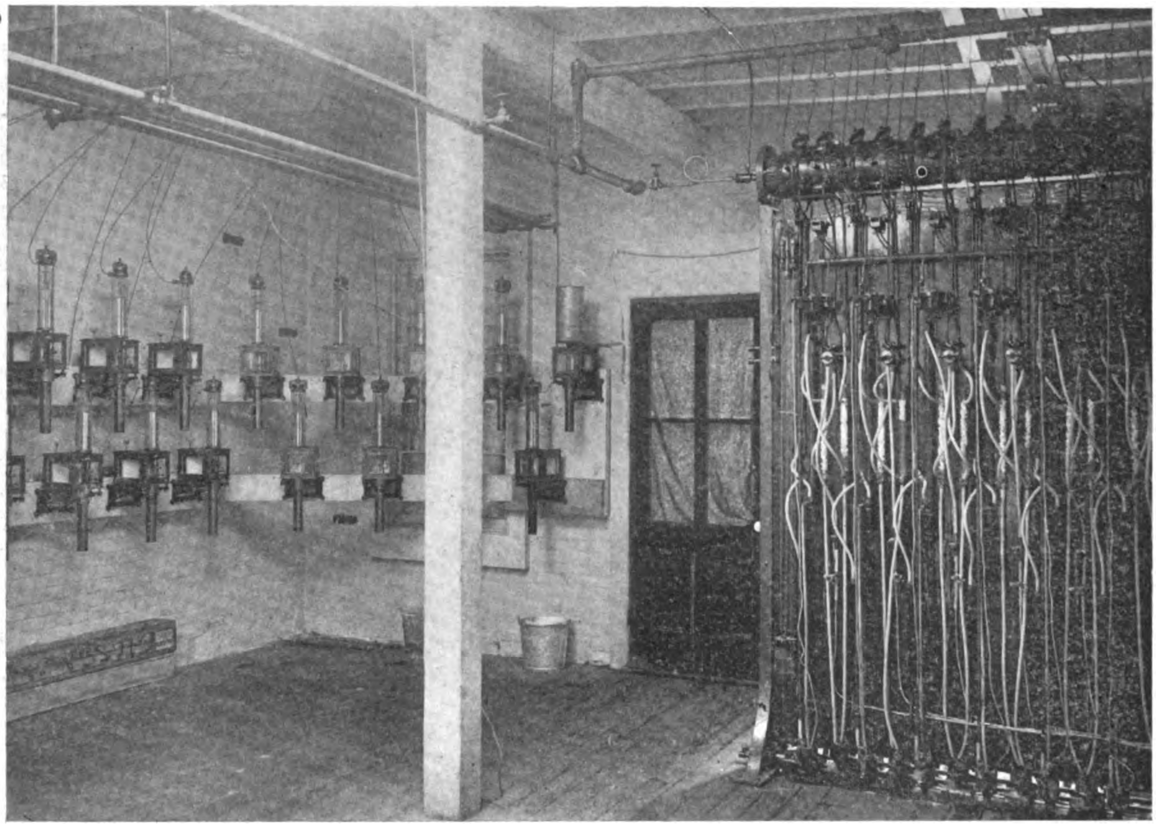

FIG. 1.—EQUIPMENT OF SIXTEEN COMPOSIMETERS AND RECORDING GAUGES IN A LARGE BOILER HOUSE.

Fig. 2 shows the index fastened to a column in front of the boilers, in plain view of the fireman, showing him at all times the condition of his fire, and enabling him to regulate his fuel bed and draughts, so as to attain maximum efficiency.

Figs. 3 and 4 are fac simile of autographic records (scale ½ size) made by the gas composimeter and also of the pneumatic pyrometer. Fig. 3 shows three 8-hour records. A is from an ordinary return flue boiler, running under light loads and natural draught. B is from a sectional safety boiler working under full load with natural draught. C is from a return flue boiler, driven to the fullest capacity with an air pressure ⅜ of an inch of water under the grate. Omitting the noon hour in A and the intervals for cleaning fires, A shows an average percentage of CO_2 not over 9 per cent.; B shows fully 10 per cent., and C 15 per cent. of CO_2.

Under these conditions of combustion, allowing a stack temperature of 525 degrees and assuming that carbon is the fuel and

that no appreciable amount of carbon monoxide passes off with the products of combustion, record A indicates a loss of 27 per cent.; record B a loss of 22 per cent.; record C of only 8 per cent. due to excess of air, all within the range of possibility to avoid. The products of combustion producing record C contained less than half of 1 per cent. of CO.

B B, Fig. 4, is a reproduction of B, Fig. 3. A A is an autographic temperature record, showing the heat of the furnace about 6 inches below the boiler, and directly over the grate. The sudden drops in the temperature are caused by the cold air rushing in when the fire door was opened for the purpose of coaling up or cleaning fires, which operations are perfectly recorded, both as to the time and duration. The cold air rushing in not only reduces the temperature in the furnace, but at the same time dilutes the products of combustion and hence the per cent. of CO_2 to be correct must drop with the temperature. The perfect accordance of the records which were simultaneously taken is proof of the correctness and fidelity of both.

The value of such an instrument will be highly appreciated by engineers and superintendents of works who have been laboring with the ordinary analytical methods to determine the CO_2 in chimney gases, for the purpose of controlling the fireman with a view to economizing fuel. By the aid of this instrument the economical condition of the fire is continually before the eyes of the fireman. When the indication of the carbonic gas falls below the economical per cent. it means that the fire is getting too thin and must be replenished, or that it has holes through it and must be attended to.

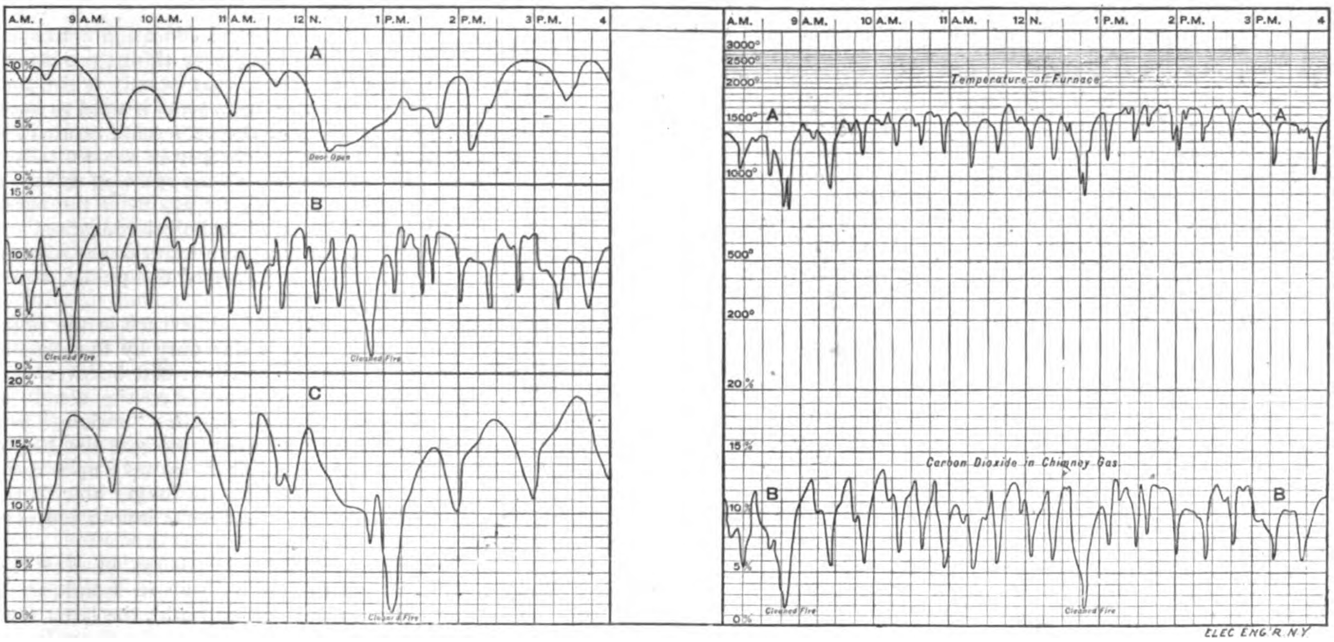
From the autographic record the engineer or superintendent can always see how well the fireman attended to his duty all through his turn, as well as at any particular hour or minute. It shows how often he fired, how long the doors were ajar, when the fires were cleaned, and what time was consumed in cleaning. It furnishes unbiased data by which to compare the work of different firemen, and results of one day's work with another. Different methods of firing can be tested without trouble and the best method adopted.

Few people have any idea of how much fuel is wasted up the chimney because of inefficient and careless firing. There is probably not one boiler plant in a hundred in which at least 5 per cent. of the fuel could not be saved by the intelligent use of the gas composimeter, and there are many plants where from 15 to 20 per cent. could be saved on the coal bills.

The gas composimeter is especially valuable in connection with plants equipped with mechanical stokers and forced draught or blast. The percentage of carbon dioxide in the products of combustion being continuously in sight, the stoking apparatus can always be regulated to the point of best economy.

The gas composimeter as illustrated may be placed in any suitable position within 100 feet from the boiler to which it is attached.

Further details and information on this interesting apparatus may be obtained from Messrs. Uehling, Steinbart & Company, 61 Mulberry street, Newark, N. J., who manufacture both the gas composimeter and the pyrometer.



FIGS. 8 AND 4.—FAC SIMILE OF AUTOGRAPHIC RECORDS (SCALE ½ SIZE) MADE BY THE GAS COMPOSIMETER AND PNEUMATIC PYROMETER.

EDUCATIONAL

Technical Education.

A VERY able address on the above subject, of which the following is an extract, was delivered by Prof. W. E. Ayrton, F. R. S., to the students of the Coventry Technical Institute, the occasion being that of the distribution of prizes. He said: The object of technical instruction is to enable a person to apply himself with advantage to some industrial pursuit. Such instruction may now be obtained at very many technical schools throughout the country, and in a much less formal way a large amount of technical information can, of course, be picked up in a factory by an intelligent person.

The ideal technical school would be one attached to the works, in which the employé would be systematically taught their trade, the application of the principles of science to their particular industry, and so forth, in somewhat the same sort of way that in former times the few apprentices were taught the "mysteries of their craft" by their master. But modern development has not tended in that direction, and at the present time, instead of a manufacturer deputing his teaching duties to persons paid directly by himself to perform them on his behalf, he delegates them to the nation generally. And the nation, recognizing the fact that the apprenticeship system is dead, accepts the responsibility, passes Technical Instruction Acts, and builds technical schools in which people can learn at a small fee how to use their brains and their hands for the benefit of themselves, for the benefit of the masters, and for the benefit of the nation at large.

Not only have technical schools come into existence in consequence of the universality of the division of labor in our day, but they are maintained to counteract the evils that arise from this very division of labor; and the remedy they apply is to give the apprentice a far wider knowledge of his trade than he can obtain from the highly specialized work at which he is kept in the factory. And so it is hoped that should the workman have his particular division of the trade taken away from him by the

general introduction of some machine, he may be able to avoid loss of work by turning to some other branch more or less allied to his own.

Great hitherto has been the diversity of opinion as to what should be taught at a technical school. Some advocate that the teaching in chemistry, for example, should be limited to a sound training in chemical principles and methods, while others urge that a technical school should be expected to teach the actual application of science to industrial processes. A third party, on the other hand, consider it proved that a technical school may with advantage aim at imparting a knowledge of what a few years ago would have been slightingly called mere handicraft.

Personally, I see no objection to instruction in any use of the hand being given at a technical school provided that it be accompanied with teaching that leads the worker to use his brain also; or, perhaps, I should say that since the teaching of any use of the hand cannot be adequately given without its being accompanied with a certain amount of mental training, such teaching has a perfect right to be regarded as a part of technical education. I am aware that a sharp distinction between education and training has been drawn by some authorities, and that they have pronounced it a misnomer to apply the name education to what is often called the training of the hand and eye. This appears to me, however, to be a mistake, for there is no radical difference in the method of trial and error which has to be followed in learning to perform any useful operation really well, whether it be making a first-rate fit between two pieces of material, skilfully fingering the violin, or adroitly solving problems in Euclid. Determination, application, the appreciation of the importance of accuracy and continued practice are necessary in each case, and the bodily as well as the mental improvement which is effected in the individual during the acquisition of any such form of dexterity is of the nature of education, but does not by itself, of course, constitute an entire education. When the dexterity has been once acquired, however, the mere repeated use of it is neither education nor training, any more than the daily solution of problems in trigonometry would be an education after a lad had mastered the methods.

So far from there being a risk of the instruction in a technical school becoming too practical, there is a much greater risk of its becoming too purely theoretical. For when a technical teacher has to spend the greater part of his time giving out information, he has but little left to take any in, and he thereby runs the risk of losing touch with his trade, or profession, especially if it be one in a state of rapid development, like electrical engineering. His so-called practical teaching may then easily become unpractical and untechnical, academic, stereotyped, and only distantly related to industry.

I would urge on my teaching brethren that not only should we keep in close touch with the trades we represent, not only should our aim be to avoid imparting antiquated, or unpractical, knowledge, but we should make an effort to keep our teaching to some extent even in advance of the industry it deals with.

There is, however, one subject of overwhelming importance which it is incumbent on every technical school to teach, especially as it is one that has been much neglected in the past, and that is the knowledge that the wide employment of machinery in a country is a real gain to every one of its inhabitants. Whether one reads in Charlotte Brontë's "Shirley" what was the feeling concerning the use of machinery at the beginning of the century, or in to-day's newspapers what is the attitude of certain workmen towards machinery now at the end of the century, one is struck at finding the same stubborn resistance fostered by the some misguided notion that the amount of work to be done in the world is a fixed quantity, and, therefore, that it ought to be dealt with sparingly and parcelled out like food among a shipwrecked crew, so as to be made to go as far as possible.

Speaking about the benefits to be derived from machinery, Prof. Ayrton said: Which, for example, is the country where the earnings of the workmen are the largest? Why, the United States—the one in which the use of machinery is the most extensive, where the highest wage goes with the smallest bill for labor in employments like the manufacture of steel, which, although developed in this country, is, partly for this reason, being rapidly wrested from us by America. The American preference for doing purely mechanical work with inanimate machinery, and reserving the animate instrument—man—for brain work, combined with the wide diffusion of technical knowledge on the other side of the Atlantic, has already inaugurated a keen rivalry with Great Britain. And this rivalry—which extends not only to foreign markets, where perhaps we could only hope to be on an equal footing, but even in the supply of goods to our own colonies and dependencies, where we might have expected to have an advantage—will grow into a supremacy unless we keep on our guard, and give unmistakable evidence of our readiness to adapt ourselves to new methods of manufacture.

But I hear some of you saying, this is political economy, or, at any rate, the economics of industry and not technical education, and that it would be unsuitable to offer such considerations to students who come here to learn watchmaking, weaving and woodworking.

Well, a good deal of sound political economy may be taught in connection with watchmaking. It might, for example, be impressed on the student that while the idea of using machinery in watchmaking was started in England, it was in America that it was first carried into practice, and it was Americans who first made large fortunes with machine-made watches. Meanwhile, the English watch industry steadily declined, until your townsman, Rotherham, revived it by introducing American watchmaking machinery in the face of the opposition of his workpeople, the loss of money, and apparently great loss of time. Now Mr. Rotherham employs automatic machines, constructed in his own engineering shop, with which he can turn out 500 high class watches per week, and so his name is known in many other places besides Coventry.

A most important part of all technical education consists not merely in encouraging people to learn how things are done today, but in leading them to ascertain what exactly is the particular result each special manufacturing process is used to accomplish, and then to consider whether the very same result cannot be arrived at more simply and more cheaply in some totally different way. For analysis and synthesis—the splitting up into elementary components and the building up again—is the basis of much invention, as it should be of all technical education.

It will be seen that one of the most important duties of a manufacturer is to create wants on the part of the public, and not merely to supply existing demands.

But there seems to be a considerable difference in the importance attached to the performance of this duty by the American and the English manufacturer. The American believes in the proverb, "L'Appétit vient en mangeant"—appetite comes with eating—and so he manufactures and supplies "notions" before the public is aware it is in need of them, whereas the Englishman, with some brilliant exceptions, does not take up a novelty until it ceases to be one, and until he is no longer able to resist the clamour of a public hungering after some innovation of recognized utility.

Contrast, for example, the overhead railways in New York and Chicago with the underground railway in London. The first were always airy (I have traveled on both), the latter always sulphurous, as I know to my cost. Yet, while the steam locomotive on the overhead American lines has given way to the electric motor, the use of electric traction on the London underground system—which is really a far more pressing necessity—is even now only under consideration.

The substitution of electric for horse traction in streets, which has excited so much interest in the world generally during the past few years, and which is just beginning to attract general attention even in our own country, differs from the bicycle trade and the electric light industry in that while giving work to many it must at first interfere with the employment of some, such, for example, as stablemen, dealers in horse fodder, harness-makers, etc. Ultimately, however, the total number of people who will be employed in connection with tramways will certainly be largely increased by the application of technical knowledge in the development of electric traction, for at the present time there are over 17,000 miles of electric tram lines in the streets of the United States on which run some 50,000 tram cars propelled with electric motors. Indeed, in Boston, which has a population only about one-tenth of that of London, the steam engines in the various stations which drive the dynamo machines for supplying electric current to the tramways can develop nearly 50,000 horse power continuously if required, and this, bear in mind, is altogether apart from, and in addition to, the engines driving dynamos for the electric lighting of that city.

The moral then seems to be for the methods taught at a technical school to be kept well up-to-date, and for you, its students, to do your best to excel in them, ever striving the while to increase your stock of those all-important characteristics—alert-

ness, thoroughness and truthfulness—not merely truthfulness in word, but also in work at the bench, the forge, and the vice, the truthfulness which is the slayer of shoddyism.

LETTERS TO THE EDITOR

The Review of Mr. Wiener's Book.

HAVING read Mr. Wiener's recent book, also Mr. Thorburn Reid's virulent review of the same in The Electrical Engineer of March 3, I feel that as a matter of common justice, both to Mr. Wiener and his publishers, and to the public, the latter should not be allowed to go unchallenged; for this excellent advertisement "next to pure reading matter" Mr. Reid has offered to the public "with an assumption of authority likely to give to those not conversant with the subject the idea that he is master of it," urged on by a sense of duty which would not allow him to forego an opportunity to glorify himself at the expense of the reputation of both Mr. Wiener and his book, and in a style suggestive of a country editor referring to an "esteemed contemporary."

Taking up these strictures in their order, the writer believes that they are poorly grounded and come from a hasty, if not malicious, inspection of the book.

Very few titles are comprehensive, and Mr. Reid can hardly expect one to form a compendious synopsis of the contents. Referring to page 34, first paragraph, the writer would like to have Mr. Reid explain how the diameter of an armature, whether smooth or toothed, can be increased without increasing the area of the air gap, the polar arc remaining constant, or without increasing the circumference.

While the method may be empirical, the writer believes that it is also practical, being based upon results obtained in actual practice, and if the tables are not correct, Mr. Reid cannot expect his allegations to that effect to stand without being more specific and offering proof.

As to the table on page 52, the writer believes that "the best modern practice" in this regard is purely a matter of conforming with required conditions of speed and output per unit of weight, it being the practice of the company with which the writer is connected to build machines of any size to run at any required speed. Attention is also called to the fact that this table is qualified by the paragraph preceding it.

A superficial inspection of table 6 and the paragraph preceding it (which Mr. Reid refers to further on) at once gives the impression that Mr. Reid's criticism is justifiable, and it is only by a thorough perusal of the book that this subject matter becomes understood, for we then find that this matter applies to intensity per square inch of air gap and is based on considerations of magnetic leakage.

The law stated in the fourth paragraph on the first page of chapter 3 is, without question, correct, for from a consideration of the fundamental law at the top of the same page, it is evident that a foot of inductor moving at the rate of one foot per second will cross one square foot per second, or 144 square inches, and as it is assumed that there is one line of force per square inch, this gives 144 lines, and there will be generated 144x11-8 volts, which is in no way a contradiction of the well-known fact that the cutting of a given number of lines generates a certain voltage, irrespective of the length of conductor, but in this case the length of conductor is given to simply serve as one factor to determine the number of lines of force.

Page 35, second paragraph, refers to an expedient with which Mr. Reid is, apparently, unfamiliar; for, given an armature supplied with a commutator with twice as many bars as there are coils in armature, and half the bars would be dead, while by cross connecting them to active bars, and supplying additional brushes, the effective brush surface will be the same as would be obtained by doubling the length of the commutator.

As to the effect that commutation has upon the magneto-motive force, it is very slight in any case, and as to the statement at the bottom of page 30, a study of Ewing's magnetization curves show that when iron has responded to an increase of magneto-motive force, a reduction of this force to its original value is not followed by a corresponding response by the iron, owing to the residual magnetism, or the "magnetic memory" of the material.

If the work in question is so replete with errors and erroneous statements as claimed by Mr. Reid, it is unfortunate that his random selections did not chance upon those which would bear a closer scrutiny. H. R. WELLMAN.

North Tonawanda, N. Y., March 16, 1898.

The Blumenberg "Carbon-Consuming Cell."

IN the description of the Blumenberg carbon-consuming cell, appearing in The Electrical Engineer of March 3, the claim is made that superheated steam supplies indirectly, by the alternate formation and decomposition of metallic oxides, the oxygen which combines with the carbon to form either carbon monoxide or carbon dioxide.

I wish to call attention to the fact that the oxidation of carbon to either the monoxide or the dioxide by such a process could not evolve energy, no matter what metallic oxides may be employed or whether they are entirely or only partly reduced during the process. Whatever metallic oxide may be employed as the transforming agent, the total energy resulting from the two reactions of decomposing water and subsequently oxidizing carbon would be the same as though the carbon acted directly on the steam. On the assumption that CO_2 is formed the sum of the reactions would be

$$C + 2H_2O = CO_2 + 4H.$$

Assuming that the water is introduced in the form of steam, the reaction would absorb over 20,000 calories, equivalent to a counter-electromotive force opposing the reaction of 0.21 volt.

On the assumption that CO is formed, instead of CO_2, the sum of the reactions would be

$$C + H_2O = CO + 2H.$$

This reaction would absorb 30,000 calories, equivalent to a counter-electromotive force of 0.64 volt.

If any electrical energy is evolved from a cell having the above reactions as the final result, it must be derived from the heat of the furnace, that is, it must be thermo-electric. But such reactions would not be possible under the conditions stated without the simultaneous formation of hydrocarbons, which Mr. Blumenberg does not mention. What becomes of the hydrogen left from the decomposition of the water? It cannot escape without carrying with it at least enough carbon to form CH_4, unless he claims to liberate free hydrogen. The energy lost in the escape of hydrocarbons will bear looking into.

The statement that natural ores could be used as "oxygen-bearing compounds" to develop electrical energy from carbon and simultaneously reduce the metal from the ore can apply only to the oxides of copper, as that is the only common metal whose oxide exists in nature as an "ore," which carbon has sufficient energy to reduce without absorbing external energy. The statement would apply to the oxides of mercury and a number of rare metals, such as thallium, silver, gold, platinum, palladium and iridium, but these oxides have not yet been found in nature as ores. CHARLES J. REED.

Philadelphia, Pa.

Traction Competition in Sweden.

Mr. R. W. Pope, Secretary of the American Institute of Electrical Engineers, received a communication the other day from the Vice Consul of Sweden and Norway at Washington, saying that the Royal Administration of the Swedish State Railways invites civil engineers or other interested parties to a competition of designs for the arrangement of new railroad stations, junctions, etc., etc., for the city of Stockholm. The first prize is to be 12,000 Swedish crowns (about $3,230); the second, 8,000 Swedish crowns (about $2,150), and the third, 4,000 Swedish crowns (about $1,075). The time for competition will expire at noon on the 31st of August, 1898. Particulars concerning the nature of the work will be furnished by the Swedish-Norwegian Legation, 2011 Q street, Washington, D. C., or by the Vice Consul of Sweden and Norway, Mr. August Peterson, Le Droit Building, corner F and Eighth streets, Washington, D. C. Security to the amount of $13.50 for the use of the drawings in this competition is required, but this will be refunded when the drawings are returned.

Vol. XXV. NEW YORK, MARCH 24, 1898. No. 516.

The Inauguration of The Electrical Engineer Institute of Correspondence Instruction—Broadening the Bases of Electrical Education.

IN all times and in all ages it is learning and education which have distinguished man from his fellow man more than any other attribute. The things that make for education have therefore, with few exceptions, been fostered by the liberality of States or by private individuals, with results that have added immeasurably to the happiness and wealth of the world. What perhaps most distinguishes ancient and medieval educational efforts from those of modern times is the fact that the former were from the very nature of the conditions then existing confined to a small minority of the population, whereas to-day education is "popular" and is carried to its farthest limit.

Taking our own country, for example, its large number of universities, colleges and schools, both State and private, furnish admirable facilities for the acquisition of an education in all branches of the sciences and arts, and are accomplishing notable results, attested beyond doubt by the enormous development of knowledge and industry throughout the United States. Yet, notwithstanding the existence of so many educational institutions, the fact remains that many thousands, even hundreds of thousands of men and women, who desire more light, are by circumstances of one kind or another debarred from availing themselves of such institutions. That this condition of affairs is recognized and that attempts have been made to meet it, is evidenced by the so-called "university extensions." These auxiliary schools are doing admirable work and their influence is constantly aiding the diffusion of knowledge. But their scope is, perforce, limited, especially in the technical branches, and the methods of imparting knowledge pursued are not adapted to serve the wants of the great bulk of the population lacking the preliminary training necessary. How to meet the demand of the masses and more particularly of the toilers in the workshop and factory who want to lift themselves to higher spheres of usefulness than those of mere tenders of machines, has become one of the social problems of the day. Debarred from the advantages of an education which the technical schools afford, many a worker in the shop has hitherto sought in vain for a substitute. This is particularly true of the rank and file in the electrical arts which have sprung up like magic in the past twenty years. Moreover, besides the workers at the lathe and bench or engine, there are many occupying responsible positions as foremen, overseers and superintendents whose previous training took no account of the then unfamiliar electric arts, but who to-day see themselves confronted on every hand by the applications of electricity to the various industries with which they are connected. Then, again, the majority of experienced engineers, if of more than ten years' standing, graduates of schools of mechanical, mining, civil, hydraulic and other technical branches, often feel their impotency in dealing with the electrical questions constantly forced upon them; and they have striven to find a way out of the difficulties besetting them from their lack of information.

That this condition of affairs exists we know well from the letters received by the hundred from persons in every walk of life—from the workman, engine driver and dynamo tender to the practicing engineer. Our chief resource in the past has been to refer these anxious and earnest inquirers to the books best suited to their requirements. Of books on electrical subjects, there is no lack, it is true, but for the purposes of the classes of readers above referred to, books, as a rule, contain either too much or too little—much that is too advanced for the untrained student and mechanic, and too little for the engineer trained in other branches. What constitutes the greatest drawback to a book in the hands of the unassisted beginner is, that it answers no questions. Besides, even the newest electrical book is rarely up to date. The pressing nature of many of the communications above referred to has for a long time past impressed upon us the desirability of devising some plan by which the exact requirements of each individual could be met. It became evident from the start that a plan of this nature must possess two indispensable features. In the first place, it must involve but a small expense to the student; and in the second place, the system of instruction must permit of the student asking as many questions and receiving as many answers thereto as he may require to make clear every point as he goes along. While investigating methods best adapted for carrying out these ideas, the Toussaint-Langenscheidt system of language teaching now in extensive vogue abroad suggested itself; and it is based upon this system that The Electrical Engineer has established as an entirely separate and distinct enterprise The Electrical Engineer Institute of Correspondence Instruction. The aims of this Institute are to enable any one desirous of obtaining a thorough knowledge of the electric and allied arts to acquire it through the instrumentality of carefully prepared, printed lessons, supplemented by a system of confidential correspondence carried on between the student and the Institute, in which the student is at liberty to ask as many questions as he likes until he is satisfied that he thoroughly grasps every point in the lesson he is studying.

The advantages of such a system must be obvious. It constitutes each student a class by himself, leaving him entirely unhampered, as he would not be in a class of students, by dull or quicker associates; while on the other hand it guards against his being hurried through a course to keep up with a scheduled term. Each student can thus take his own time, and this permits him to study at such periods as he finds most convenient in the daily routine. Only he and his teacher need know that he is studying.

Without entering more deeply in the plan adopted, which is set forth elsewhere in this issue and is detailed in a pamphlet, to be had on application, we believe that The Electrical Engineer Institute of Correspondence Instruction will help solve the problem of affording to those desiring it the means of obtaining an adequate practical education in any of the branches of applied electricity. It goes without saying that The Electrical Engineer Institute of Correspondence Instruction is not in any sense intended to be a competitor with, or a substitute for, the estab-

lished schools of electrical engineering. Our advice to those whose time and income permit of it, is to attend such schools by all means. The Correspondence Institute, however, is the next best thing which we can recommend for the seeker after electrical knowledge. If the man cannot go to the university, the university can come to him.

In launching this new enterprise, we are fully alive to the responsibilities involved, and have made every proper arrangement to deal with them. We desire here to state that the Institute is a distinct corporation, operating under our auspices, its good faith and trustworthiness guaranteed by the standing of this journal. It is under separate management, has separate offices, and will be carried on without any relation whatever to the work and policy of The Electrical Engineer as a technical publication. We are deeply interested in its success, and shall do all we can personally to promote its welfare, believing that this is but one more way of raising the standard of electrical work and of advancing the electrical arts in the development of which we have long taken an active share.

A word as to the management of the Institute of Correspondence Instruction. The direction has been placed in charge of Mr. Herman A. Strauss, E. E. This gentleman has had a thorough electrical and mechanical training, acquired in this country and abroad, and brings also to his work a practical experience in teaching which cannot fail to inure to the greatest benefit of those who may entrust their electrical education to the Correspondence Institute.

A Matter of Station History.

IT has been said that the authoritative history of great national events cannot be written less than a hundred years after their occurrence, that is, after all the evidence is in. The historian who attempts to record and to discuss causes and consequences immediately after the event, be he ever so conscientious, may lack some sources of information and thus unwittingly leave himself open to criticism. What is true of national affairs is equally applicable to those that mark the progress of an art, and the electric arts in particular have been prolific in instances in which a revision of statement has been called for. It is hardly to be expected that the journalist in his record of contemporaneous progress can have access to all the data. In fact, part of his usefulness lies in eliciting it by controversy. It is thus that we find ourselves at the present time, with some correspondence before us from two very well-known men, each with claims to prior consideration. The "apple of discord" appears to have been a remark contained in the article descriptive of the new work of the Brooklyn Edison Company, in our issue of January 6. That article stated that "the credit of pioneering this movement in actual practice is due to the Brooklyn Edison Illuminating Company." Our readers will recall that the movement referred to was the adoption, in Brooklyn, of the high tension three-phase current for transmission and its conversion for every required purpose for local distribution, including direct three-wire, alternating and series arc lighting. The claimant to priority for this system is Mr. L. A. Ferguson, electrical engineer of the Chicago Edison Company, for whom it is contended that the suggestion of the use of this system of transmission and distribution was originally made by him to Mr. Barstow of the Brooklyn Edison Company as early as the spring of 1896; also that in a report to his company dated February 15, 1896, he advocated the adoption of such a system for the Chicago Edison Company, which ordered the apparatus in May, 1896. Mr. Ferguson also furnishes data as to the fact that he was the first to suggest to the engineering department of the General Electric Company, at Schenectady, the methods leading up to the development of this class of apparatus for use in connection with the Edison three-wire system. Additional testimony to like effect is cited in the remarks made by Mr. W. L. R. Emmet of the General Electric Company in a paper read before the National Electric Light Association in May, 1896. Mr. Emmet, however, withheld the name of the company (the Chicago Edison Company) that contemplated installing the system referred to.

In reply to the exceptions taken, Mr. Barstow of the Brooklyn Edison Company concedes that the idea of generating two kinds of current, direct and alternating, from the same generator, using the direct current for the immediate system and the alternating for transmission through rotary transformers to outlying territory, is due to Mr. Ferguson. Mr. Barstow points out, however, that when he entered upon the work of reorganizing the Brooklyn Edison Company's system in 1895 he found that in Europe there existed a multiphase system using rotary transformers, and with this as a preliminary starting point he began to work out the present Brooklyn system. But while such a system was easily applicable to the Edison low tension business, as in the case of Chicago, there had been, so far as he knew, no transforming devices developed whereby the multiphase system could be transformed into high tension continuous current for series arc lighting, except rectifiers, or whereby it could be transformed into alternating current of different phase and frequency. Without entering into greater detail, we may state that Mr. Barstow holds to the correctness of the statement appearing in The Engineer of January 6 that the Brooklyn Edison Company was the first to use in practice a three-phase system of transmission which is converted into any desired system of distribution, such as Edison 115 direct current, 500-volt railway current, 6,000-volt continuous current for series work, and two-phase 60-cycle current for local distribution. The fact that the production of alternating and direct current from one generator proposed by Mr. Ferguson, and employed in Chicago, is not in use in Brooklyn, Mr. Barstow believes, ought to relieve him from the responsibility of appropriating to himself the credit due Mr. Ferguson for that system.

With this evidence before them we leave it to our readers to form their own judgment on this rather interesting friendly controversy.

The Haines Vacuum Tube Lighting System.

THE New York World, in its issue of Sunday, March 20, describes the methods employed by Mr. John H. J. Haines in the production of light by means of vacuum tubes. Mr. Haines produces high frequency currents by means of a coil and double spark gap. It is claimed that with the wattmeter showing 200 watts energy consumption in the circuit, 16 tubes 5½ feet long and 2½ inches in diameter were lighted to full brilliancy. Mr. Haines is quoted as stating that he could equip an ordinary three-story house with his system for $200. This would give four tubes to each room, the power coming from the street circuit.

SAVED BY TELEPHONE.—A well known gentleman in this city, received last week a letter from his son, addressed to his daughter-in-law, in which the writer said he was in Washington in great suffering, and intended to take poison. Friends in Washington were immediately called up over the long distance telephone, and the young man was found by them at his hotel writhing in the agonies of poisoning. He was soon put in the hands of doctors, and his life was saved.

KLONDIKE. The electrically operated cable road over the Chilkoot Pass, driven by Westinghouse motors, is reported open, with a capacity of handling 150 tons of freight daily.

MISCELLANEOUS

Magnet Winding Curves.

BY J. P. STONE.

BY the use of the accompanying curves the calculation of the space required for the winding on magnet spools is greatly facilitated. These curves apply not only to magnet spools, but to any spools that are wound with wire. The diameter of wire can be easily found from the following formula:

$$\sqrt{\frac{A.\ T. \times L.}{V}}$$

This will give the diameter of bare wire in mils (or thousands of an inch). When A. T. = ampere turns per spool, L = mean length of one turn in inches, V = volts across one spool.

The number of turns and size of wire being known, the space required for the winding is found by dividing the total number of turns by the number of turns per square inch, as taken from the curves, for either single, double, or triple covered magnet wire.

In winding coils, unless the wire is put on in absolutely even layers with an equal number of turns per layer (which is possible only when using large wire and taking great care in winding), after a few layers are put on, the wire will be found to be somewhat uneven, and it becomes necessary to put in a strip of paper to even it up. The difficulty in winding wire accurately increases rapidly in small sizes, and this gives rise to waste space.

In calculating these curves, allowances have been made for imperfect winding (varying with the different sizes of wire), that have been found to give good practical results. There is a slight difference in the thickness of insulation used by different wire manufacturers, but this is not sufficient to lead to any trouble. The curves were figured for an average of all the principal makes.

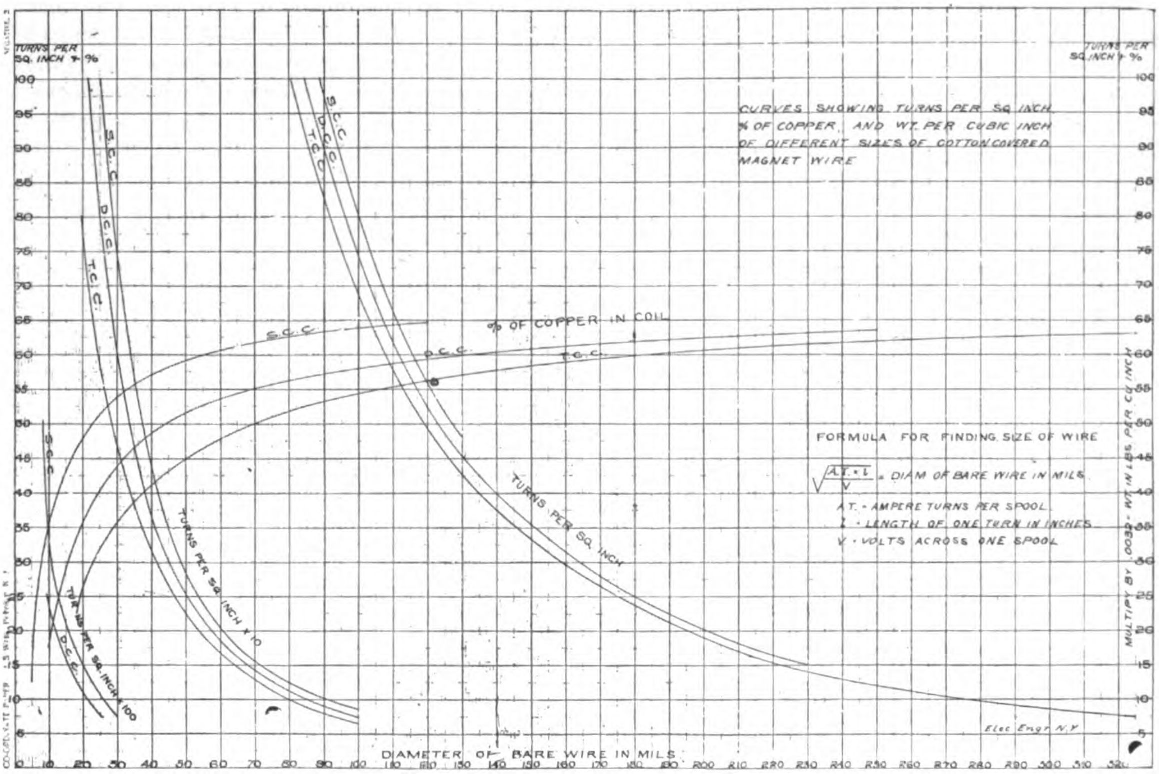
In order to plot the curves on a reasonable sized sheet the curves showing turns per square inch have been repeated twice, and the turns per square inch taken from the column on the edge of the diagram should be multiplied by 10 and 100 respectively.

Curves are also given showing the percentage of copper, that is, the percentage of copper in the total space occupied by the wire. The weight of wire can be found by multiplying the per cent. of copper taken from the curves by .0032. This will give the weight in pounds per cubic inch, the number of cubic inches being the area of the winding space on spool, multiplied by the mean length of turn.

Single covered wire larger than No. 8 or No. 10, B. & S. gauge, or about .120 inches diameter, is seldom used, and larger than No. 3 and No. 4, B. & S. gauge, or about .2 inches diameter, is usually triple covered, as this heavy wire is very stiff, and in winding it the insulation is easily broken.

Triple covered wire is not used in small wire, as the insulation is less likely to get damaged in winding, and also on small wire the insulation takes up such a large percentage of the total space occupied, that it is uneconomical to use a heavily insulated wire, unless occasion requires, this is easily seen by glancing at the curves of percentage of copper.

Hence, triple covered wire smaller than No. 22, B. & S. gauge, .025 inches diameter, and below No. 30, B. & S., or, .01 inch diameter, double covered wire is seldom used, as for these small sizes single cotton covered wire is generally sufficient. On small wire silk is used as a covering, as it occupies less space, but for most work cotton covered wire is preferred on account of its smaller cost.



CURVES SHOWING TURNS PER SQUARE INCH, PER CENT. OF COPPER, AND WEIGHT PER CUBIC INCH OF DIFFERENT SIZES OF COTTON-COVERED MAGNET WIRE.

Annual Report of the U. S. Patent Office.

The annual report of the Commissioner of Patents for the calendar year 1897 has been laid before Congress. It shows that in 1897 there were received 45,661 applications. Patents granted amounted to 23,729. The number of patents that expired was 12,926. The total expenditure was $1,122,843; the receipts over expenditure were $252,798.

In proportion to population more patents were issued to citizens of Connecticut than to those of any other State—one to every 786 inhabitants. Next in order are Massachusetts, District of Columbia, New Jersey, Rhode Island and New York. To residents of England 706 patents were issued; to residents of Germany, 551; Canada, 286; and France, 222.

The number of applications received for examination in the

year was greater than for any other in the history of the office, yet the report says there was no increase in the facilities of force for doing the work. Applications awaiting action on December 28 last numbered 11,382, due to the inadequacy of the office force.

Since 1882, 155 examiners and assistant examiners have resigned voluntarily from the office. The places left vacant by these men cannot be filled at once, and their resignation is a serious loss to the Government. An increase in salaries would hold a fair proportion of them.

A New Standard of Self-Induction.

A standard of self-induction, which can be theoretically computed with extreme accuracy has been constructed by I. Fröhlich. He cut a ring of Carrara, marble into a rectangular section, and wound it with a single spiral layer of insulated copper wire of radius 0.11147 mm. in 2,738 turns. The marble ring was 35 cm. broad and 20 cm. thick, and weighed over 100 kilogrammes. Its magnetic moment was, however, only 0.45. The advantage of using a single layer of fine wire was that no error was introduced by pressure of outer layers, and the correction for thickness of wire was only one-thousandth of the total coefficient, the latter being approximately 0.1 by 10^9 cm.—(Fröhlich, Wied. Ann., No. 13, 1897.)

The Preparation of Copper Samples for Conductivity Tests.

BY DR. S. SHELDON, Polytechnic Inst., Brooklyn.

WHILE the electrical fraternity is interested with the subject of standardization of electrical apparatus I should like to call atention to the necessity of adopting a standard condition of softness for samples of copper whose conductivity is to be tested. Of coures, users of copper wire are interested in the conductivity of the wire in the condition in which it is furnished to them—not in the conductivity which might have been given to the wire, if it had been treated differently. While the copper losses in most electrical machinery are but a small percentage of the output, and while the temperature at which the machinery will operate is uncertain, owing to the uncertainty of the factors entering into the heat escape, still in many cases a reduction of the copper losses by a few per cent. is worth struggling after. The determination of the conductivity of wire used for such purposes is an easy matter. On the other hand the requirement of a definite conductivity, frequently found in specifications for construction work, where rubber covered or similar wire is to be employed, gives no opportunity for the verification of the fact that the requirements of the specifications have been complied with. It is impossible to determine the cross section of the wire and the value given by the manufacturer must be accepted. Again the tinning of the wire makes the resistance measurement valueless. These difficulties are met in some cases by the purchasers sending inspectors to the factories to determine the conductivity before the wire is covered. This is perhaps the best solution of the problem under the circumstances and, according to Abbott, is the practice in American aerial line construction. To electrolytic copper refiners and all buyers and sellers of bulk copper for electrical purposes, a standard method of treatment of test samples is of utmost importance. Cases have been known where copper, contracted for future delivery at a certain price, has been rejected at the time of delivery because of too low a conductivity, the ruling price at the time of delivery being less than at the time of making the contract.

The American Institute of Electrical Engineers has adopted as its standard of conductivity for copper the value given by Matthiessen for soft copper. This is contrary to the original advice of the Committee on a Standard Wiring Table and resulted from statements made in the discussion of the report that there were many degrees of hardness, implying that a soft condition was easily obtainable and could be reproduced. To ascertain whether this were true or not I had two students of last year's class at the Institute, Messrs. Alfred Muller and Herman Wallatt, investigate the influence of softness upon the conductivity. A sample of wire was passed several times through holes in a draw-plate in such a manner as to yield a very hard wire. This wire was cut up into separate lengths. The assumption was made that the resistivities of these lengths were equal. The lengths were then separately subjected to different annealing temperatures for a fixed interval of time, the sample, in one set of experiments, being placed in a vacuum, and, in another set, in hydrogen. The different temperatures were produced by sending different currents through the samples. The temperatures were calculated from current measurements and measurements of voltage between separate potential terminals on the samples, Kennelly's temperature co-efficient being assumed as correct. After treatment the conductivities of the samples were calculated from measurements of resistance, length, weight and specific gravity. The results obtained for samples annealed in a vacuum are given in the following table:

Number of Sample.	Annealing Temperature.	% Conductivity.
1	20°	101.5
2	37°	101.5
3	54°	101.5
4	118°	101.6
5	215°	102.0
6	300°	102.1
7	600°	102.4
8	755°	102.7
9	930°	99.0

The results for samples which were annealed in hydrogen are given in the following table:

Number of Sample.	Annealing Temperature.	% Conductivity.
10	20°	99.0
11	45°	99.0
12	105°	99.3
13	234°	99.8
14	360°	101.0
15	483°	101.9
16	1050°	89.3

One end of sample 16 melted after annealing current had been flowing for about a minute. A sufficiently long wire remained for the conductivity test. This sample was very soft and had lost much of its tensile strength.

These results show that annealing to a softness which shall give a maximum conductivity must take place at a high temperature regulated within rather narrow limits. The maximum mechanical softness would be obtained if the sample were melted and, after being cast in a graphite mould, were allowed to cool off slowly. Very smooth filiform samples can be obtained in this manner. But the conductivity of copper is so dependent on the amount of suboxide of copper which is present in it, and this amount is altered to such an extent by melting, that the conductivity determinations on such samples give no indications of the electrical properties of the original samples. As has been recently stated by Swan, the electrical conductivity of electrolytic copper is reduced by more than one per cent. by melting and casting into the form of wire bars. It would, therefore, appear to be better to subject all samples to the hard drawing process. Conductivity tests would then properly indicate the original electrical quality of the copper.

Municipal Electric Lighting.[1]—V.

BY PROF. JOHN R. COMMONS.

THE city of Watervliet has, for seven years, furnished its 115 arc lamps at a cost of $75 each, including depreciation, but not interest. Its neighbor, Troy, has paid a private company $146 for like service. Watervliet's plant cost $26,000, but was paid for in two assessments without the issue of bonds. Distributed over the entire period, this investment would have been equivalent to $31 per lamp year, making the total expense to the taxpayers $106, against the $146 paid by Troy. It is proper enough that interest should be omitted from the computation of Watervliet's annual expense, and, should a commercial system be added, the consumers should have the benefit of charges based on freedom from interest payments. Therefore, while criticizing Professor Parsons' reasons, I agree that both he and city officials are right in figuring interest only on the outstanding debt. This gives the true cost of production to the taxpayers, and the saving of interest in this way must be counted as one of the most important economies which municipal ownership brings. This saving, of course, does not appear

[1] Municipal Affairs, Dec., 1897. A Reply to R. R. Bowker. See Elec. Engr.

prominently in the early years of the enterprise, but it becomes increasingly valuable as fast as the debt is liquidated. Foster's computation of interest at six per cent. on the entire cost of plant to date is therefore doubly excessive, for, besides the falsely high rate, it includes interest on new construction paid out of profits and savings which are not properly considered an investment and entitled to interest payments.

EFFECT OF MUNICIPAL OWNERSHIP ON RATE OF TAXATION.

The amount of taxes paid by electric light companies varies so widely in different States and cities that it is impossible to state a rule that will have general application. Parsons says that the amount actually paid by the companies is about two dollars per arc equivalent or three-fourths of one per cent. to one per cent. on the fair investment. In New York City, according to the census report, it was one-third of one per cent. on the total valuation, or, omitting patents, six-tenths of one per cent. In the State at large it was one-half of one per cent.

According to the report of the Massachusetts Gas and Electric Light Commissioners the total amount of taxes paid by all the electric light companies of the State for the year ending June 30, 1896, was $168,218.83, which was four per cent. of their gross receipts ($4,187,260), six and two-tenths per cent. of their operating expenses ($2,739,783), and 1.06 per cent. of their total assets ($15,892,336). The two Boston companies with the equivalent of 22,970 arc lamps of 2,000 capacity each, installed for both street and commercial lighting and motors, paid in 1896 taxes amounting to $72,333.96, being $4.42 per arc equivalent, and 1.05 per cent. on the combined assets of the companies ($6,898,786).

The Edison Illuminating Company of New York, with the equivalent of 42,582 arcs, installed in 1895, paid for "general and legal expenses and taxes," $218,421, equal to $5.13 per arc, showing taxes to be much less than in Boston.

The Detroit assessors at the request of the Public Lighting Commission placed an assessed valuation on the city plant at $427,500, the amount of the investment for the year having been $714,843.76. Computing city taxes on this valuation, the loss to the city in taxes was $7,981.43, or $5.10 per arc light, or one and one-tenth per cent. on the cash investment.

The Massachusetts rate of taxation on corporations is unquestionably higher than that in any other State, and the rate of one per cent. on the total investment may, therefore, be taken as the maximum taxes which the city loses through municipal ownership. But it is a mistake to consider this as a loss to the taxpayers. It is more than compensated by the increased valuations of property which follow upon increased municipal lighting. In Jamestown the extension of lamps to the suburbs, and to unimproved property, has contributed largely to the building up of outlying areas and the consequent increase of assessed valuation. Where there is a commercial plant the reduction of twenty-five to fifty per cent. in commercial rates increases the profits of business and hence the valuation of real estate and business holdings. This tends to lessen the tax rate. Altogether, we are justified in omitting the item of lost taxes entirely as an element in the cost of municipal lighting, but for the sake of the broadest possible treatment of the subject I have estimated it in the computations made in this article at one per cent. on the total cost of the plant to date. Were it omitted, it would reduce the cost per lamp per year as herein computed from $2.00 to $5.00 each.

SHOULD MUNICIPAL PLANTS BE INSURED?

Insurance actually paid is usually entered in operating expenses and need not be added as a fixed charge. It is a small item, one-half of one per cent. in Batavia, nothing in Dunkirk, one per cent. in Watervliet, two-tenths of one per cent. in Jamestown, computed upon the total cost of the plant. The larger cities, Detroit and Chicago, do not carry insurance. This is proper enough for a large city where the loss by fire when spread over the tax rolls would cause but an insignificant increase in taxes, but small towns like Tipton, Iowa, whose plant was destroyed by fire, are unable to rebuild, especially if already in debt. In addition to carrying a small insurance, such towns should provide a sinking fund and depreciation fund which are in a way a sort of insurance.

RATE OF DEPRECIATION OF ELECTRIC PLANTS.

Depreciation is the item of keenest dispute in the contest over municipal electric lighting. Mr. Francisco quotes electrical engineers who assert that the depreciation on engines and boilers is 5 per cent., on electrical apparatus lamps and dynamos 10 per cent. He does not itemize any other parts of a plant, and taking these two the depreciation for the first year on the total cost of the Detroit plant would be 1.4 per cent. as follows, instead of 8 per cent. as usually estimated by him.

TABLE VI.

ESTIMATED DEPRECIATION ON DETROIT MUNICIPAL PLANT 1895-6.

	Cost	Rate per cent. of Depreciation	Amount of Depreciation
Steam plant	$82,152	5	$4,107
Arc lamps	29,628	10	2,962
Electric plant	40,842	10	4,084
Balance of entire plant	477,519	0	0
Net cost of plant to date	$630,141	1.4	$9,153

Professor Parsons arrives at his estimate of 3 per cent. depreciation in the following way, taking the Braintree plant as an example.

TABLE VII.

BRAINTREE-DISTRIBUTION OF INVESTMENT AND DEPRECIATION.

	Investment	Per cent. of Depreciation	Amount of Depreciation
Land	$940	0	$ 0
Buildings	6,630	1	66
Steam plant	11,900	4	476
Electric plant	7,640	3	229
Lines	13,580	1	136
Poles	3,630	10	363
Lamps	4,630	4	185
Meters	1,560	2	31
Transformers	2,280	3	68
Tools and furniture	580	8	46
Supplies	610	0	0
Services of architect and engineer	620	0	0
Total	$54,600	2.9	$1,600

For an underground plant like that of Chicago, he figures the depreciation at one and six-tenths per cent. of the total investment, as follows:

TABLE VIII.

CHICAGO-DISTRIBUTION OF INVESTMENT AND DEPRECIATION.

	Investment	Per cent. of Depreciation	Amount of Depreciation
Land	$100,000	0	$ 0
Buildings	66,987	1	669
Steam plant	95,518	4	3,820
Electric plant	58,075	3	1,742
Lines	317,040	1	3,170
Poles	....	..	....
Lamps	41,240	4	1,650
Tools and furniture	610	8	50
Supplies	8,840	0	0
Total	$688,310	1.6	$11,101

Water Power Transmission for Rochester, N. Y.

A BILL has been introduced in the New York State Legislature providing for the incorporation of the Genesee Power Company with a capital stock of $3,000,000, with power to increase to $12,000,000 in shares of $100. The men mentioned as incorporators and directors are: William A. Boland, of New York; Cassius M. Wicker, of the banking firm of Hollins & Company, representatives of the Baring Brothers, New York; Theodore W. Myers, banker, formerly controller of New York City; George H. Keller, capitalist, New York; George W. Rafter, engineer, Rochester.

This company proposes to revive the Genesee River storage dam project in a new form. Heretofore it has been advocated as a State work, but now private capital is about to take hold of and develop the scheme. It is understood that the water right owners and millers of Rochester are a unit in support of the bill, which provides for the building of a dam in the upper Genesee

River, near Portage, and the consequent sale of water and water power.

At a point about 1,400 feet above the Erie Railway bridge the Portage gorge presents very favorable conditions for the erection of a dam. Solid rock exists immediately in the bed of the river, with only a couple of feet of water flowing over it, and also extends high up on the bluffs on either side. Furthermore, the channel is much narrower than the most favorable location hitherto surveyed in the Mt. Morris Canyon, so much so that the actual amount of masonry required to construct a dam 118 feet in height is less than one-half the quantity required for a dam 130 feet in height as formerly proposed at Mt. Morris. This is so because the required depth of foundation is different and to the less length of dam. A dam 118 feet high at Portage would store 15,000,000,000 cubic feet of water as against a mean storage at Mt. Morris of 7,370,000,000. The width of the surface of the lake thus created would be from one to two miles, the widest point being at Rush Creek, in Allegheny County, where there is low land on each side of the river. This sheet of water would be as large as Canandaigua Lake, and have an average depth of 60 feet.

The cost of building the dam, as estimated, is as follows: Land damages for reservoir, $650,000; changing location of the Western New York & Pennsylvania road, $550,000; dam, $1,000,000; wagon road bridges over reservoir, $100,000; clearing reservoir, $30,000; wagon road around reservoir, $30,000; moving cemeteries, $15,000; contingencies, engineering and law expenses, $225,000.

One of the important points made in the bill providing for the incorporation of the company is that it requires the company to hold in store during each navigation season, subject to the requisition of the State Superintendent of Public Works, 2,500,000,000 cubic feet of water, the price per million feet to be subject to arrangement between the Superintendent of Public Works and the company. The company announces that it does not consider that furnishing water to the State will form any material part of its business, but it expects to materially increase the amount of power obtained from the river. One year when it was very dry the river for several months furnished only 5,500 horse power, while with a storage dam the minimum would be not less than 30,000 horse power.

It is also thought that very material sanitary results would be accomplished, not only by keeping clear the bed of the river from Main street to the upper falls, but also by increasing the flow of the lower river, now badly polluted by sewage.

Diagram for Determining the Power of Waterfalls.

MR. OLIN H. LANDRETH, of the Union College Engineering School, in a communication to "Engineering News," gives the following useful information regarding the determination of the power of waterfalls: I send you enclosed a copy of a diagram for the graphical determination of the horse power of any given waterfall, being a simple form for the graphical reading off of the horse power from the formula,

H. P. = H. Q. D. E. ÷ 500, in which:

H = The effective head on the wheel in feet.

Q = The quantity of water flowing in cubic feet per second.

D = Weight of water per cubic foot.

E = The percentage of efficiency of the wheel.

For D = 62.4 pounds per cubic foot; H. P. = 0.1134 H. Q. E.

The inclined lines radiating from the zero at the lower left corner are of three different kinds: Those running to the upper edge of the diagram represent the quantity of water; those running to the right side of the diagram represent the different percentages of efficiency, except the one line which crosses the margin between 85 per cent. and 90 per cent., which is a conversion line to transform the resulting value of the horse power into such linear values as to permit them to be represented by the graduations along the base of the diagram. This line is drawn at an angle with the vertical lines, whose tangent t = ½ (0.1134) 75.v/h, where v and h are the numerical values of the vertical scale of head and the horizontal scale of quantity; the ½ being introduced in this case to make the horse power units along the base of the diagram one-half the value of the quantity units along the top edge of the diagram. To use the diagram: Start with the value of the head on the left margin, pass horizontally to the radiating line representing the given quantity, thence pass vertically down to the proper efficiency line, thence pass horizontally to the inclined conversion line, thence vertically down to the horse power line along the base of the diagram, where the proper value may be read off. With heads or quantities in excess of the maximum value of the diagram, the scales may be assumed changed to ten times that graduated and the resulting horse power read off to a scale either ten or one hundred times

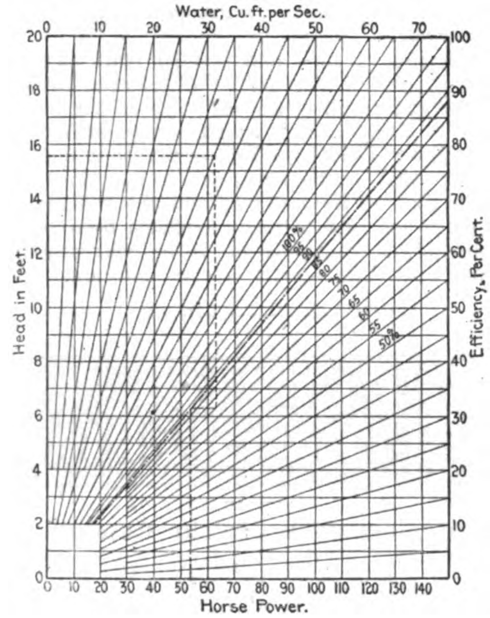


DIAGRAM FOR DETERMINING HORSE POWER OF WATER WHEELS AND WATERFALLS.

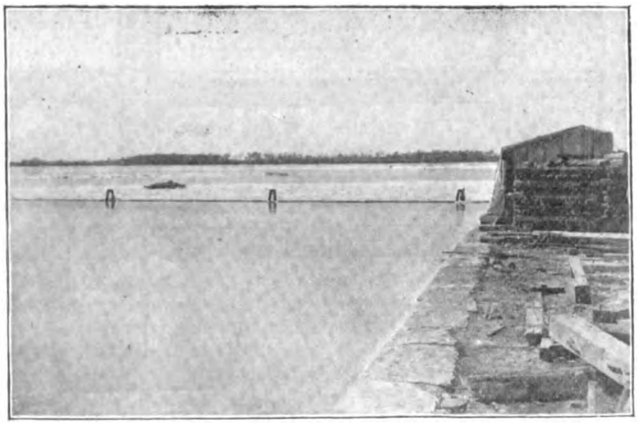
Example: Head = 15.6 feet. Quantity = 40 cubic feet per sec. Efficiency = 75%. Then horse power = 53.2.

that graduated, according to whether one or both the argument scales have been amplified. One or two other arrangements of the lines indicating respectively the heads, quantity and efficiency have been used but the one here given is offered where compactness is the prime requisite.

Preventing Ice and Drift From Entering the Niagara Canals.

WHEN the great ice fields break up in Lake Erie large quantities of it enter the Niagara River at Buffalo and pass down stream to the Falls. In order to prevent it or any other drift entering the canals both the Niagara Falls Power Company and the Niagara Falls Hydraulic Power and Manufacturing Company place booms at the entrance to their canals to protect them. In the case of the Niagara Falls Power Company



METHOD EMPLOYED AT NIAGARA FOR PREVENTING THE ICE FROM ENTERING THE CANALS.

pany the inlet canal is directed down stream at the river and the boom, which remains in place the year around, rests against iron piers firmly fastened to the rock bottom. It serves to effectively divert the ice in winter as well as large quantities of pulp wood which in summer is floated down stream inside a boom from Schlosser Dock to the Niagara Falls Paper Com-

pany's mill. The boom which protects the inlet canal is made of large timbers.

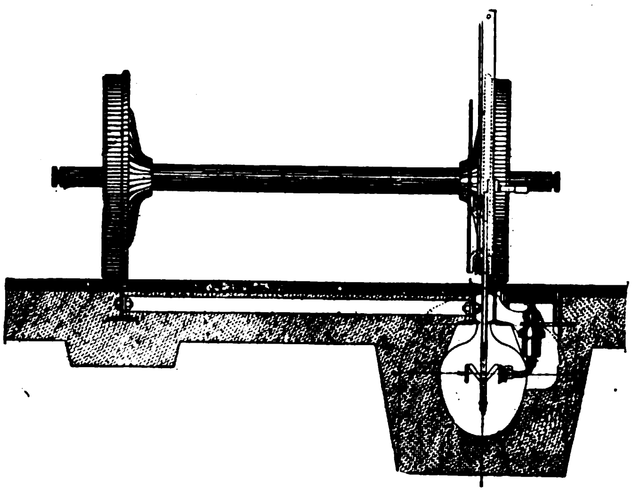
The Niagara Falls Hydraulic Power and Manufacturing Company do not leave their boom across the entrance to the canal the year around, but in summer fasten it to the canal wall close by. With the coming of winter it is placed in position across the entrance to the canal and proves a barrier to the ice entering the waterway.

It is interesting to note that just 50 years ago on the 29th of this month (March 29, 1848) the Niagara River is said to have run dry as a result of a great ice blockade at the entrance to the river at Buffalo. It is stated that so heavy was the field of ice coming out of old Lake Erie at that time that it gorged to such an extent that no water was able to pass down stream, thus allowing the Falls of Niagara to practically run dry. Never before nor since has such a weird spectacle been presented, and the Niagara power companies are to be congratulated that the flow of water to their wheels is ever constant.

ELECTRIC TRANSPORTATION

Improved Siemens & Halske Conduit Railway.

THE underground electric railway system of Siemens & Halske, which has been in use for many years at Budapest and on several short lines in Berlin, is a slotted conduit system, the conduit and conductors being located directly under one of the rails, as shown in the figure. Its latest form is shown in the accompanying cut, which makes an interesting comparison with the recent methods adopted in New York City. The line of one of the rails is identical with the opening of the conduit, and in this way there are only two channels in the street, similar to any ordinary track construction. The one rail is of the ordinary grooved type, laid on a bed of cement or gravel. The other rail rests on the top of the conduit and consists of two similar rails of special cross-section, which leave between them a slot of about 1¼ inches in width. The outer one of these two rails serves as a running rail for the wheel, the inner one as a guide rail. The slot takes care of the rim of the wheel. The double rail rests at convenient distances on cast-iron blocks. This gives the necessary elasticity to the upper construction and insures easy riding. The rails are secured to the blocks by



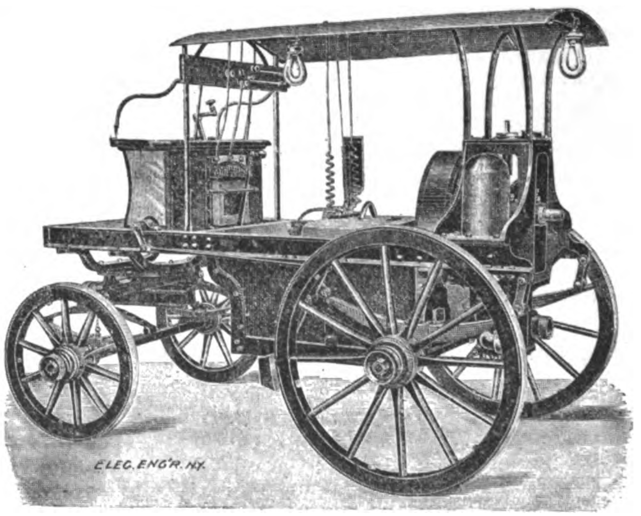
SIEMENS & HALSKE UNDERGROUND ELECTRIC RAILWAY; SECTION THROUGH CONDUIT.

means of angle irons, which are bolted to the foot of the rail. A narrowing of the slot is prevented by the foot of the rail resting against a cast extension on the block. The blocks which span the egg-shaped conduit with two arms serve as ribs of the canal, which is formed of cement built on a wooden foundation. The water entering the conduit through the slot is led into the sewer pipes through numerous outlets provided with means for keeping back all solid matter which might obstruct the passages. The T shaped conductor rails are located along the two sides of the conduit on heavy insulators in such a manner that they cannot be seen or touched from the top, and at such height above the bottom of the conduit that they are not touched by water in the conduits. The insulators are reached through cast iron boxes on the surface, so that they can be replaced with ease and rapidity.

The plow, which is of familiar form, consists of a highly insulated plate, which carries at its lower end two metallic tongues, and at its upper end connectors for connecting it with the motor circuits. The two metal tongues press firmly against the conductors in the conduit by means of springs, and in that way complete the circuit. When it is desired to take the plow out, these tongues close up and do not hinder the operation. In changing over from the underground to the overhead system a special device is brought into action, which cuts the plow in and out of circuit and connects the motor to the trolley without any appreciable loss of time.

A German Electrically Equipped Fire Engine.

THE fire engine illustrated herewith has just been placed on the market by the firm Carl Metz, of Heidelberg, Germany. The machine cannot on account of the weight of accumulators carry its own current generators or source of supply. However, a small battery of sufficient capacity to furnish power for conveying the engine to the place of fire could be carried; but this would make the engine heavy, complicated and expensive. The electric current is supplied from the outside. A modern plant should have its leads running through all the



METZ ELECTRICALLY EQUIPPED FIRE ENGINE.

principal streets and have outlets every few hundred yards. The current can then be delivered to the motor by means of flexible cables carried on the engine. The proper terminals and connecting posts are provided at the cable and outlets. It is proposed to adopt this system in the larger cities and attach the outlet boxes to the sides of buildings. The advantages of the electric motor are the simplicity of service and absolute safety, as long as a low tension current is used. The apparatus will probably be hailed with delight by factories having electrical plants where the fire engine might prove of good and efficient service.

Prizes Awarded by the "Académie des Sciences.'

Among the prizes awarded by the Académie des Sciences for the year 1897 are the following: The La Caze prize (physics) to Dr. Lenard for his work in connection with cathode rays, the Gaston Planté prize to M. André Blondel for his well-known research work in various directions, the La Caze prize (physiology) to Prof. Röntgen for his great discovery, and the Montyon prize (medicine and surgery) to MM. Rémy and Contremoulin, and MM. Marie and Ribaut for collections of X-ray photographs.

LITERATURE

THE PRINCIPLES OF ALTERNATE CURRENT WORKING. By Alfred Hay, B. Sc. London, 1898. Biggs & Co. 276 and iv. pp. 5 x 7 inches. Cloth. Price, $2.

The contents of this book embody the lectures delivered before a class of engineers, and hence the work throughout is kept down to a plane such that it is specially serviceable to those who are beginning to take up the subject of alternate current as applied to the design of dynamos, motors, transformers and the operation of alternate current circuits.

After stating and explaining the fundamental laws and principles, the author takes up the experimental determination of e. m. f. and current waves, special application to sine functions, practical measurements of power, etc. The effects of phase displacement are very clearly pointed out as well as those of capacity.

Special chapters are devoted to the principles underlying transformer design, synchronous motors and parallel running of alternators, and to polyphase motor work.

As an introductory to other more advanced treatises on the subject the book ought to prove highly beneficial to the student. Examples for applying the principles taught are given throughout the work, and brief historical notes and references appended to each chapter enable the reader to find more extended information on the topics treated of.

ANDERSON'S PHYSICAL EDUCATION. By Dr. W. G. Anderson, Professor of Gymnastics at Yale University. A. D. Dana, publisher, 853 Broadway, New York. Price, 25 cents.

The book treats of every phase of body building and is "up do date" in every particular. There are special chapters devoted to professional people, business men, women and children. It tells how to decrease your weight if corpulent and increase it if thin. It gives valuable measurement charts for both men and women. Every reader interested in better health, greater strength, grace, self-control, elegant carriage, should possess a copy of this work. We know of no work that gives so many useful and helpful suggestions in such compact and readable form. The illustrations, about one hundred in number, are taken from drawings and life.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-1897. Edited by C. E. S. Philips, London, 1897. The Electrician Printing and Publishing Co., New York, D. Van Nostrand Co., 68 pp.; 5½ x 8½ inches. Cloth. Price, $1.50.

The title of this work explains its nature fully. The editor has evidently done his work very thoroughly and the short abstracts which accompany many of the references will be of material help to investigators and students. A short historical review accompanies the work, showing how various workers in the past contributed in one way or another to pave the way for Röntgen's great final discovery. The chapter devoted to practical hints in X-ray work, though short, is full of valuable hints. The frontispiece shows a group picture of the most prominent workers in the X-ray field. We can recommend the work very highly as a guide to the literature on the subject, the method of indexing being particularly well calculated to save time in the quest for work done in any particular department of the subject.

THE X-RAYS, THEIR PRODUCTION AND APPLICATION. By Frederick Strange Kolle, M. D. 250 pages, cloth, 50 illustrations, of which 12 are full-page, half-tone. New York: J. S. Ogilvie Pub. Co. Price, $1.

Dr. Kolle was one of the first medical practitioners in this country to take up Röntgen ray work, and has from the very start pursued his studies in that field with a great deal of energy and intelligence. He not only embodies X-ray data in this book, but furnishes a large amount of information as to the nature and use of electricity, going into a great many useful and interesting details on the subject. We believe that this book will be of great value, particularly to medical practitioners, photographers and serious amateurs.

TRASMISSIONI E DISTRIBUZIONI POLYFASI (Polyphase Transmission and Distribution). By Prof. Riccardo Arnò, Turin, 1897. Unione Tipigrafico-Editrice. 54 pp.; 5 x 8 inches. Paper cover. Price, $1.

This little work embraces the lessons of Prof. Arno, who succeeded Prof. Ferraris at the Electrotechnical Laboratory of the Royal Italian Industrial Museum, Turin. The author discusses briefly the various methods of polyphase distribution, describing the delta and Y connections, and special systems of distribution, such as those of Scott and the Steinmetz monocyclic system. Considerable space is also devoted to the Ferraris-Arno system of polyphase distribution and its various modifications.

SCIENCE ABSTRACTS. Vol. I., No. 1. Edited by J. Swinburne, London, 1898. Taylor & Francis. 50 pp.; 6 x 9 inches. Paper cover. Price, 36 shillings per annum.

This is the first number of a monthly publication issued under direction of the London Institution of Electrical Engineers and of the Physical Society of London. The plan adopted has been to divide the subject matter into departments under the following heads: General Physics; Light; Heat; Sound; Electricity; Electro-Chemistry and Chemical Physics; General Electrical Engineering; Dynamos, Power Distribution and Lighting; Telegraphy and Telephony. The abstracting has been very carefully done, Mr. Swinburne being assisted by no less than thirty-six abstractors. The value of a permanent record of this kind must be apparent, and we know that the efforts of the originators of this valuable aid to the technical reader will be appreciated by many busy workers.

MODEL ENGINES AND SMALL BOATS. By Nevil Monroe Hopkins. D. Van Nostrand Company, New York, 1898. Cloth. 74 pages. Price $1.25.

The mechanically and also nautically inclined youth will find in this interesting volume a mint of valuable information on the design and construction of small marine engines, of small steam cylinders without patterns and castings and boilers without the use of special tools. He will be enabled after a perusal of this book and aided by his mechanical ability to apply the methods here outlined in a general manner, embracing almost any type of model engine and boiler. A chapter on elementary boat design is given, followed by a system of hull construction, using wooden ribs in connection with cardboard plating. The book is written in a clear and fascinating style and is well and profusely illustrated. A similar book by the same author, dealing with the simple construction of electrical apparatus, would be welcomed as a valuable addition to electrical literature.

ROENTGEN RAYS

Radiography with its Recent Applications.[1]

BY PROF. ARTHUR W. GOODSPEED.

THE first step toward the X-ray tube was made many years ago by Geissler, who produced many curious and beautiful effects by exhausting the air from fantastically shaped glass tubes, and passing a high voltage current of electricity through the rarified gas within. A spark which can travel only nine or ten inches in the air, may in a Geissler tube, pass over a distance of thirty or forty feet. In the Geissler tube only about one-thousandth of the air is allowed to remain. Subsequently Crookes, of England, carried the exhaustion to a much higher degree than Geissler, allowing only about one-millionth of the original quantity of gas to remain in the tubes. On passing an electric discharge, the results were so different from anything ever observed before that Crookes felt impelled to speak of a

[1] Abstract of a paper read before the Electrical Section of the Franklin Institute.

gas in this state of rarefaction as the "fourth state of matter." It was while experimenting with Crookes tubes that Röntgen made his wonderful discovery.

The best authorities say that one cubic centimeter of air under standard conditions, contains 100,000,000,000,000,000,000,000 separate molecules flying around with inconceivable velocity in all directions, bumping against their neighbors and the inner surfaces of the containing vessel. By dividing this number by 1,000,000 we find that there are yet remaining in each cubic centimeter 100,000,000,000,000,000 molecules. This then represents the state of things within the tube where the X-rays are generated. Ordinarily the molecule of a gas can move only the smallest fractional part of an inch before striking its fellow molecule, but in the X-ray bulb, the mean free path of the molecule is several inches. When the discharge is sent through the tube, the molecules are projected with enormous velocity from the negative terminal, or cathode. The cathode is a spherical concave aluminum projector which directs the moving molecules against a small rectangular piece of platinum foil, placed at an angle of 45 degrees, in the centre of the tube. The molecular bombardment heats the platinum foil white hot, and if care is not exercised the foil may be melted, although it has a melting point very far above that of most other substances. It is here at the surface of the platinum that the X-rays are produced.

As to the nature of the X-rays, the consensus, at present, of the best opinions is that they are produced by transverse vibrations in the ether similar in nature to ordinary light, but of vibration frequency vastly greater.

According to Sir G. G. Stokes, in a paper read before the Manchester Literary and Philosophical Society last summer, "the Röntgen emanation consists of a vast succession of independent pulses, starting respectively from the points and at the times at which the individual charged molecules projected from the cathode impinge on the target. At first sight, it might appear as if mere pulses would be inadequate to account for the effects produced, seeing that in the case of light we have to deal with series consisting each of a very great number of consecutive undulations. But we must bear in mind how vast, according to our theoretical views, must be the number of molecules continued in the smallest quantity of ponderable matter of which we can take cognizance by our senses. Hence, small as is the quantity of matter projected in a given short time from the cathode, it may yet be sufficient to give rise to pulses, the number of which is inconceivably great."

The lecturer then showed a number of lantern slides illustrating the practical application of Röntgen ray photography.

News and Notes

A Use for Electric Light Carbon Ends.

At last a use has been found for the unburnt ends of carbon taken from electric arc lamps. Mr. Johnston, the foreman of the smiths' and wood-working shops of the Baldwin Locomotive Works, in Philadelphia, has recently instructed the man who changes these carbons in the lamps throughout the works to save the partly consumed pieces and bring them to him daily. He gets in this way some sixty or seventy carbon stumps which he utilizes for making a small charcoal fire of great heat and purity, suitable for any kind of special small work not interfered with by the copper coating on the outside of the carbons. Mr. Johnston having shown the way, others engaged in kindred lines of work ought to follow his example. It stands to reason that carbon prepared with so much pains to keep it pure and homogeneous, must be serviceable for some of the many uses for which charcoal is required. The copper coating might be an objection for some things, but if the collections of stumps were large enough, it might pay to remove the copper with nitric or sulphuric acid, thus getting an absolutely pure nitrate or sulphate of copper, for either of which there is always a practically unlimited demand in the arts.—Cassier's Magazine.

A Successful Failure.

A rather amusing incident took place several months ago in the yards of the Chicago Ship Building Co., which showed how a piece of electrical apparatus could be at once both a success and a failure.

The Chicago Ship Building Co., which has extensive yards for building lake vessels on the Calumet River at South Chicago, has, like all progressive concerns of the kind, introduced compressed air and electricity wherever possible in the process of ship construction. It has a power house in the centre of the yard where the dynamos and air compressors are located. One of the important uses of compressed air is for driving pneumatic hammers for deck calking on iron decks. In this process the hammer is fitted with a sharp tool which is made to follow the flush joint between the two plates and burr the corners over so as to make a water-tight joint. This was formerly done with a hand hammer and the workman held the tool in one hand and hammered with the other. When the pneumatic calker was first introduced the workmen saw in it one of those much to be shunned devices to enable one man to do the work formerly done by five or six, and they immediately discovered that it was impossible to follow a seam with a pneumatic calker and that the tool wandered all around the adjacent plate in a most unaccountable manner. As there was no opportunity to fasten a guide to the smooth deck by a mechanical clamp the management of the yard was in somewhat of a quandary until the company's electrician came to the rescue with a magnetic clamp furnished with a guide which could be set anywhere on the deck and would hold fast as long as the magnets were excited. When this was given to the workman with the pneumatic calker he of course found no difficulty in following the seam because he had a straight edge to guide him. The remarkable part of the proceeding followed, however, when the workman further found he could follow the seam without the aid of a straight edge and magnetic clamp and didn't care to bother with the clamp. The consequence is that the clamp now resides in the scrap heap; but who will say that it did not accomplish a useful object, and surmount an obstacle, even if that obstacle was the objection of workmen caused by opposition to labor-saving devices.

Electricity and Gas in Massachusetts.

The thirteenth annual report of the Massachusetts gas and electric light commissioners for 1897, has just been issued. It covers the operations of 134 corporations, of which 45 are gas companies, 24 gas and electric light, and 65 electric light, for the year ending June 30. The earnings of the gas companies compare as follows:

	1897.	1896.	1895.
Gross	$6,046,747	$6,043,652	$5,280,887
Expenses	4,140,762	4,219,254	3,770,751
Net	1,905,985	1,824,398	1,510,136

Those of the electric light companies are as follows:

	1897.	1896.	1895.
Gross	$4,510,134	$4,187,260	$3,822,196
Expenses	2,888,477	2,739,783	2,542,133
Net	1,621,656	1,447,477	1,280,062

Turin Exhibition of 1898.

International Electrical Section.—It has been officially announced that the exhibition authorities will give a premium called the "Galileo Ferraris Prize," amounting to 15,000 lire (about $3,000), to the person who will show at the exhibition an invention, a machine, an apparatus or a number of combined machines or apparatus, whose application will tend to advance the industrial application of electricity. Only those inventions will be considered which are shown at the exposition and which can be experimentally tested. Italians as well as foreign exhibitors can compete for this premium, the award of which will be decided by an international jury. This jury will be elected by the executive committee in conjunction with the Chamber of Commerce and will be completed by a choice of the leading commissioners of the International Electrical Section.

PROF. R. B. OWENS, of the Dept. of Electrical Engineering of the University of Nebraska, Lincoln, Neb., has now been appointed Director of the Bureau of Electricity of the Omaha Exposition, which opens June 10.

An Electrical Exhibition for Philadelphia in June.

Our readers will be interested to learn that the Philadelphia Electrical Exposition Company will give an electrical exhibition in its building, 818 and 820 Chestnut street, beginning June 6, 1898. It will last one month. There has been no such exhibition given in that city since 1884. Public interest will be aroused by a systematized attempt to place before it all the progress of electricity during the interval. Especial efforts have been made to interest distinguished inventors. While the exhibition will necessarily be commercial, no pains will be spared to make it of the highest scientific character and instructiveness. Much thought and time will be given to tasteful decorations and the best of music will be furnished. Many of the exhibits will be such as have never been brought before the public up to this day. The kinetoscope will be employed for a series of moving pictures of military and naval subjects of peculiar interest at the present moment. Extraordinary pains will be taken to have phonograph addresses from distinguished men delivered at stated hours. The management has obtained the services of Prof. William D. Marks as director. His former experience as manager of the Franklin Institute exhibition and his intimate knowledge of the advances in electricity will be guarantee that nothing of interest in the latest advances of scientific discovery will be omitted.

OBITUARY

Jules Viennot.

Jules Viennot, a well-known Philadelphia business man, died in that city on March 11 after a brief illness, in his 73d year. Mr. Viennot was born in Paris and came to this country about 40 years ago. Some 20 years later he reached and established himself in business in Philadelphia. He was a member of the Franklin Institute and of the French Benevolent Association. About two years ago he had the honor of Officier de l'Academie bestowed upon him by the French government. Mr. Viennot conducted one of the largest advertising agencies in the country, and by his strict integrity and upright dealings he had been able to number among his clientage numerous large firms. A widow and daughter survive him.

Sir Henry Bessemer.

Sir Henry Bessemer, F. R. S., known the world over by the invention of Bessemer steel, died in London, England, March 14. He was born in Hertfordshire, and early developed a talent for modeling, designing and mechanical invention. At the age of 20 he was an exhibitor at the Royal Academy. His discovery of the means of rapidly and cheaply converting pig iron into steel, by blowing a blast of air through the iron when in a state of fusion, was the result of costly and laborious experiments, which extended over a long period, and in which the end was attained only after many and disheartening failures. The development of the process has been of incalculable value to the iron industries of the world, and Bessemer reaped a fortune from it, as well as marks of distinction from the crowned heads of Europe and from scientific and learned societies. In 1871 he was president of the Iron and Steel Institute and later was made a Fellow of the Royal Society. He was knighted in 1879. He was a member of the American Society of Mechanical Engineers and the American Institute of Mining Engineers. In this country, towns in Alabama and Michigan were named after him.

PERSONAL

MR. LOUIS B. MARKS, E. E., of the Pioneer enclosed arc lamp, has gone abroad for a few weeks.

MR. T. A. EDISON, JR., who was ordered away to Florida for his health, has now returned to New York after a prolonged stay and is much better for the change. He had heard of our early spring and was greeted Monday morning by a thick snowstorm.

MR. W. M. MORDEY, Mr. R. Percy Sellon and Mr. C. E. Hodgkin, so well known in connection with Anglo-Brush interests, are now in this country for a few weeks studying our recent developments in electrical engineering.

MR. F. P. FISH, general consul of the American Bell Telephone Company and General Electric Company, has gone to Europe on a short business trip.

MR. C. L. EDGAR, vice-president of the Boston Edison Company, has sailed this week for Europe on the Normannia, to be gone about three months.

PROF. E. P. ROBERTS, of Cleveland, was a welcome visitor to New York last week. He is busily engaged on a large amount of consulting electrical work, and is building a large electric road in the vicinity of Dayton, O.

SOCIETY & CLUB NOTES

American Institute of Electrical Engineers.

The 123d meeting of the Institute will be held at 12 West 31st street. New York City, on Wednesday, March 23, 1898, at 8 o'clock p. m. A paper will be presented by Prof. Reginald A. Fessenden of Allegheny, Pa., on "Insulation and Conduction."

Chicago Electrical Association on Copper Wire Manufacture.

THE Chicago Electrical Association held a very interesting meeting the evening of March 18, the subject for discussion being the manufacture of copper wire. Mr. C. T. Gage of the Washburn & Moen Company read the paper of the evening. He traced the history of a piece of wire from the mines to the consumer. The Lake Superior copper deposits were explained and the process of mining there used. The Lake Superior miners find copper in its pure native state scattered in small particles through the rock. After following the copper to the wire mill, where it is rolled into rods and then drawn into wire, he took up the different coverings used on electric wires, giving their derivation and process of preparation. C. H. Sewall, in the discussion of the paper, spoke a word in favor of jute and paper versus rubber insulations for electric light and power underground cables. He said that the impression that such insulations would give out the moment the lead covering was broken was not based on fact. The jute or paper insulations being thicker, offered more obstruction to static discharges. Mr. Scheible questioned the statement that pure ozokerite is the only compound used on weatherproof wire. Wire factories, he said, used large quantities of asphalt, and he didn't know what it could be used for unless it was for weatherproof wire. He mentioned the importance of curing the rubber cores of wires under pressure.

At the next meeting of the association, April 1, H. H. Cutler will lecture on "Motor Regulation and Protection," and it is expected there will be a large and interested attendance.

Northwestern Electric Light Convention.

At a meeting of the committee having in charge the summer meeting of the Northwestern Electric Light Convention—present Messrs. Norcross, Korst, Doherty and Hill—the following resolution was put to vote and unanimously carried:

Resolved, That as a committee of the Northwestern Electrical Association, we accept the invitation of the cities of Duluth and Superior to visit those cities next June.

That Mr. J. M. Hill of Chicago is authorized by this committee to make arrangements with any steamboat company for a summer meeting of said association, to be held en route from Chicago via Sault Ste Marie, Hancock and Houghton, to Duluth. P. Norcross, chairman; P. H. Korst, Henry L. Doherty, J. M. Hill.

NEW YORK HARBOR. Cables and land telegraph lines are being laid and built to connect all the fortifications in the vicinity of New York and the bay and sound.

ELECTRICAL EXHIBITION. FROM MAY-2 TO MAY-31-

Novel and Interesting Features for the Show.

MR. FRED CATLIN, the manager of the telegraphic tournament, has completed the preliminary arrangements for that contest and has arranged the classes. Circulars on this subject will be ready this week for general distribution, and there is already a great demand for information on the subject from all parts of the country. Mr. Catlin informs the exhibition management that the entries will probably be more numerous than at any other tournament that has occurred and thinks that some of the records will be phenomenal. It is proposed, in addition to the regular contest, to have interesting exhibits of telegraphic skill in novel directions. Mr. Jesse H. Bunnell, the electrical manufacturer and veteran operator, is taking a deep interest in the contest and has volunteered to equip the whole stage with the necessary apparatus for the competition, in the shape of keys, sounders, batteries and auxiliary appliances. Mr. Bunnell is desirous to have a separate prize offered for an "old-timers' class," and has already entered himself for that contest. He has the reputation, dating from the war, of being an unusually fast and skilful operator.

Mr. H. V. Parsell, the well-known banker of this city, who has long been interested in electric deposition work, has kindly placed in the hands of his son, Mr. H. V. Parsell, Jr., the electrical engineer, for exhibition at Madison Square Garden during May, a marvelous collection of galvanoplastic work, done during a long series of years. It may be doubted whether any other amateur could possibly show anything approaching this remarkable collection in beauty and interest. It will not only include several striking pieces, as large as 25x25 inches, and reproducing celebrated works of art and famous men, but will comprise large number of coins, medals and fac-similes of antique gems. The most extraordinary part of this beautiful collection, however, will be that which embraces the reproductions from natural objects. It is safe to predict that there will be a crowd around these exhibits all the time. The manner in which they are made, for example, is of deep interest. There are, for instance, snakes and frogs which have been made to the life and from the life. The snake is etherized under a bell jar, then taken out and greased with sweet oil and replaced in the bell jar, while a sufficiency of thin plaster is mixed with warm water. The snake is then placed on a glass plate and posed. Around him is built an enclosure of four square bars, and the plaster is slowly poured over the snake, the bars confining the cast in a rectangular shape. When the plaster is hard it is freed from the sticks and glass plate and the now defunct reptile is carefully removed, tail first, from his intaglio impression. The plaster cast thus obtained is rendered waterproof by immersion in molted paraffin. A metallic conducting surface must now be given to the interior of the cast. This is done by moistening the surface of the mould with a solution of silver nitrate and by exposure to sulphuretted hydrogen, precipitating the silver on the cast. A conducting wire is now fastened around the edge, and the mould is carefully suspended in the depositing bath. A good, firm coating takes about three days to form, and then the mould is softened in boiling water and carefully broken off.

People have often heard of the incinerating effects of high frequency currents, but rarely get any practical demonstration. The attention of the electrical and popular press has lately been drawn to the grim fate of various birds that had, in an unfortunate moment, perched on some of the high tension wires of the power transmission circuits in California. Mr. George P. Low, the well-known electrical engineer of San Francisco, has preserved the remains of two eagles, some storks and other birds, which had short circuited part of the current while sitting on the wires, with the result of leaving only their beaks and talons, not a vestige of their bodies or feathers being discovered. Mr. Low is forwarding these curious relics to the electrical exhibition, where they will be mounted in such a position as to show how the thing happened and just what happened. It will be the first exhibition of the kind that has ever been made.

It is proposed at the exhibition to have amongst other railway apparatus a working model of track intended to demonstrate the operation of the third-rail system as applied to steam railroads. Colonel N. H. Heft, the electrical engineer of the N. Y., N. H. & H. Railway Company, whose work is so widely known in connection with the successful third-rail line between Hartford and New Britain, Conn., has very kindly placed at the disposal of the management blue prints showing the construction of the track and some of the actual material used. The model track, from 50 to 100 feet long, single and double, and about 5 inches gauge, is now being constructed on Colonel Heft's plans, and will be shown in actual operation during the continuance of the show, the details of the track being imitated as closely as the conditions will allow. Over this track a train of cars will run to and fro continually, showing how the current is picked up and delivered to the motor and how the switches and signals are included in the operation.

LEGAL NOTES

The Shaw Three-Motor Electric Crane Patent Declared Void.—The Shaw Electric Crane Co. vs. Shriver.

THIS case came up before the U. S. Circuit Court of Appeals upon an appeal by complainant from a decree of the Circuit Court, Southern District of New York, entered March 16, 1897, dismissing the bill. The suit was brought for infringement of letters patent of the United States No. 430,487, granted to Alton J. Shaw, June 17, 1890, for an electric crane. The patent came first before Judge Acheson, sitting in the District of New Jersey, in a suit by the same complainant against Henry B. Worthington, incorporated, charging infringement of the first, second and tenth claims of the patent. It was held void for want of invention in an opinion, which will be found in 77 Fed. Rep., 992. The suit in the Southern District of New York charged infringement of the first and third claims; the Judge who heard the case followed Judge Acheson's decision and wrote no opinion.

The U. S. Circuit Court of Appeals, in its opinion, says: The record is a most voluminous one, covering 1,700 printed pages; six experts of unquestioned ability have been examined, three on a side; the briefs are able, ingenious and exhaustive, and yet, when the record has been read, the briefs studied and the testimony of the experts analyzed, it is apparent that the question presented is, after all, a single one, which may be answered without any extended discussion. Indeed, it seems unnecessary to add anything to the brief opinion of the Court in the District of New Jersey. The claims in question are: "1. In combination with a supporting track, a bridge mounted and movable thereon, a trolley or car mounted and movable upon the bridge, a hoisting drum or pulley carried by the trolley, and three independent electric motors, each in communication with a source of electricity, one of said motors being carried by and serving to propel the bridge, and the other two being carried by the trolley and serving respectively to propel the trolley and to actuate the drum or pulley.

"3. In a traveling crane, the combination of a bridge, an electric motor carried by and serving to propel the same, a trolley mounted upon the bridge, and an electric motor carried by the trolley wholly independent of the first and serving to propel the trolley over the bridge."

After discussing the evidence, the Court of Appeals quotes the conclusion of the Circuit Court, expressed in Shaw Electric Crane Co. vs. Worthington, that: "The differences between the cranes of Force and Newton and the crane of the patent in suit are simply such as would naturally be made in changing the motive power, and whatever of superiority over previously used traveling cranes is to be found in the crane of the patent is due altogether to the recognized advantages inherent in the electric motor."

The decree of the Circuit Court was affirmed with costs.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued March 8, 1898.

Alarms and Signals:—

GAGE ALARM. H. Cunderman, Brookfield, Wis., 600,244. Filed July 7, 1897. The pointer makes contact to close an electric circuit when it reaches a predetermined point on the dial.

SIGNALING APPARATUS. V. K. Spicer, Kenilworth, Ill., 600,384. Filed April 27, 1897. A combination of mechanical devices whereby a suitable motor may be put into operation for shifting the signal to safety position and to lock it in such shifted position, the locking and shifting mechanisms being controlled by train movements.

SIGNALING APPARATUS. V. K. Spicer, Kenilworth, Ill., 600,385. Filed July 13, 1897. Automatic signals for railways; details of construction.

Batteries, Primary:—

GALVANIC APPARATUS. G. H. A. Schaefer, Buffalo, N. Y., 600,380. Filed January 7, 1898. An arrangement and combination of batteries, connecting wires, switchboard, and inclosing cabinet, in which economy of space and portability are considered.

ELECTRICAL BATTERY. N. B. Stubbelfield, Murray, Ky., 600,457. Filed October 24, 1896. A battery for use with water as an electrolyte, comprising a voltaic couple of insulated copper wire and bare iron wire closely wound into a coil body.

Conductors, Conduits and Insulators:—

INSULATING CONNECTION. H. E. Pearce, Brooklyn, N. Y., 600,336. Filed May 18, 1897. Embodies a top bracket formed with a hub, whose opening is larger than the diameter of the supporting pipe, and set screws in the hub for attaching the connector.

ELECTRICAL INSULATOR AND METHOD OF MAKING SAME. J. W. Boch, East Liverpool, Ohio, 600,475. Filed Oct. 23, 1897. Comprises two or more parts of clay, coated with glazing material, fitted together, supplying extra glazing material at the joints between the petticoats and firing the united and coated parts with the petticoats uppermost. See description on page 330.

Distribution:—

POLYPHASE CURRENT TRANSFORMER. C. Kurda, Nuremberg, Germany, 600,228. Filed Nov. 5, 1896. Consists of two or more sets of inducing coils of different phase placed one upon another, in combination with laminated sheet-inductive material surrounding the sets of inducing coils and separating them from each other.

Electro-Metallurgy:—

APPARATUS FOR WASHING AMALGAM. H. C. F. Störmer, Christiana, Norway, 600,211. Filed June 26, 1895. Comprises a vessel containing a layer of mercury as cathode and an anode, a mixer consisting of a plate normally immersed in and of the same superficial area as that of the cathode, and means for imparting to the plate a reciprocating motion.

TREATMENT OF METALLIFEROUS ORES AND PRODUCTS. E. A. Ashcroft, Melbourne, Victoria, 600,351. Filed Feb. 4, 1897. Consists in circulating a zinc bearing solution around the metallic cathodes of an electrolytic apparatus, the anodes consisting of the matte of the products resulting from the preliminary furnace treatment of products or ores containing copper and iron.

Electro-Therapeutics:—

ELECTRICAL SURGICAL ENGINE. A. W. Browne, Prince's Bay, N. Y., 600,135. Filed Oct. 19, 1897. Details of construction.

THERAPEUTIC ELECTRODE EXERCISING APPARATUS. A Martin, Paris, France, 600,230. Filed Nov. 23, 1897. Embodies a counter with a graduated spring balance for indicating the power developed.

THERAPEUTIC ELECTRODE. J. S. Muir, San Francisco, Cal., 600,290. Filed Aug. 24, 1897. Consists of an electro-chemical decomposing cell of porous material adapted to contain an electrolytic fluid, and electro-conducting rod extending thereinto, and means whereby a current may be passed through the electrolyte within the porous cell.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. J. H. Duncan, San Francisco, Cal., 600,277. Filed July 13, 1897. Comprises a fixed upper frame carrying the actuating magnets, upper carbon and clutch mechanism therefor, a lower movable frame normally upheld by the spring carrying the lower carbon and acting as a trip for the clutch mechanism and connections, whereby the lower movable frame is controlled by the actuating magnets.

Measurement:

ELECTRICAL MEASURING INSTRUMENT. A. H. Hoyt, Penacook, N. H., 600,265. Filed July 2, 1897. Comprises a graduated scale and a pointer whose movement thereon is caused by the current on the circuit, and suitable mechanism for preventing a return movement of the pointer to zero should the current be diminished.

Miscellaneous:—

ELECTRIC HEATER. R. J. Holland, New York, 600,285. Filed Dec. 24, 1896. Provides a flexible liquid-holding receptacle, with an electric heating apparatus adapted for applying local heat uniformly to any particular part of the body.

AUTOMATIC REGULATOR FOR ELECTRIC CURRENTS. J. D. C. Chateau, Paris, France, 600,356. Filed July 10, 1897. An apparatus for lighting and extinguishing gas burners at a distance.

ELECTRIC HEATER. E. E. Gold, New York, 600,417. Filed Aug. 12, 1897. Comprises a helix of resistance wire coiled into a compound helix combined with a support therefor, the helix being compressed against the support so that it exerts an expansive tendency.

Railways and Appliances:—

TROLLEY WIRE SYSTEM. W. J. Kauffman, E. W. Conkell and O. F. Kaufman, Canton, Ohio, 600,202. Filed June 5, 1897. Details of construction.

ELECTRIC RAILWAY. J. F. Scherpe, deceased; L. Scherpe, administratrix, St. Louis, Mo., 600,381. Filed Aug. 12, 1897. Relates to sealed switch boxes for underground trolley electric railways.

MEANS FOR ARRESTING MOTION OF ELECTRIC CARS. W. C. Anderson, West Hoboken, N. J., 600,252. Filed Aug. 30, 1895. The principle employed is that of converting the motors into generators and consuming the momentum of the cars in driving the generators upon a closed short circuit.

Classified Digest of U. S. Electrical Patents Issued March 15, 1898.

Alarms and Signals:—

AUTOMATIC FIRE ALARM. R. J. Baker, Baltimore, Md., 600,765. Filed April 28, 1897. Employs thermostats to complete circuit.

Batteries, Primary:—

GALVANIC BATTERY. E. Habermann, Michigan City, Ind., 600,719. Filed October 7, 1897. Comprises superposed battery elements, a wick disposed between and in contact with both elements, and an exciting fluid isolated from the elements and in which a portion of the wick is immersed.

PRIMARY BATTERY. J. E. Fuller, New York, 600,850. Filed April 5, 1897. Strong solution battery designed for operating bicycles or carriage lamps.

Batteries, Secondary:—

METHOD OF MAKING SOLUBLE METAL ELECTRODES FOR ACCUMULATORS. J. Julien, Brussels, Belgium. Consists in depositing on a copper plate, by electrolysis, a finely-porous surface of pure copper, then amalgamating the copper surface so produced, and finally depositing on the amalgamated surface a coating of zinc to form the active surface of the electrode.

Conductors, Conduits and Insulators:—

INSULATOR SUPPORT FOR ELECTRICAL CONDUCTORS. F. Benedict, Niles, Mich., 600,607. Filed September 13, 1897. Consists of a clamp comprising a plate, a strap secured to it by a bolt, an insulator secured upon the upper end of the bolt and a cross-piece secured to the lower ends of the strap.

Measurements:—

ALTERNATING CURRENT METER. G. Hummel, Munich, Germany, 600,616. Filed October 30, 1897. Consists of an alternating current meter of the Ferraris motor type, wherein a lag of approximately 90 degrees between the main and shunt magnetizing influences is brought about without the necessity of introducing a separate inductive resistance.

Railways and Appliances:—

CONTROLLER FOR ELECTRICALLY PROPELLED VEHICLES. R. T. D. Brougham and W. C. Bersey, London, Eng., 600,509. Filed December 13, 1897. Comprises a switch lever having a slot in it, a foot lever carrying a pin working in the slot, a brake-lever and a flexible connection between the foot and brake levers.

DEPRESSIBLE RAIL SYSTEM FOR ELECTRIC RAILWAYS. W. Grunow, Jr., Bridgeport, Conn., 600,527. Filed April 12, 1897. A contact receptacle is employed containing mercury, the depressible rail being movably supported above the receptacles upon the upper portion of a reciprocating contact device, adapted to be depressed into the mercury.

PROTECTIVE APPLIANCE FOR ELECTRIC RAILWAYS. L. E. Walkins, Springfield, Mass., 600,564. Filed July 17, 1897. Consists of parallel girders supported by pillars, one on each side of the third rail, and being separated by four inches of space at their inner edges.

Switches, Cut-Outs, Etc:—

QUICK-BREAK ELECTRIC SWITCH. T. E. Drohan, Chicago, Ill., 600,523. Filed November 13, 1897. Embodies an auxiliary blade to divert the current from the main contacts at the time of breaking the circuit.

CUT-OUT. A. R. McNeill, Oldfields, W. Va., 600,593. Filed October 7, 1897. Designed for telegraph and telephone circuits and provides means whereby any single instrument may be cut out at the owner's pleasure and the main line be closed.

AUTOMATIC SAFETY CIRCUIT CLOSER AND CUT-OUT. W. L. Pratt, Adams, N. Y., 600,743. Filed May 13, 1896. Comprises a movable arm having loop connections, a fuse wire, a device acting as a magnet, a pivoted armature, and a needle which is caused to move by the armature, and a fuse wire having its ends bent so that the needle can make connections with either end.

PATENT NOTES.

Report on International Patents.

The full report of the conference of the Union for the Protection of Industrial Property, which met at Brussels in December last, has been received from the delegates representing the United States, Bellamy Storer, United States Minister to Belgium, and Mr. Francis Forbes, and is of marked interest. There were present at the conference not only delegates from fifteen of the States of the Union, but also from seven countries which have not yet adhered to it, among them Germany and Japan.

The propositions for amendment of the convention, submitted by the United States, looking toward reciprocity in the matter of fees and the requirements of working and the matter of invention belonging to certain classes, which are patentable in the United States, but not in certain other countries, were held by the conference to be contrary to the general spirit of the convention, but several solutions of the difficulties complained of were suggested which would not be obnoxious to it.

The United States delegates took an active interest in the discussion of changes proposed in the agreement respecting the

international registration of trade marks, though this country is not at present a party to it. The purpose of this agreement is to make the international bureau at Berne the center of a cheap registration which shall be efficient over the territory of the adhering States. Such a registration is regarded as extremely desirable, and is practically a necessity if our manufacturers are to be protected in their foreign trade.

Annexed to the report are a number of papers of great interest. Among these is a statement made by the German delegates, in which they urge the extension of the delay of priority to one year instead of seven months, and the abolition of forfeiture of patents for non-working.

Among the other papers is a statement showing the requirements as to working the invention made in certain countries. In some failure to manufacture the invention in the country within one year invalidates a patent. In others two years, or even three years, are allowed, and importation of goods made under the patent is prohibited. This means that the manufacturer of an American invention must establish factories in each of these countries, or give up patent protection in those countries, and is a very onerous requirement.

REPORTS OF COMPANIES

Hudson River Telephone Co.

At the annual meeting of the Hudson River Telephone Company reports were submitted showing that the company earned over 5½ per cent. during the year on its capital stock. The company has paid a regular quarterly dividend of 1 per cent., or 4 per cent. for the year. In the thirty-eight exchanges operated by the company, the aggregate number of subscribers increased from 5,454 to 6,488, a gain of 1,034. New exchanges were built at Northville, Philmont, Chatham, Coxsackie, Millbrook, Brewsters, Fonda and Wappinger's Falls, N. Y., and Newton, N. J. The most important work to be considered at once are additional circuits on new lines: Whitehall to Glens Falls, Saratoga to Albany via Schenectady, Saratoga to Schuylerville, with additional metallic copper circuit from Saratoga to Greenwich; Fonda to Canajoharie and Fort Plain; Albany to Schoharie; Middleburg and Cobleskill, and extending same from Cobleskill to Sharon Springs; building new line along the U. and D. R. R., from Kingston to Sing Sing, Poughkeepsie to Newburgh, Middletown to Monroe, Middletown to Warwick, Middletown to Ellenville, Port Jervis to Newton, N. J., via Milford, Pa.; Tuxedo to Sufferns, Newton, N. J., to Stanhope, N. J.; Milford, Pa., to Bushkill, Pa.; Port Jervis, N. Y., to Honesdale, Pa., and Catskill to Saugerties.

Annual Report of Electric Storage Battery Co. of America.

The Electric Storage Battery Company issues this statement for the calendar and fiscal year 1897:

Shipments	$842,963.09
Manufactured products sold and not yet shipped	101,594.35
Materials, in process and stock on hand, increase over 1896	14,476.22
	$959,033.66
All expenses, taxes and interest	633,742.74
	$325,290.92
Income from royalties and investments	14,718.07
Net profits	$340,008.99
Fixed charges, interest on bonds	18,200.00
Net income	$321,808.99
Charged off for depreciation	64,064.57
Net surplus	$257,744.42

Sales were $1,026,925.65 in 1897, against $572,281.56 in 1896, increase $454,644.09; net profits $340,008.99, against $148,799.60, increase $191,209.39. The company has $4,000,000 preferred stock on which 3 per cent. dividends have accumulated, and $8,500,000 common stock, the only debt being $450,000 5 per cent. bonds. The year's net income would allow payment of 3 per cent. on common, but the business has developed enormously, and the money probably will be used in its extension.

THE STOCK MARKET

A Firm But Anxious Market.

Another week full of anxiety, rumor and sensation has been gone through, and still others appear to be ahead; but the stock market, wonderful indicator of the national pulse, remains very steady. The general condition of trade is also excellent. During the past week 16,200 shares of Western Union were sold around 85½. General Electric, on sales of 17,690 shares, rose from 30⅝ to 32⅝. In Boston, American Bell Telephone declined to 244½, on sales of 982 shares, and copper stocks there also declined sharply, despite the briskness in that metal.

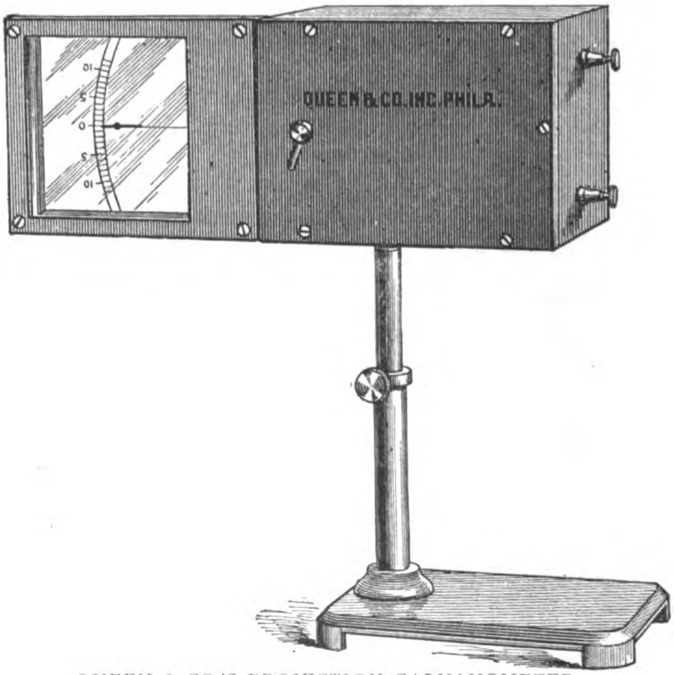
Copper is now quoted at 12 cents per pound, and seems likely to stay up. Heavy steel rail, Eastern mill, is quoted at $17.50.

A certain activity has been given to various branches of electrical manufacture by the demands for government work. Such orders are marked "rush" and have been given priority in execution. Export trade continues large, with new inquiries all the time.

TRADE NOTES & NOVELTIES

A New Queen Galvanometer.

A NEW galvanometer has been recently placed on the market by Queen & Company, Inc., of Philadelphia. It is termed a projection galvanometer and is designed for use in projection lanterns. As shown in the illustration, the galvanometer is attached to a telescopic support, enabling its height to be adjusted to that of the slide holder in the lantern. The scale is etched on plate glass and when projected on the screen is readily seen. The instrument is dead-beat, an important point



QUEEN & CO.'S PROJECTION GALVANOMETER.

when results are desired quickly and easily. The sensibility is very high, but it may be reduced with a shunt when too great. A series resistance enables the instrument to be adjusted to read directly in volts. A shunt resistance permits of calibrating it in amperes.

Those who have had occasion to use the projection galvanometer pronounce it a most convenient addition to the lecture room, and, moreover, when not desired for lecture purposes, the high sensibility and dead-beat character render it thoroughly suited to Wheatstone bridge measurements. When not used in the lantern a slip of paper behind the scale brings the numbers and graduations out plainly.

Some Western Electric 1898 Fan Motors.

THE Western Electric Company's desk, bracket and ceiling fan motors, shown in Figs. 1, 2 and 3, are made for 110, 220 and 500 volts, and are so designed that on a 500-volt circuit three 110-volt motors or two 220-volt motors may be operated in series with perfect safety to the motors, and the 500-volt motor can be operated on a 600-volt circuit continuously without

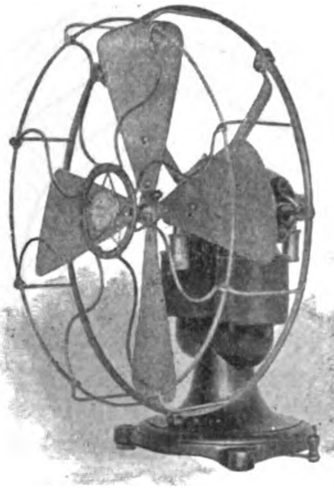


FIG. 1.—W. E. 1898 12-INCH FAN MOTOR, MADE FOR 110 VOLTS, DIRECT CURRENT.

injury. All of these motors are wound for three speeds and are made with self-oiling and self-aligning bearings.

On the desk and bracket motors the switch is placed in the base of the motor, whereas in the ceiling fans it is placed in a

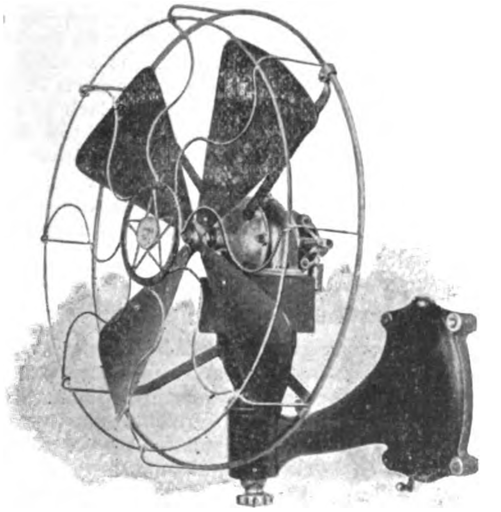

FIG. 2.—W. E. 1898 16-INCH BRACKET FAN MOTOR, MADE FOR 110, 220 AND 550 VOLTS, DIRECT CURRENT.

neat switch box on the under side of the motor casing. The desk and bracket motors are made in two sizes, the blades measuring 12 and 16 inches in diameter; they consist of four wings, it having been demonstrated that a four-blade fan is much more efficient than one with six blades. The current consumption of the 12-inch motors is much less than any 16 c. p. incandescent lamp on the market, while the current consumption of the 16-inch motors is but a trifle more than that required for the ordinary 16 c. p. lamp. The energy required by the 220 and 550-volt motors is practically the same as that required for the 110-volt motors. One very desirable feature is the facility with which the motors can be disconnected from the base and inserted in the bracket. The guard of the motor is made in a most durable manner and is firmly fastened to the motor, which prevents it from jarring. These motors are finished in polished brass, nickel plate or black enamel without additional charge.

All ceiling fans, one type of which is shown in Fig. 3, are so made that chandelier attachments can be readily put on, every motor being wired ready for the sockets, the lead wires being coiled in the top of the switch box when not in service. The

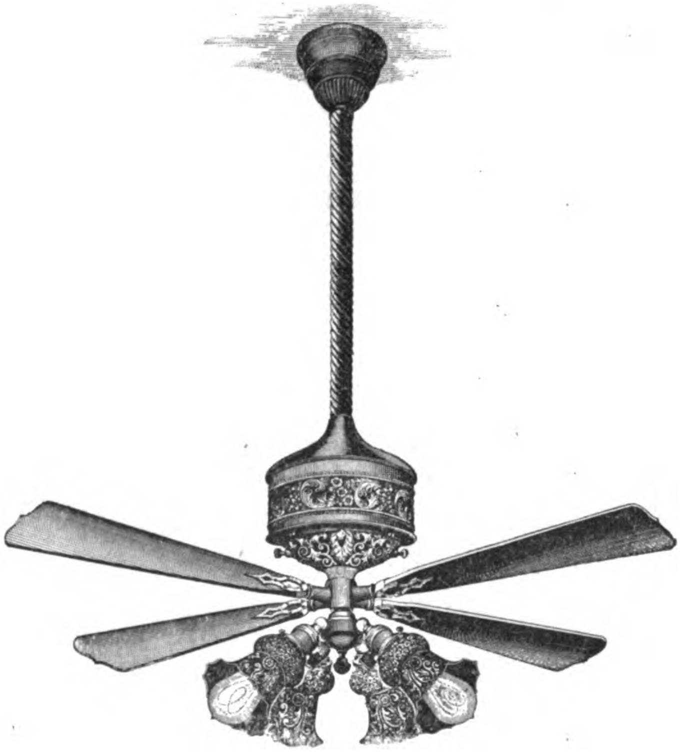

FIG. 3.—W. E. CEILING FAN, WITH LAMP ATTACHMENT.

standard fan consists of four blades, 60 inches in diameter and 8¾ inches wide, and runs at 175 and 185 r. p. m. If desired motors will be furnished with two blades, running at 210 and 215 r. p. m. These fans take but a trifle more current than that required for an ordinary 16 c. p. lamp. All motors are furnished with self-oiling and self-aligning bearings and are perfectly balanced. The stems from which the motors are suspended are usually adapted for 12-foot ceilings. These motors are finished in polished brass, oxidized copper or nickel plate, without additional charge. When ordered, motors will be furnished with one speed, these being made without the switch box and the speed controlling parts.

Carborundum and Some of its Users.

Many expressions and but one opinion are contained in a little pamphlet on "Carborundum and Some of Its Uses," issued by the Carborundum Company, Niagara Falls, N. Y. It contains testimonials from over forty representative firms who have used carborundum for roll grinding in place of emery and for the many other uses to which this splendid grinding material may be put.

Carr Mfg. Co's. Boiler Compound.

The Carr Manufacturing Company, 67 Beverly street, Boston, Mass., have for the past 50 years been manufacturing their superior boiler compound, known as the Yorkshire Boiler Compound, and which they offer to send on trial or approval, not to be paid for unless it gives perfect satisfaction. It may be used in boilers of every description and with all kinds of water, both on land and sea, and, it is claimed, has always been equally effective in removing the formation of scale, whether carbonate

of lime, sulphate of lime, or carbonate of magnesia. It is purely vegetable and it contains none of the injurious ingredients common to many boiler compounds. As a fuel economizer, therefore, its application must be patent to all users. Correspondence is solicited by the Carr Manufacturing Company from electric plants and power stations.

General Electric 1898 Fan Motors.

THE '98 models of the General Electric Company's fan motors are announced as the latest of a long line of successful designs. These fan motors are built for both alternating and direct current circuits.

That for alternating currents is an induction motor, as carefully proportioned in all its parts as are the larger machines which this company builds, excessive wear and heating under continuous operation being as absent from the small as from the large. To the cast-iron frame which supports a single long bearing, are bolted the soft iron laminations which make up the field core, provided with inwardly projecting teeth to form the poles on which are placed the field coils wound with an ample quantity of wire and thoroughly insulated. These are shown in Fig. 1. The armature, Fig. 2, is built up, also of soft iron laminations, assembled on a brass spider, but has no insulated wire. Bare copper rods run through the core, and are riveted into discs at each side. Rotation being produced by inductive action, no commutator or brushes are required. The armature overhangs the bearing, and with the fan, rotates well balanced on

Fig. 1.--Field Core and Coils.

Fig. 2.—Armature.

Fig. 3.—Self-Oiling Bearing.

Fig. 4.—Speed Regulating Device.

G. E. ALTERNATING CURRENT FAN MOTOR.

the single bearing. An automatic oiling device, shown in Fig. 3, gives perfect lubrication without oil throwing, and this, together with the long bearing, insures continuous cool operation. The alternating fan motor is built for 52 and 104 volts 60 and 125 cycles and is provided with a speed regulating device, shown in Fig. 4, consisting of an inductive resistance cut in or out by a three-point switch. Movement of the switch over the first two points gives full speed and half speed and on the third cuts the motor out of circuit. No additional switch is necessary.

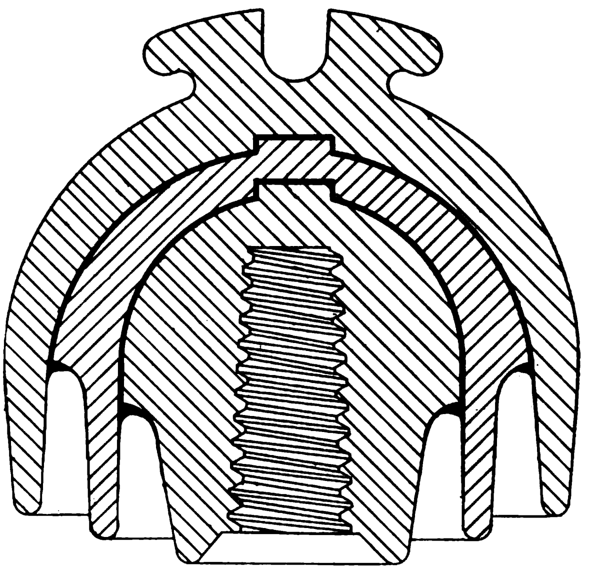
The direct current fan motor is equally as compact and carefully designed as that for alternating currents, and in appearance and general construction closely resembles it. Laminated soft iron of the best quality is used throughout for the magnetic circuit; all windings are thoroughly insulated, and commutator connections carefully made. As in the alternating motor, fan and armature revolve in a single, long, self-oiling bearing. The commutator is completely enclosed and the carbon brushes encased in small tubes, readily unscrewed for inspection. A regulating switch provides for variation of speeds. The alternating current fan motor may be, if desired, mounted on trunnions to allow of adjustment of the fan to blow in any direction.

The motors, which are illustrated in the General Electric Company's advertisement, are finished in black enamel, the fan guard and trimmings in polished nickel.

The Boch High Potential Petticoat Insulator.

A HIGHLY efficient insulator adapted for use on electric lines for the transmission of energy with currents of high voltage has recently been placed on the market by the R. Thomas & Sons Company. It is the invention of Mr. John W. Boch, and is illustrated in section below. It is built up of two or more separately molded parts of clay. The inner portion is pressed or molded with a thread for the reception of the usual pin, and the outer portion, shaped like an inverted bowl, is provided with a cross notch on the top for holding the conductor in place, and has side shoulders by which the conductor may be wired down.

The process of manufacture of the insulator is as follows: The separately molded parts, after coming from the press, are first dried out separately in an oven or kiln by the process known as "biscuit firing." When they have been thoroughly dried and are ready to be put into the vitrifying kiln they are each coated with a glazing material by dipping the portions into the liquid ma-



BOCH'S GLAZE-FILLED HIGH POTENTIAL PETTICOAT INSULATOR.

terial. The parts are then fitted into each other and are stood upside down. Glazing material is then put into the joints, that is, the annular channels between the petticoats. The portions are then put into a sagger with the petticoats uppermost and placed in a kiln, in which, under great heat, the clay shrinks and becomes vitrified, and the glazing material melts and becomes of a glass-like character, adding enormously to the insulation qualities. The glaze which was put into the annular channels flows into and fills all the spaces between the parts of the insulator, that is, such spaces occurring there by lack of correct fit of the parts or arising during the shrinkage by the vitrification of the clay. The extra glazing between the petticoats or at the joints prevents the formation of air spaces or cracks for the entrance of moisture. Every insulator, before it is shipped from the factory, is tested to 60,000 volts by using a specially constructed Westinghouse generator.

Becker Name Plates.

Mr. August Becker, an expert designer and engraver in steel, brass and other metals, of many years' experience, calls the special attention of manufacturers of machinery, electric motors, engines, etc., that he is prepared to furnish engraved name plate castings, index lathe plates and plates for patent dates, etc., in nickel or bronze. Mr. Becker is familiar with the difficulties in procuring thoroughly good designs, well-drawn lettering, clear, sharp and deep cutting. He has been identified with the business for many years, and eminently successful. Being himself a practical workman, and in possession of superior facilities, it is no vain boast to assert his ability to produce the very best work in all lines at the very lowest prices.

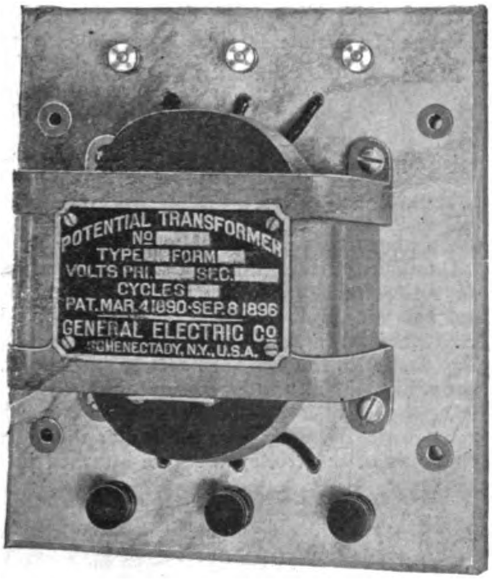
It is not often that the finest quality and the most reasonable prices unite on one article, nor is it frequent that the faculty to design is combined with the skill to engrave in one person. Mr. Becker gains an immediate insight into descriptions of proposed plates and carries out ideas with precision and speed, or invents

new designs as desired. This knowledge of the practical as well as the commercial side of artist's work is always of the highest value to the customer. All patterns are carefully adapted to the form of reproduction required, special pains being taken to obtain depth and clearance for casting in the sand. To those who may not have availed themselves of Mr. Becker's talents in this direction, undoubted reference can be given, sample plates shown, and information, drawings and estimates of proposed work furnished either by mail or interview. His facilities for producing large numbers of plates are unrivaled, and upon such orders he is pleased to make no charge for preparatory work. Mr. Becker would impress on the public mind most particularly the quality of his productions, no plate leaving his workroom without rigid inspection, and without possessing that fineness of finish and perfection of workmanship for which it is his pride to be distinguished. A call by mail or telephone will be responded to promptly, and prospective customers gladly welcomed at his address, 34 Oliver street, Boston.

General Electric Potential Transformers.

POTENTIAL transformers are designed to furnish current for either voltmeters or wattmeters. They are not of sufficient output to load with lights, and they give the correct ratio of transformation at their rated output instead of at no load, as is the case with all other transformers. The rating assigned them is 10 watts, which is ample to supply one General Electric inclined coil voltmeter and one single-phase recording wattmeter. They can be safely loaded to 50 or 60 watts for a few minutes and are thus adapted to furnish current to phasing lamps, in circuit long enough to synchronize the machines to which they are connected.

To meet various conditions the General Electric Company has designed five different potential transformers. The first, wound for 1,040 volts primary and 52 volts secondary for frequencies 60



GENERAL ELECTRIC POTENTIAL TRANSFORMER, 1,040 OR 2,080 VOLTS PRIMARY, 52 OR 104 VOLTS SECONDARY.

to 125 cycles, is intended for use on circuits the voltage of which does not exceed 1,250 volts, to supply current to indicating voltmeters reading to 75 volts and to primary recording wattmeters.

The second, shown in the figure, wound for 1,040 or 2,080 volts primary and 52 or 104 volts secondary, for frequencies of 60 to 125 cycles, furnishes current for indicating wattmeters reading to 75 or 150 volts, and is so wound that coupling the coils differently for use on different voltages is unnecessary. It has ample carrying capacity in the winding to give its full output on the lower voltages when only one-half of the winding is in use. Three primary and three secondary terminals are provided. If the transformer is used on 2,080 volt circuits the outside primary terminals are connected to the line. If, however, it is used on 1,040 volt circuits, the middle terminal and either outside terminal are connected to the line. By making similar connections on the secondary side either 52 or 104 volts can be obtained.

The third, wound for either 1,040 or 2,080 volts primary and 57½ or 115 volts secondary, for frequencies of 60 to 125 cycles, is identical in its construction and use with the second, except that it is wound for stations using a ratio of transformation of 1 to 9 or 1 to 18 in place of 1 to 10 or 1 to 20.

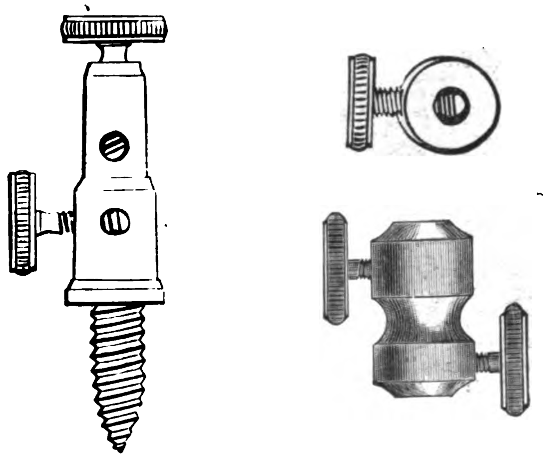
The fourth is so designed that it can be wound for any primary voltage up to 6,000 volts and any secondary voltage up to 115 volts, for frequencies between 60 and 125 cycles. As parts of this transformer are kept in stock, it can be wound on short notice.

The fifth is similar to that just described, but slightly larger. It can be wound for the same voltages, but has a range of frequency from 25 to 60 cycles.

These transformers are designed to supersede all station and meter transformers which have been built by the General Electric Company up to the present time.

The Binding Posts and Connectors Manufactured By the Springfield Machine Screw Co.

The Springfield Machine Screw Company, Springfield, Mass., have for many years been engaged in the manufacture of a full line of screw parts for electrical purposes. With the increasing demand for these goods, this company have from year to year been obliged to add new machinery to their factory to turn out what has now grown to be quite a large and varied line. The



SINGLE AND DOUBLE CONNECTORS AND BINDING POST.

line comprises such parts for electrical uses as connectors, switchboard parts, battery knurled nuts, telephone screws, binding posts of all descriptions and a large variety of special screws, nuts and studs. The accompanying cuts represent their single and double connector and binding post. The Springfield Machine Screw Company solicit correspondence from electrical concerns interested in the line of goods which they manufacture.

The Mica Insulator Co.

The Mica Insulator Company of New York, Chicago and London announce that they have recently made an addition to their already extensive line of oiled cloth and paper insulations and are now prepared to furnish "M-I-C Compound" rope and bond paper. This line of insulation is made from the finest grade of rope and bond paper and treated with two baked coatings of M-I-C compound. The rope paper is furnished in sheets one yard wide, two yards long, and carefully packed between sheets of plain paper. The average break down test is 739 volts per mill. Thickness, 4½ mills. The bond paper is furnished in sheets 19x24 inches and 22x34 inches, the average break down test being 859 volts per mill. Thickness, 5 mills. The company will be pleased to send samples to electrical manufacturers, street railways or lighting stations upon application.

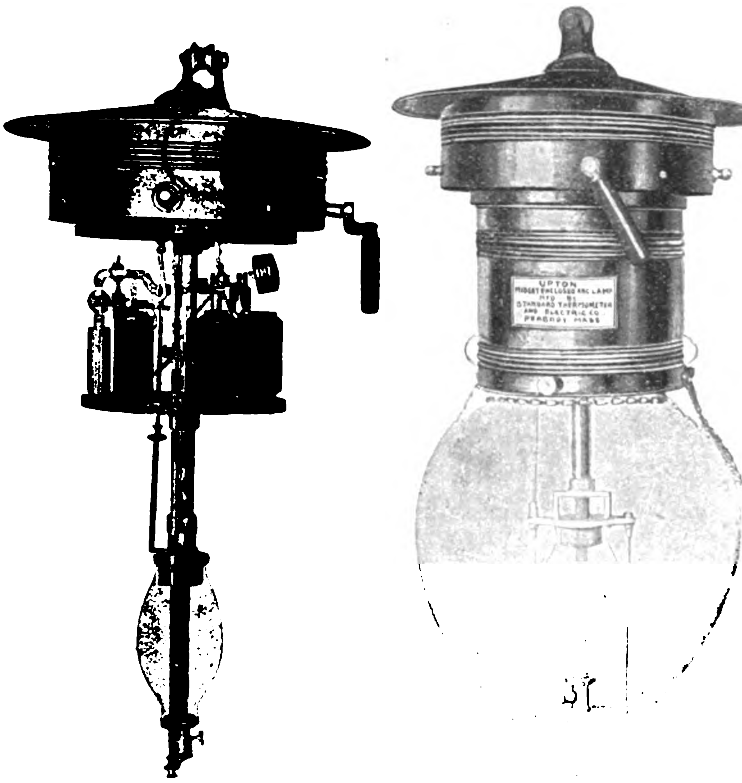
The Rae Motocycle Co.

The many friends of F. B. Rae of Chicago will be interested in knowing that he is becoming interested in the manufacture of motor carriages. The Rae Motocycle Company was recently formed for this purpose. Mr. Rae has a number of novel features which he expects to incorporate in the new electric vehicles, and electric carriage men will await their production with in-

terest. The Rae motor will be used, supplied from the Porter storage battery. The Sterling Cycle Company will build the running gear, so there will be no doubt as to the quality of workmanship.

Upton "Midget" Enclosed Arc Lamps for Direct Current to Burn in Series.

SO complete is the line of arc lamps and special arc lamp appliances placed upon the market by the Standard Thermometer and Electric Company, of Peabody, Mass., that we have been able to publish each week lately some novel type of lamp designed by this company for use on various circuits. The Upton "Midget" enclosed arc lamp, now illustrated in Figs. 1 and 2, is designed to burn two in series on 200 to 250 volt circuits, four in series on 440 volts, five in series on 500 to 600 volts, or five in series on railway or power circuits varying from 450 to 550 volts. Each lamp is provided with sufficient resistance, placed in the cover, to allow of its arc being extinguished without affecting the operation of the remaining lamp or lamps in the series. In case of accident to any one or more lamps of a series, by reason of carbons sticking or similar trouble, the lamp automatically cuts in resistance through which current will flow instead of across the arc. This device does away with the trouble and expense of burnt-out magnets and shunt coils. The lamps will burn 125 hours with one set of carbons, are adjusted and tested under exactly the conditions that they will be used, a rise or drop in the voltage affecting all equally. They are made to take from 3 to 6 amperes as desired. The parts are interchangeable and no soldered connections are used.



FIGS. 1 AND 2.—THE UPTON "MIDGET" DIRECT CURRENT ENCLOSED LAMP FOR SERIES CIRCUITS.

A large number of these lamps are now in use on railway and power circuits and after the most severe tests have proven their efficiency. Street railway companies are enabled to use these lamps five in series on their trolley circuits, as the "Midget" lamps are being operated on circuits showing a variation of 50 to 150 volts. This lamp is also recommended for factories and foundries using 220-volt power circuits, where the lamps can be operated two in series.

JANDUS ELECTRIC COMPANY, Cleveland, O., report that the Navy Department, Washington, has placed a very large rush order with them for Jandus enclosed arc lamps.

"H. W. J." Arc Lamp Hanger.

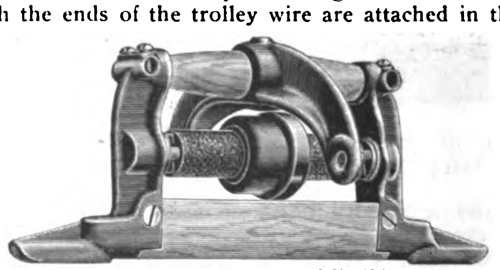
THE "H. W. J." lamp hanger illustrated herewith has been placed upon the market to meet the demand for a practically indestructible, highly insulated and reliable substitute for the porcelain and other arc lamp suspension devices possessing well-known disadvantages. The hanger is furnished with either sister hooks, similar to those illustrated, or with snap hook for the attachment of the eye or fastening at the top of the lamp, with an ample margin of strength to guard against any possibility of the lamp falling to the ground. The hanger with sister hook suspension will support 2,000 lbs. The sectional view shows the internal arrangement of parts, which are thoroughly insulated from each other by sheet mica and further insulated and waterproofed by the filling and exterior shell of moulded mica. Samples submitted to tests at 15,000 volts (the highest obtainable at the time) showed no effects. When immersed in water to the edge of the skirt, samples broke down at 7,000 volts.

"H. W. J." ARC LAMP HANGER, ELEVATION AND SECTIONAL VIEW.

The "H. W. J." arc lamp hanger is sold by the H. W. Johns Manufacturing Company and large sales are anticipated, as the merits of the device become better known. With inexpensive modifications the hanger can also be adapted to serve as a telephone or telegraph cable insulator and for special purposes.

The Hartford "Break."

A section insulator to be practical must be highly insulated, possessed of sufficient strength to withstand all strains of the trolley wire without distortion or fracture, should furnish an unobstructed passage for the trolley wheel and should provide simple and inexpensive means for repairing the parts subjected to wear. The design of the Hartford section insulator, shown in the illustration, is such as to meet these requirements. The tension of the trolley wire is resisted by steel bolts insulated by moulded mica, which securely binds together the end castings, to which the ends of the trolley wire are attached in the usual manner. The top wooden bar resists all strains of compression and completes the strongest form of a frame for the purpose required. The lower wooden bar, which furnishes the insulated run-way for the trolley wheel is held by screws in sockets in the end castings. The bar is, therefore, readily replaceable, when worn, without disturbance to the line, and the section insulator made as good as new by the insertion of a cheap piece of wood. The break is light in weight, is furnished with various suspensions to meet the conditions of line construction, and will undoubtedly attract the attention of all those interested in trolley line insulation and maintenance.



THE HARTFORD "BREAK."

The Hartford section insulator has been placed upon the market by the H. W. Johns Manufacturing Company.

Installations of Erie Ball Engines.

The electric light plant now being placed in the new building of the Peruna Drug Manufacturing Company at Columbus, O., consists of two Ball engines of 160 h. p., built by the Ball Engine Company, Erie, Pa., direct connected to Siemens-Halske dynamos.

The "City of Erie" is the name of a new passenger steamer now being built at Detroit for the Cleveland and Buffalo Transit Company. This boat, which will be one of the most handsomely fitted out on the Great Lakes, will have a large and complete direct connected electric light plant, consisting of Ball engines, built by the Ball Engine Company, and dynamos built by the Fuller Company of Detroit, Mich.

The Shenango Valley Steel Company, New Castle, Pa., are now installing a 450 h. p. Ball engine, built by the Ball Engine Company. The engines are belted to Westinghouse generators and are used to generate power for electric cranes, electric lighting and kindred purposes.

The Sargent Co.

The heavy business so far this year, showing, in fact, an increase of something like 40 per cent. over that for the corresponding period in 1897, has made it imperative for the Sargent Company to considerably increase their capacity. To that end they have recently installed a large twenty-ton electric traveling crane, from Manning, Maxwell & Moore, in addition to the cranes now operated, and an additional saw of the latest and most improved type manufactured by the Q. & C. Company, also rearranging their receiving and shipping departments extensively. In the power house, new engines, dynamos, etc., are about to be installed. They now have a capacity of about 1,000 tons a month, which will, of course, be greatly increased by the changes now in process.

One More Big Westinghouse Generator at Niagara.

On Friday, March 18, the Niagara Falls Power Company tested the fourth great 5,000 h. p. generator placed in their station. The test was a success in every way and highly gratifying both to the power company and to the Westinghouse Electric and Manufacturing Company, the latter makers of the dynamo. This brings the capacity of the station up to 20,000 electrical horse power and is the first of the new dynamos to be installed and operated. Additional dynamos of the same design, make and size will be installed in the power house until the total output of electric current reaches 50,000 h. p.

CATALOGUES.

Catalogue of D. C. Generators and Motors of the Keystone Electric Co.

One of the handsomest and most useful catalogues issued in recent years is that of the Keystone Electric Company, Erie, Penn. This catalogue, which has embossed on its pale green cover a keystone, the emblem of this enterprising company, illustrates in detail every portion of their multipolar generators and motors. Beautiful half-tone illustrations, which give the intending purchaser an insight into the care with which their goods are manufactured, show how thoroughly each detail has been attended to. Following a very complete price list are a number of valuable diagrams showing connections of generators and motors, possible arrangements for belted units and connections of standard switchboard panels for isolated plants on the two-wire system.

Catalogue of the World Manufacturing Co.

Patterson, Gottfried & Hunter, 146-150 Centre street, New York, agents for the World Manufacturing Company, have issued a very useful catalogue and price list of the goods manufactured by this company. They include rubber belting, hose, packing and matting, detachable link belting, Hoppen's adjustable hangers, Johnson's safety collars, and Shaw's compression flange couplings.

NEW YORK NOTES.

HENRY R. WORTHINGTON, New York, has recently issued a new special catalogue devoted exclusively to power pumps adapted to be operated by electrical motors, water power, belts or any other suitable means. This catalogue places before customers a full and complete line of power pumps for all services, from which a selection can be made as readily as from the general steam pump catalogue published by the company. Believing that there is now demand for this class of machinery, the Worthington Company propose to take up its construction with the same care and thoroughness they have given their lines in steam pumps.

THOMAS A. EDISON, JR., is meeting with gratifying success in the sale of his incandescent lamp, which, though only a few months on the market, has now a sale equal to many of the lamps which have been on the market for years. He has just closed a contract with the Illinois Electric Company of 239 Madison street, Chicago, whereby they will act as his agents in Chicago. They will keep a large stock on hand.

THE UNITED CORRESPONDENCE SCHOOLS, 156 Fifth avenue, New York, are offering thorough courses of home study in all classes of engineering. Their courses in electrical engineering are thorough and practical and mechanical drawing, which is included in each course, is taught by modern methods and competent instructors.

NEW ENGLAND NOTES

PARAGON.—That the Paragon lamps are upholding their reputation for reliability is evidenced by the fact that Messrs. G. M. Angier & Company, Boston, report that business still continues good, and that they are booking new orders constantly. Their new short enclosed lamps which they will soon place upon the market for both constant potential and constant current circuits will be a radical departure from anything now in use and will embody several distinctive features likely to demand instant recognition from central stations and users of arc lamps in general.

E. PHILLIPS & SONS, South Hanover, Mass., is an old New England firm which has been identified for many years with the manufacture of pure rolled zinc plates for electrical as well as other mechanical purposes. Their large plant is equipped with the most modern and up-to-date machinery and puts them in a position to fill any order promptly for zinc, as well as making and cutting zinc to order for any purpose whatsoever. This firm solicit correspondence on the subject and will be pleased to quote prices on their product. E. Phillips & Sons' Boston office is at 107 Summer street.

MR. M. L. LIVINGSTON of the Standard Thermometer and Electric Company was in New York last week and spoke in enthusiastic terms of the success of the Upton lamps. There has been a great sale for these lamps among the mills in New England and among the sales of the high tension series arc lamp for street lighting may be mentioned a number burning on 6.8 amperes for Berlin Falls, N. H., and some for the town of Crowley, La.

WESTERN NOTES

WARREN ELECTRIC AND SPECIALTY COMPANY, of Warren, O., have just issued a very pithy and piquant circular entitled "A Roast for a Roaster," devoted to their little quarrel with the "Trust," and delivering some hot fire on the subject under discussion, namely, the real merits of their own and other incandescent lamps. It is a very lively piece of literature.

THE MICHIGAN PIPE CO., of Bay City, Mich., is working on an order of 14,685 creosoted tamarac cross ties for the Denver Consolidated Tramway Company. The latter road purchased 1,600 creosoted ties from the Michigan Pipe Company last year and after investigating the merits of creosoted ties they have placed this large order for their 1898 improvements.

ADVERTISERS' HINTS

DE VEAU & CO., 27 Rose street, New York, show another style of their telephones which are beyond the experimental stage and acknowledged a success.

THOMAS A. EDISON, JR., 96 Broadway, New York, advertises the "Edison, Jr." incandescent lamp, which he guarantees for 600 hours' life.

INSTITUTE FOR HOME STUDY OF ENGINEERING, Blackstone building, Cleveland, O., call attention to the excellence of their engineering course. They say the subscriber has all the advantages of personal attendance.

THE CHICAGO EDISON COMPANY, 139 Adams street, Chicago, Ill., offer a list of apparatus removed from their own central station to make room for larger units.

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., call attention to a special generating plant they have just shipped to the Crookston waterworks, described on another page.

THE PRATT & WHITNEY COMPANY, Hartford, Conn., in many sizes and a large variety of other tools, a description of which may be found in their catalogue "B."

C. W. HUNT COMPANY, West New Brighton, Staten Island, N. Y., mention the coal handling plant they installed for the Brooklyn Heights Railway Company. This plant consumes 25,000 tons annually and the cost of handling, including interest on the investment, is but 3½ cents per ton.

THE CROCKER-WHEELER ELECTRIC COMPANY, 39 Cortlandt street, New York, are building a new form of belt driven machine, which is described in their "ad" in this issue.

THE GENERAL ELECTRIC COMPANY advertise their 1898 styles of fan motors for alternating and direct circuits.

D. A. HEUBSCH, 31 East Rose street, New York, advise firms contemplating the presentation of souvenirs next year to correspond with them now.

THE WESTERN TELEPHONE CONSTRUCTION COMPANY, Chicago, Ill., are making another large addition to their factory to meet the demands for their "'phones, which speak for themselves, and their switchboards, which stand up."

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., have a word to say on economy and how it may be practiced by means of the Holly system of heating by exhaust steam.

THE ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, Pa., are issuing circulars describing in detail and giving results obtained from installing chloride accumulators for various purposes. They are obtainable by application.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY have installed 35 rotary transformers, aggregating 8,698 h. p.

THE B. F. STURTEVANT COMPANY, Boston, Mass., advertise ventilating fans, one style of which they illustrate.

THE CUTLER-HAMMER MANUFACTURING COMPANY, 70 West Jackson street, Chicago, have placed a large stock of their motor starting boxes with the Holtzer-Cabot Electric Company, 112 Liberty street, New York, to suit the convenience of the Eastern trade.

CARR MANUFACTURING COMPANY, 67 Beverly street, Boston, Mass., will send the Yorkshire boiler compound on trial and will not charge for it unless it gives satisfaction.

AUGUST BECKER, 34 Oliver street, Boston, Mass., continues to manufacture name plates for dynamos, engines, motors, etc., and will furnish estimates to parties interested.

THE KEYSTONE ELECTRIC COMPANY, Erie, Pa., illustrate their class "C" generator.

THE AMERICAN RHEOSTAT COMPANY, Milwaukee, Wis., say the war with Spain and their printing press controller are the chief topics of interest at present. The latter is far more certain and there is no arcing or sparking on contacts.

THE SPRINGFIELD MACHINE SCREW COMPANY, Springfield, Mass., manufacture binding posts, switchboard posts, battery screws, nuts and connectors for general and special uses.

R. THOMAS & SONS CO., East Liverpool, O., have just brought out an insulator for high voltage circuits which differs in manufacture from those already on the markets. A fuller description appears elsewhere in this issue.

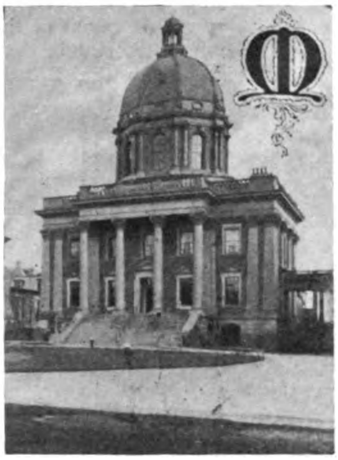
The Electrical Engineer.

Vol. XXV. MARCH 31, 1898. No. 517.

ELECTRIC LIGHTING

The Electric Lighting Plant of the Boston City Hospital.

BY H. W. WELLER, C. E.



Administration Building.

MAYOR QUINCY of Boston is nothing if not progressive, and he is also a great believer in the use of electricity, and owing in large measure to his influence and advice, the trustees of the Boston City Hospital decided about a year ago to install a complete electric installation for the Hospital. The work was placed in the hands of Mr. Cottle, chief of the Electrical Construction Division of the Public Buildings Department, and the brief description of the plant given below shows that the result is one of the finest isolated electrical installations in the country and a credit to all concerned.

In designing and carrying out the installation many difficulties were met with, especially in the wiring of the old buildings, as these were in use the whole of the time, and the greatest care was insisted upon by Dr. Rowe, the genial medical superintendent, to prevent any noise in the wards, occupied by the patients, which might cause annoyance or suffering to the sick. This necessitated the use of screws instead of nails for putting up mouldings, etc., and all cutting, sawing and fitting was done outside the buildings.

POWER PLANT.

This is located in the new power house, shown in Fig. 1, situated on the easterly side of Albany street, directly in the rear of the hospital grounds, a plan of which is shown in Fig. 2. The head house facing on Albany street is 60x40 feet and is built of red brick with marble trimmings, and was designed by City Architect Edmund M. Wheelwright.

The head house, marked 1 in Fig. 2, contains the engines and dynamos, while the boilers are installed in a boiler house 60x50 feet, marked 20 in Fig. 2, in the rear of the head house, with a tank room annexed. The stack is of brick, 100 feet in height and 5 feet in diameter inside. The boiler plant, consisting of six horizontal tubular boilers of 125 h. p. each, was installed three years ago for heating and laundry purposes. In the rear of the boiler room is a coal pocket, with a storage capacity of 3,500 tons, and the coal is unloaded direct from the vessel into this pocket by a Hunt conveyor. Hard coal is used to avoid smoke and dirt about the hospital. The steam is conveyed to the engine room through a steam main 12 inches in diameter, with suitable valves to admit live steam into the heating system when necessary.

ENGINES AND GENERATORS.

The engine room, shown in Fig. 3, is designed for six direct connected units, three of which have been installed. Each unit consists of a 17"x14" "Ideal" automatic engine, direct-connected to an 80 kilowatt 220-volt Siemens & Halske generator. The engines, which run at a speed of 250 revolutions per minute, are designed to operate with an initial steam pressure of 85 lbs. and under a back pressure of 15 lbs. to the square inch, in order to utilize the exhaust steam for heating purposes. This large back pressure is caused by the long distances that the steam has to be carried in the heating mains. When the steam is not required for this purpose it is passed through a Berryman feed water heater and then discharged into the atmosphere. Each engine is piped up with a Stratton separator, and the exhaust steam is passed through an oil separator before entering the heating system. The various steam and recording gauges and clock are mounted on a handsome gauge board of Tennessee marble.

SWITCHBOARD.

The switchboard, shown in Fig. 4, 28 feet in length, consists of 15 panels of polished black Monson slate, mounted on a handsome structure of enameled brick topped with an effective cornice. It is arranged in three sections, the central one of seven panels being used for the generators, and two end sections, each of four panels, which are the feeders. The central panel carries the switches and rheostat for controlling the motor generator, which is used for balancing the three-wire system, and also the volt and ammeters for each side of the system, also those showing the total load on the system and on the neutral bus.

Each of the three generator panels is equipped with a three-pole 500-ampere knife switch, a field switch and rheostat and an illuminated dial ammeter, flush type. Each feeder panel has mounted upon it a 500-ampere double-throw knife switch and an edgewise ammeter in each side of the system. Each feeder is provided with a double coil, double pole, circuit breaker of the Cutter Electrical and Manufacturing Company I. T. E. type. These circuit breakers are arranged so that an overload between the neutral and either outside pole will open both sides of the system, thus avoiding an excessive load on the motor generator. All safety fuses are mounted on independent slate bases

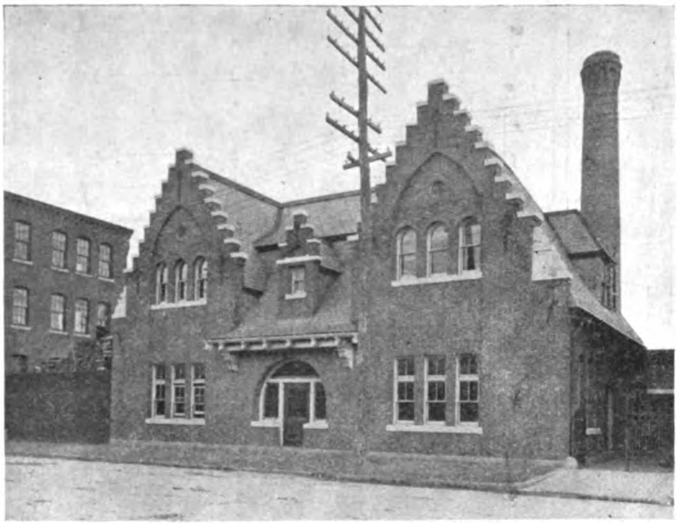


FIG. 1.—POWER HOUSE, BOSTON CITY HOSPITAL.

and installed in rear of the board, where ample space is provided for access. In case of accident to the plant all the feeders can be thrown onto the street service, for which purpose the necessary switches are provided. The volt and ammeters were supplied by the Weston Electrical Instrument Company and the knife switches are of the Murdock type, with adjustable jaws.

The switchboard, as can be seen from the figure, is of entirely novel arrangement and construction, and was designed by Mr. Hatch, the electrical engineer, the rear of this switchboard being practically a room, and has doors at either end, which can be kept locked and so prevent any tampering with the connections or wiring.

The walls of the engine and dynamo room are finished in enameled brick and the floor is of polished birch and the ceiling paneled. A heavy nickel-plated railing separates the visitors' entrance from the main floor and affords ample opportunity for viewing the plant without interference with the employees. There are also nickel-plated guard rails around the engines and generators. A telephone booth, with intercommunicating telephone, connecting with every part of the institution, is also located in the engine room.

WIRING SYSTEM.

On account of the large area covered by the Institution, aggregating over 14 acres, it was found desirable to use the three-wire

system, and this is accomplished by running the generators at 220 volts and balancing the neutral wire by means of a 5 k. w. four-pole Siemens & Halske motor generator. There is also a small auxiliary switchboard in the rear of the main switchboard by which the lights in the power house and stable adjoining can be transferred to either side of the system in case the system gets out of balance beyond the capacity of the motor generator. As a matter of fact the system is so well balanced that the motor generator takes care of the variations with ease.

DISTRIBUTION.

From the power house there are run out four sets of feeders, dividing the grounds into four sections, the south or contagious department, the easterly end of the old yard, and the medical and surgical sides of the old yard. The various buildings of the institution are connected by subways, but as some of them were already overcrowded and unfit for cables, it was decided to cross Albany street and Massachusetts avenue in special ducts. These

All cut-outs are located outside the wards. The fixture work and arrangement of the lights has received a great deal of attention, it being Dr. Rowe's aim to secure an abundance of light without any glare or inconvenience to patients. Up to the present the plant has been used principally for lighting, but it is the intention to extend the use of electricity into many of the branches of hospital service, for which it is so well adapted. There are now connected to the plant about 4,000 lights, besides a 7½ h. p. Westinghouse 4-pole motor running the refrigerating plant, and a small Crocker-Wheeler bipolar motor operating an exhaust fan. To these will be added the motors for more ventilating fans, elevators, ice cream freezers, laundry appliances, Röntgen ray apparatus, precipitators and a complete system of arc lighting for the grounds.

The entire plant was designed and installed by the electrical construction division of the Public Buildings Department of the city of Boston, H. F. Cottle, chief of division, B. B. Hatch, electrical engineer. The engines were furnished by the Boston

ducts consist of three-inch steel pipes laid in concrete. Inside the grounds the feeders are carried through the subways on special porcelain insulators bolted to the tops and sides of the subways. At the end of each feeder is a special slate distributing board controlling each circuit. From these distributing boards the mains are distributed to the various wards and buildings. These distributing boards are so arranged that should the system become unevenly balanced the branch circuit connections can be reversed to even up the load. Provision is also made for tieing together two or more feeders in case of accident. The wiring loss from switchboard to lamps is figured at five volts. The wiring of the wards and other buildings is done in mouldings, except in the new buildings, in which iron armored conduit is used.

office of W. R. Fleming & Company, agents for the Harrisburg Foundry and Machine Works, and the dynamos by the Siemens & Halske Electric Company, H. C. Spauding, Boston agent. The steam fitting for the electric plant was laid out by Engineer Howard of the City Engineering Department and executed by Ingalls & Kendricken of Boston. The foundations, piers and switchboard setting were built by A. D. Jones of Boston, and the switchboard by Wm. J. Murdock & Company of Boston. The fixtures were supplied by McKenney & Waterbury and R. Hollings of Boston, and the wires and cables by Eastern Electric Cable Company and Simplex Electrical Company.

OTHER CITY PLANTS.

Besides the above, the following smaller plants have been in-

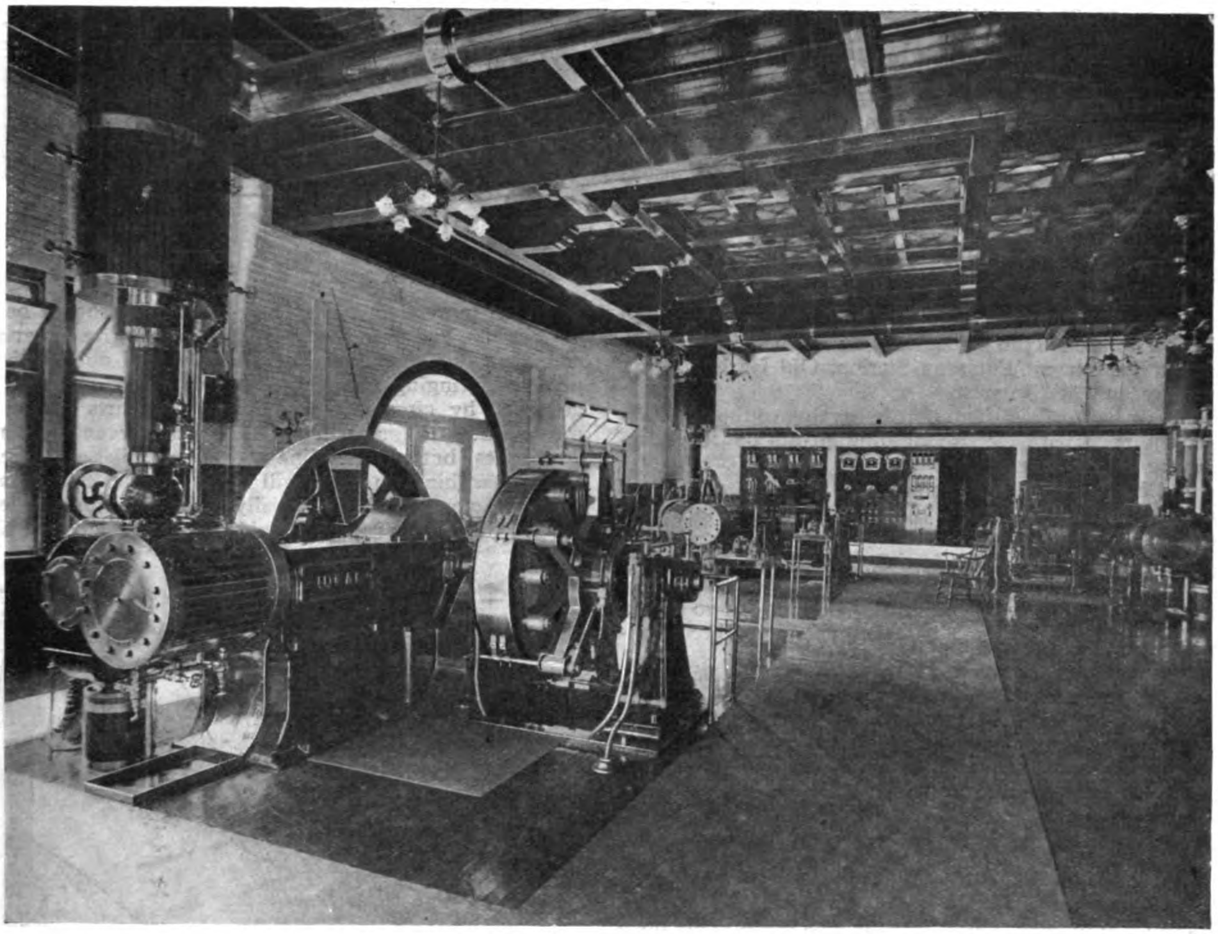

FIG. 3.—ENGINE AND DYNAMO ROOM, BOSTON CITY HOSPITAL.

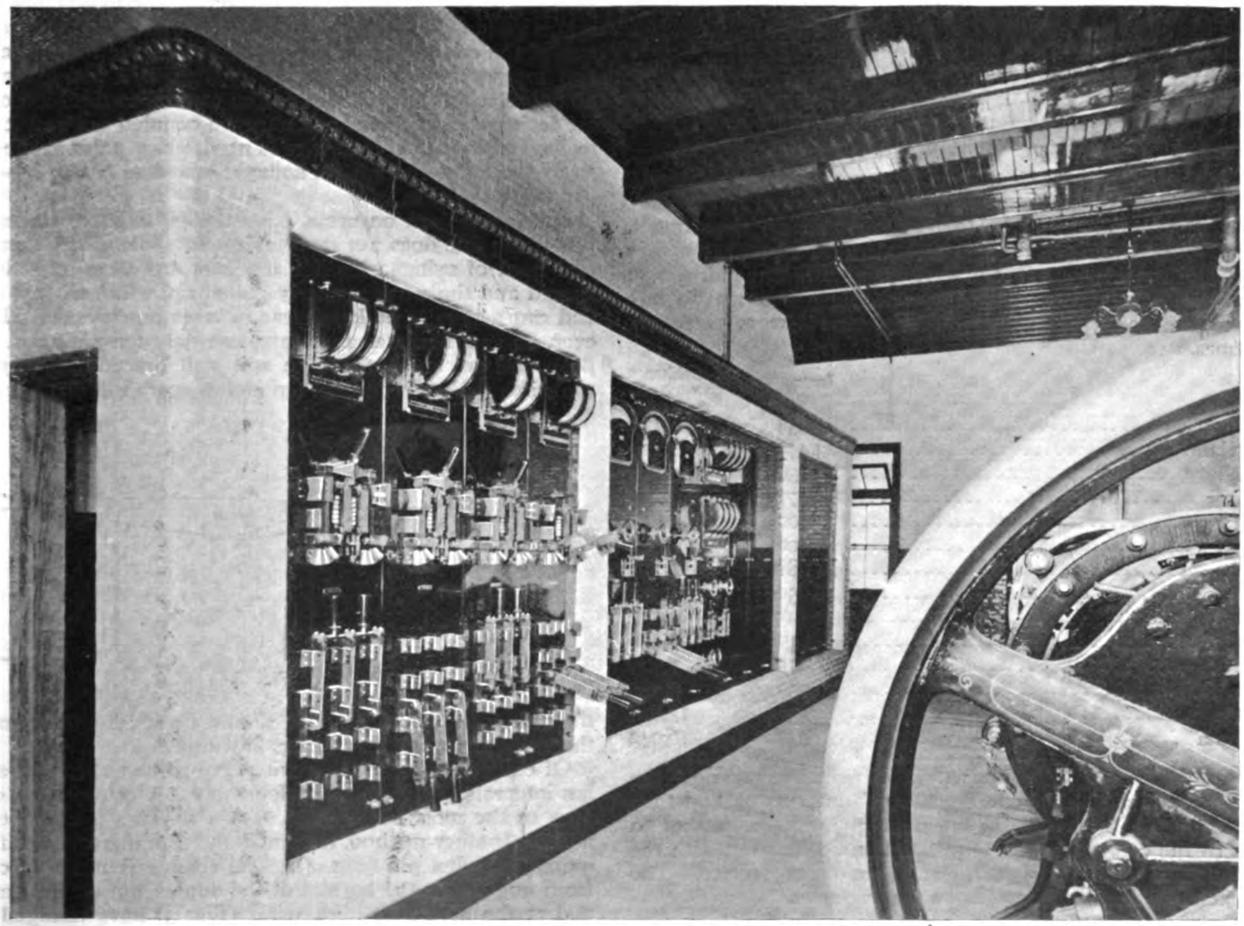

FIG. 4.—SWITCHBOARD, BOSTON CITY HOSPITAL.

stalled in the past two years by the Electrical Construction Division:

Deer Island House of Correction.—New power house designed for an ultimate capacity of 500 ... p. At present there are installed one 120 h. p. Campbell & Zell water tube boiler and one 100 h. p. McEwen engine direct connected to 75 k. w. Thomson-Ryan generator.

Chestnut Hill Pumping Station.—350 incandescents and 4 arcs. One 40 h. p. vertical marine type General Electric engine, direct connected to a 25 k. w. General Electric dynamo.

Public Buildings Department Repair Shop.—200 lights and 30 h. p. of motors. One 60 h. p. "Ideal" engine direct-connected to a 40 k. w. Thomson-Ryan generator. This is a 220-volt plant.

The Sewer Department Pumping Station, Old Harbor Point.—100 incandescents and 30 arcs.

The following harbor boats and tugs belonging to the city have also been equipped with electric lighting plants by the Electrical Construction Division:

Police and Harbor Master's tug.

Ferryboats "Gen. Hancock," "East Boston," "Winthrop," "Revere," "E. D. Kelly" and "William E. Russell."

In addition to the above the following plants were installed by contract some years ago:

Boston Public Library, 3,000 lights, consisting of two 100 k. w. and one 40 k. w. Siemens & Halske generators direct-connected to Lake Erie engines.

Long Island Alms House, 950 lights and 40 h. p. of motors, consisting of three Westinghouse engines belted to three 12 k. w. C & C generators.

Marine Park, South Boston, 200 lights and 5 h. p. motors. One Westinghouse engine direct-connected to 15 k. w. Westinghouse generator.

Fire Department Headquarters, 200 lights and connections to fire alarm generators. General Electric Marine engine and generator.

Up to the present time very little data has been obtainable regarding the cost of operation of these plants, but it is intended in the future that the Electrical Construction Division shall keep records with regard to this, and also make frequent examinations of all the plants and supervise their operation, reporting their condition to the departments to which they belong.

In conclusion, thanks are due to Mr. Cottle and also to Mr. Hatch for their courtesy in supplying the information regarding the above work.

Recent Telephone Statistics From Europe.

Mr. J. C. Monaghan, Consul at Chemnitz, Germany, sends to the State Department the following compilation of recent telephone statistics in Europe. He remarks: In no department of industry is Germany more active than in electrical appliances. The list leaves out Norway, Denmark, Finland, Great Britain, and Portugal, because these people put down no answers to the cards of inquiry; Turkey and Greece have no telephones.

Country.	Instrument.	Inhabitants to each telephone.
Sweden	42,354	115
Switzerland	23,446	129
Luxemburg	1,356	160
Germany	131,577	397
Holland	7,900	615
Belgium	9,400	682
France	31,681	1,216
Austria	18,950	1,318
Spain	10,810	1,597
Hungary	8,458	2,168
Italy	11,815	2,629
Russia	16,050	6,988
Bulgaria	243	13,616
Roumania	337	16,042

WOODSTOCK, ILL. Mr. A. B. Wager, manager of the "Woodstock Local Telephone Exchange," informs us that they have 70 miles of metallic toll line and give service second to none. In the county they have five stations competing with the Bell and nine stations where there is no other service. The local exchange has no fewer than 84 subscribers.

MR. W. CARSE writes us: I would not miss having The Engineer for anything. I think it is the best journal I get.

TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work.—III.

BY A. E. DOBBS.

COUNTRY AND TOLL LINES.

LINES more than twelve miles in length should be metallic circuits, and even the shorter lines will give better results if metallic. But sometimes the revenues will not justify the expense of stringing two wires, but this is a matter that must be governed by circumstances. There are parts of the country where grounded lines will work fairly well, even as far as a hundred miles; but a trolley line within five miles will affect them, and one within two miles will make metallic circuits necessary for satisfactory service, especially if the two run parallel. Wire used in this class of work should not be smaller than No. 12 B.

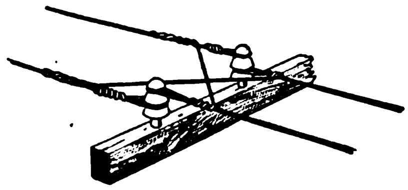

Fig. 3.

Fig. 4.

W. G. iron, or No. 12 B. & S. copper. For longer lines No. 9 iron is good up to fifty miles, though No. 12 copper is better. The size of the conductors should be such that the resistance of the two longest toll lines coupled together will not exceed 4,000 ohms. But the lines should not be worked to the limit of highest resistance, as extensions must be counted on, and it is well to have enough. If iron wire is used, place poles at the rate of 33 to the mile—though we sometimes see as few as 25—if copper, 40 to the mile.

If the wires are on arms, have the pins twelve inches apart. But if the line does not carry more than four wires, there is no real need of using arms, for brackets are cheaper, and if well spaced and the wires properly pulled up, will look just as well, and can generally be kept clear of trees much easier. If, however, an arm becomes necessary, use only ten-pin arms. If the poles are set 40 to the mile and well braced and guyed and the wires pulled tight, pins ten inches apart will do; but be sure

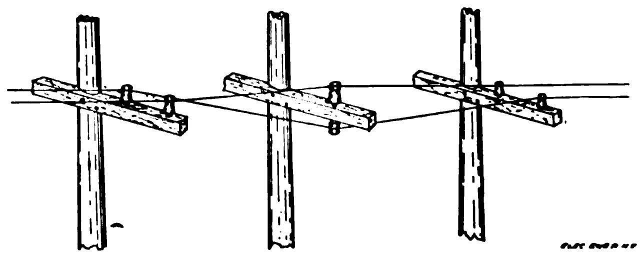

Fig. 5.

the arm is heavy enough. It should be at least three inches in thickness and a full four inches in width.

Of course, all metallic circuits have to be transposed at regular intervals. There are various ways of transposing circuits. One of the most common is shown in Fig. 3, which explains itself. Another method, known as the running transposition, requires a duplex pin (Fig. 4). The change is made by crossing from one pin to the bottom of the duplex pin on the next arm, and at the next pole both wires (Fig. 5) have changed places. This system saves making joints, but is troublesome.

The necessity for proper transposition of long metallic circuits

is well known, but just how to do it has caused a great deal of hard thinking and it sometimes keeps the best of telephone men guessing where they are at. While it is possible to map out a plan of transpositions before the line is built, still, changes are often necessary and a brief study of the principles involved will help in understanding the matter. It is pretty well understood that two or more wires running side by side for a long distance will have an effect upon each other when traversed by an alternating current and that the induced current in its neighbor has a direction opposite its own.

If we pass a current through a wire, a cross-section of which is shown in Fig. 6, and test it with a dipping needle, we find lines of force radiating from it in all directions, as shown by the dotted lines. We also see that another closed circuit nearby, at say the point A, will attract the larger number of them to one side and the nearer these two circuits are together the greater tne number of lines attracted, and that a magnet or piece of iron at A will deflect still more of them.

Turning to Fig. 7, we have shown two circuits running side by side and both in use. Supposing that both are connected to the board the same way—as they are likely to be—and that they are also connected to the same side of the battery, we have then the +, or positive side of our circuit, on the first wire, and the —, or negative, on the second. By following the direction of the arrows between the first and second circuits we find an exchange of the magnetic lines turning in the same direction as the current on the next wire between the points A and B. Now, if kept up, this would induce a condition of unbalance, and even if it did not throw in cross talk would make the lines noisy.

If now we transpose one of the circuits at B, we still find an exchange of the lines of force, but this time they are opposing, and if equal, will neutralize each other. If both circuits were transposed at B the effect would be the same as it would be from A to B, only the induction would come from opposite sides, but by transposing one circuit at B and another at C it will be seen that half the time the currents pull together and half the time oppose each other, so that if regularly transposed the effect is nil. Circuits could not be arranged to oppose one another all the time because the current is changed with the direction of the conversation, but even if it were possible to keep them opposed all the time, their effects would be to retard each other, increase the resistance of the line and throw it out of balance. Then, too, there are the induction from the earth and other electric circuits to be considered, so that even if their mutual induction were done away with or suppressed it would still be necessary to turn the circuit over, in order to present different sides to the source of the disturbance. Then there is the mutual induction between the two sides of the circuit itself, and were it not for an occasional transposition that, of itself, would upset the balance. The more the lines of force or induction can be induced to stray to its mate, however, the less there is to stray away elsewhere, and Fig. 10 shows the design of an arm intended to keep the two sides of the circuit as close together as possible, the pairs being only six inches apart, while the distance to the next circuit is fourteen inches. As the longest line is in the center, there is no need of having the wires so close, and they cannot be, on account of the pole space. But the looks of this arm will probably prevent its adoption, and, besides when wires are only six inches apart, they have to be pulled up well, and even, to keep clear of trouble.

This brings up an hypothesis held by the writer for some time, which is, that a circuit partly of iron, or steel, and partly of copper, or aluminum, will give better results than one wholly of copper. In Fig. 8, let us suppose that of the circuits 1 and 2 the two heavy lines, representing iron wire, are placed on the outside, while the two center ones are copper. Does it not seem reasonable to suppose that these iron wires would, to a certain extent, act as a shield against outside influences? Also that the magnetic quality of the iron would draw the lines of induction from its mate, instead of permitting them to stray to outside sources? It is pretty well known that a certain amount of self-induction is a good thing with which to oppose the static charge, for, while the magnetic induction travels with the current, the static charge opposes it, and by transposing at regular intervals the resistance of the circuit is kept in perfect balance.

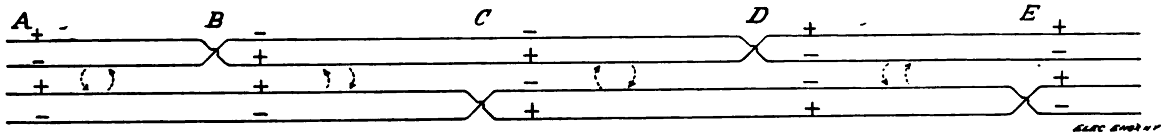

Fig. 7.

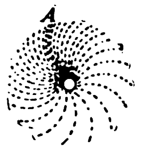

Fig. 6.

Fig. 8.

Between the two towns of Kent and Ravenna, O., there is such a line, one being No. 12 steel and the other No. 12 copper. The line is as quiet as could be desired, though, as it is only seven miles in length, it cannot be regarded as a fair test, especially as lines in that section from 30 to 50 miles in length are commonly built with No. 9 iron, or steel, and the service on most of them leaves nothing to be desired.

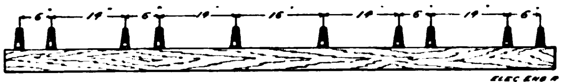

Fig. 10.

In quiet country sections, lines are transposed at intervals of a mile, but near telegraph or trolley lines this has to be increased. The only way to test it is to go on the line with a telephone and keep cutting in transpositions till the line gets quiet. In some places it may be necessary to transpose every five or six poles.

In Fig. 9 is a map of transpositions similar to that used by the American Bell Company in their long-distance work on ten-pin arms. The longer lines will not require such frequent changes as the shorter ones. Divide the line into sections of a quarter of a mile each, as shown by the letters A, B, C, D. Transpose the middle line on A and for the lines adjacent half way between, say one at C and the other at D, and, as the outside lines will probably be shorter ones, transpose twice as often, say at A, C and B, D, making these come half a mile apart. Then as each line is built, test it with a telephone and if noisy try to locate the disturbance. It may be a trolley line at one end. That being the case, cut in a few more changes at that end. When more than one office is connected to a toll line—and there generally is—bridging bells in multiple are the only kind that can be relied upon, for a 1,000-ohm bell, on account of its high resistance and high self induction, will permit of very little leak from the radily alternating currents (100 to 2,000 per second) found in telephonic conversation. In a transformer for electric lighting very little current is lost when there is no load on, because the self induction of the core gives back to the line 95 per cent. of the current put into it, and it is probable that a 1,000-ohm bell will do equally as well as ten or twelve instruments sometimes put on a line. Never use series telephones for this kind of work, as the self induction of an 80-ohm bell will increase its resistance many times beyond 80 ohms.

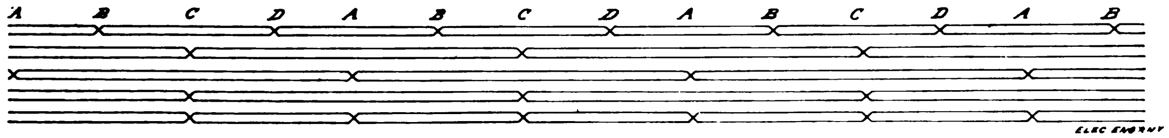

Fig. 9.

POWER TRANSMISSION

The Harnessing of the Missouri River Near Helena, Montana.

SO numerous have been the water-power installations in the far West and on so large a scale have they been inaugurated, that the East has often stood aghast at the evidence of Western enterprise and development. The contour of the land, the abundance of falls and the springing up of large industries have all been leading factors in making possible these power enterprises. This utilization has now been recognized as a necessity by the communities which vie with each other for commercial and industrial supremacy. This natural and wholesome competition has in turn brought about a development of hydraulic and electrical machinery without which the successes of the Western power plants could not have been achieved. The latest and only partially completed water power installation of the Rocky Mountain region is the one in course of construction eighteen miles from Helena, Montana. Here it has been proposed to harness the water of the Missouri river, flowing peacefully past the picturesque mountain ranges, as may be seen in Fig. 1. A timber dam, shown in Figs. 2 and 3, was constructed, giving a 27 ft. head. At one end of this dam a heavy stone embankment was built, shown in the two illustrations just mentioned, and within this structure the penstocks are imbedded as shown in Fig. 4. The penstocks enter the power house at the side facing the cliffs, and in order to accomplish this, very sharp turns had to be made, as shown in Fig. 5. The power house, which is only partially completed, is built entirely of stone and iron. A plan of the power house, showing the present installation of apparatus, as well as the penstocks, and indicating the contemplated addition is shown in Fig. 6. A vertical section of the power house, showing the penstocks entering the building, their connection to the waterwheels and the connection of these to the generators, the tail-race and other details, are shown in Fig. 7. The location of the turbines and their regulators may also be seen in Fig. 8. The hydraulic equipment consists of four pairs of 42-inch New American turbines and two single 25-inch

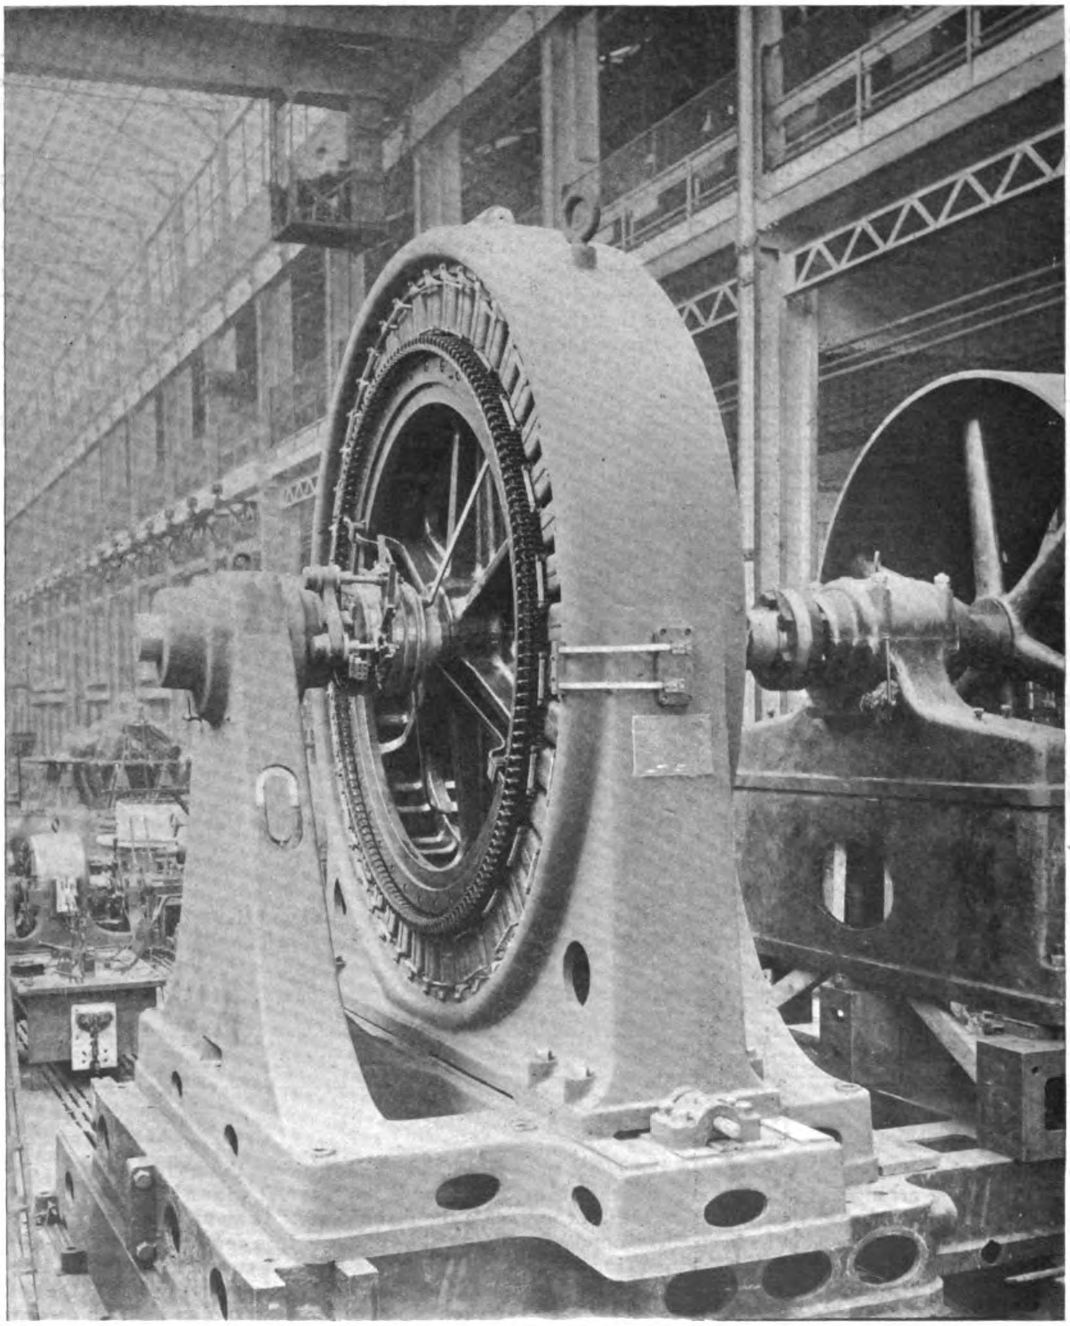

FIG. 9.—650 K. W. 2-PHASE WESTINGHOUSE GENERATOR FOR HELENA, MONTANA.

New American turbines, all constructed by the Dayton Globe Iron Works Company, of Dayton, Ohio. Each pair of the large turbines is of 1,000 h. p .capacity, and the 25-inch turbines are of 100 h. p. capacity and each drives one exciter. The entire

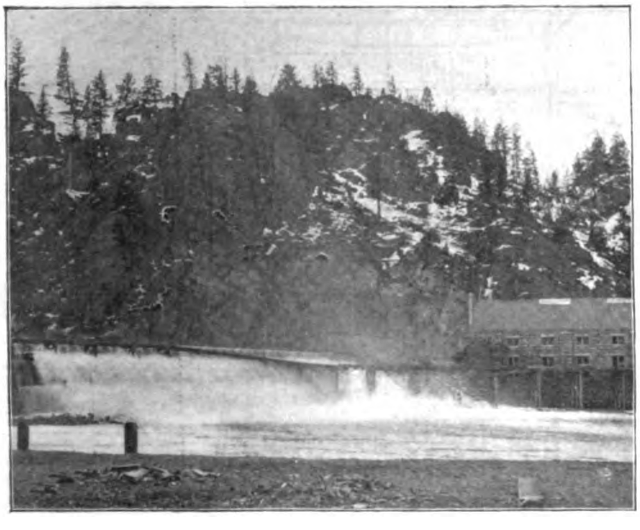

FIG. 3.—VIEW SHOWING POWER HOUSE AND OVERFLOW.

electrical equipment was installed by the Westinghouse Electric and Manufacturing Company and consists at present of four 650 kilowatt direct-connected generators shown in Fig. 9, generating current at a pressure of 500 volts. Four additional units will soon be installed. The low pressure switchboard in the power house indicated in Fig. 6 permits the running of the generators separately or in multiple. From this board the cir-

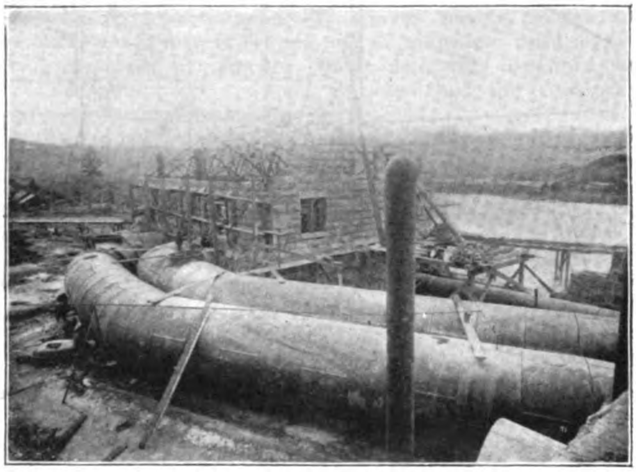

FIG. 5.—EXTERIOR OF POWER HOUSE, SHOWING PENSTOCKS ENTERING THE SAME.

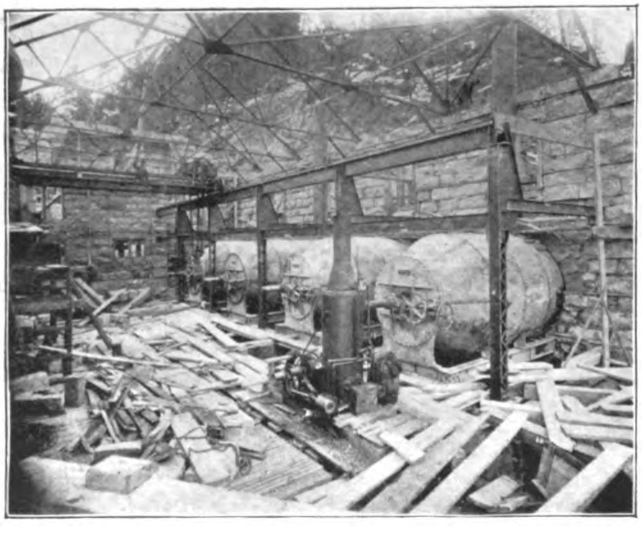

FIG. 8.—INTERIOR OF POWER HOUSE, SHOWING LOCATION OF TURBINES AND GOVERNORS.

cuits are run to the converter house about 100 feet away from the main power house. This contains eight 325 kilowatt static step-up transformers, raising to 10,000 volts, three-phase for line

transmission. There are at present four lines, consisting of No. 4 bare copper wire, supported on Imperial and Thomas insulators, running as far as East Helena, a distance of eleven miles; from there to Helena two lines are continued. A high potential switchboard at East Helena permits the running of the lines separately or in multiple, and the cutting out of any one of the lines between the power house and East Helena, in case of trouble.

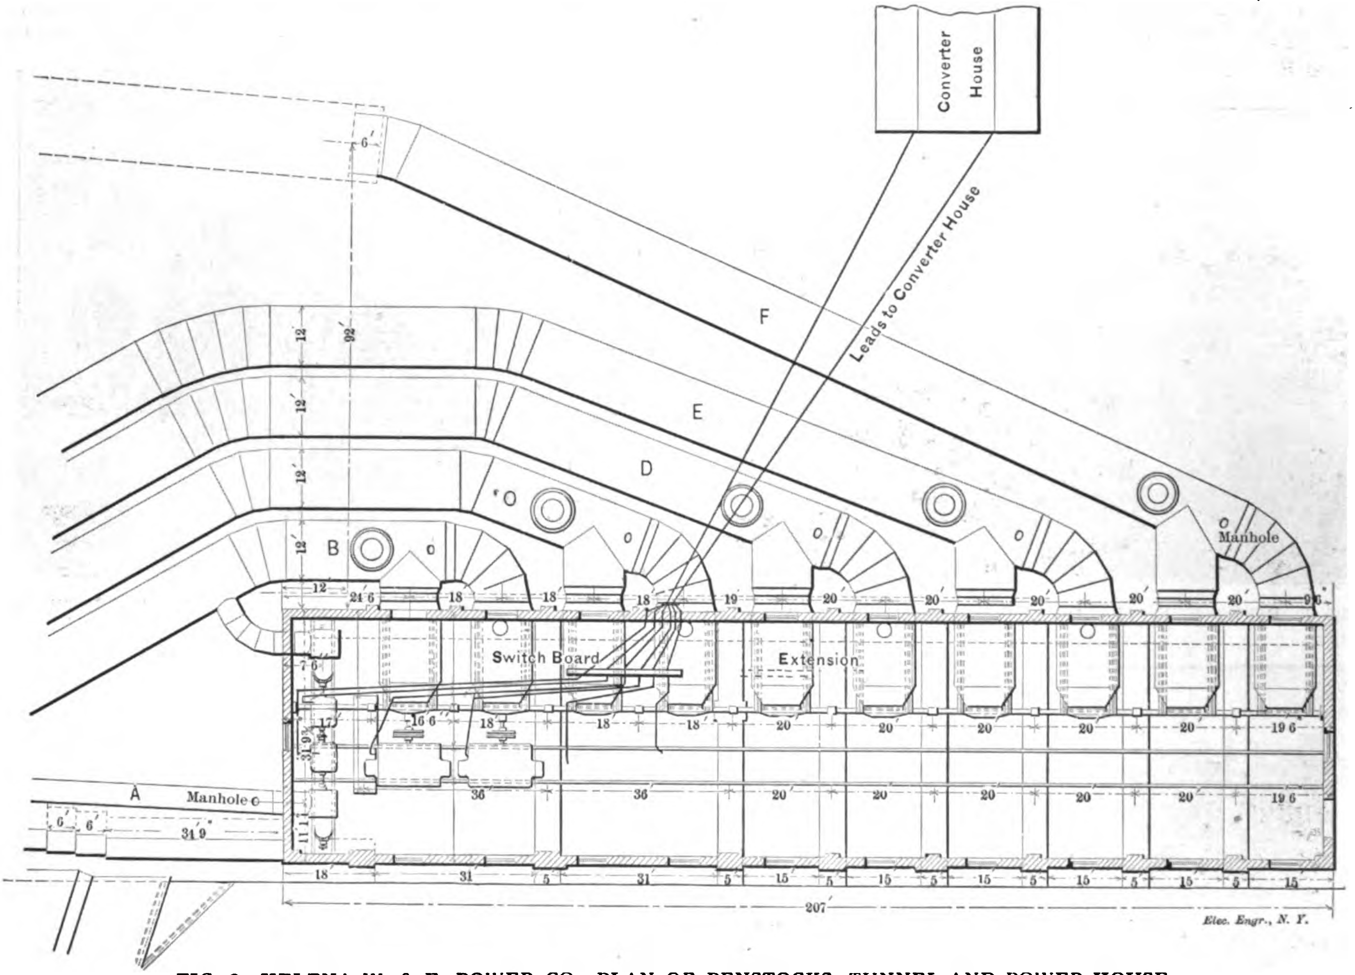

FIG. 6.—HELENA W. & E. POWER CO., PLAN OF PENSTOCKS, TUNNEL AND POWER HOUSE.

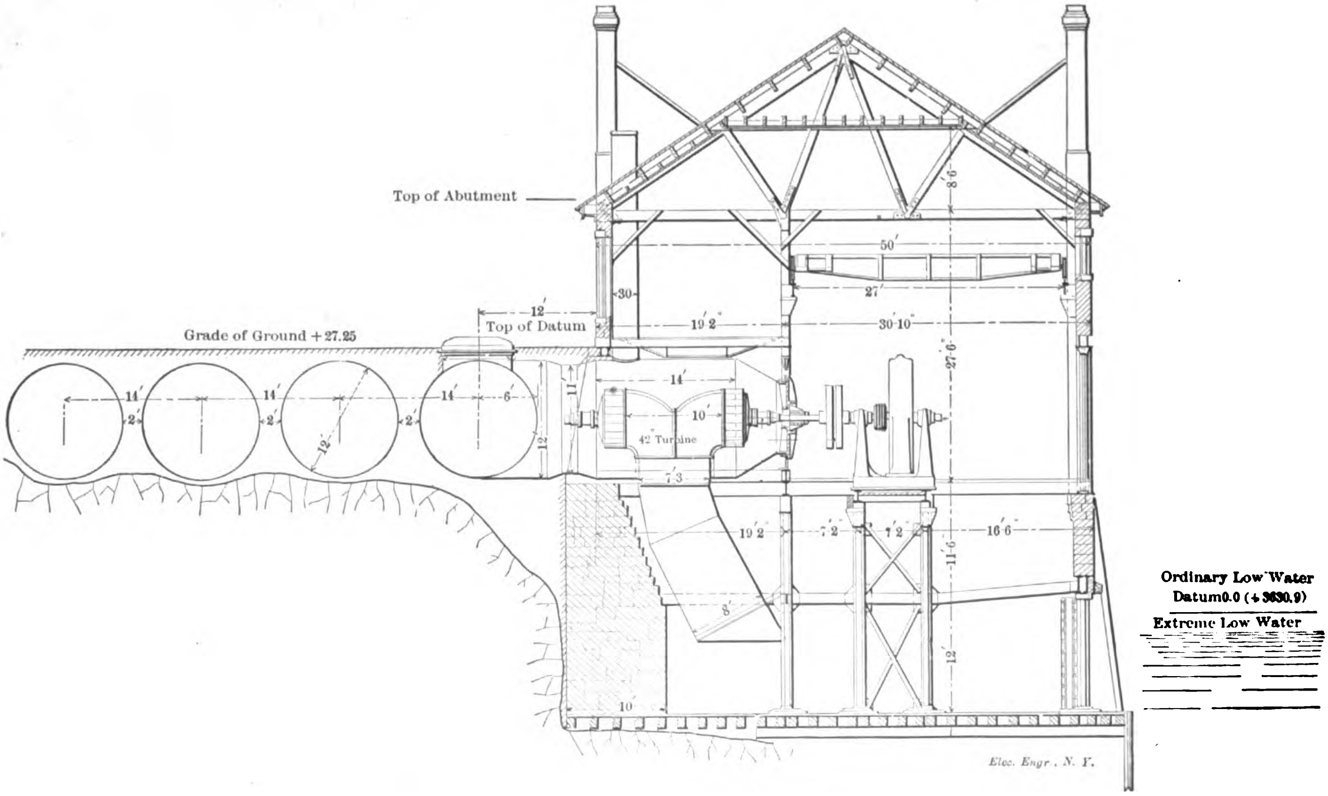

FIG. 7.—HELENA W. & E. POWER CO., CROSS SECTION OF POWER HOUSE.

Although the plant is only being installed at the present time, the company have already secured the following customers whom they will supply with current: In East Helena, the Helena and Livingston Smelting and Reduction Company, who have an equipment of two 500 h. p. and two 15 h. p. Westinghouse motors. One mile beyond tnis point the United Smelting and Refining Company use two 175 h. p., three 100 h. p., one 30 h. p. and one 20 h. p. induction motors. These operate blowers, crushers, pumps and hoists.

Two lines running to Helena supply the Helena Power and Light Company, which operates the local railway and lighting system, with power. Three 150 kilowatt transformers are installed for lighting purposes, using transmitted power directly. There are also installed three 100 kilowatt transformers, arranged in delta connections, operating two 175 kilowatt rotary

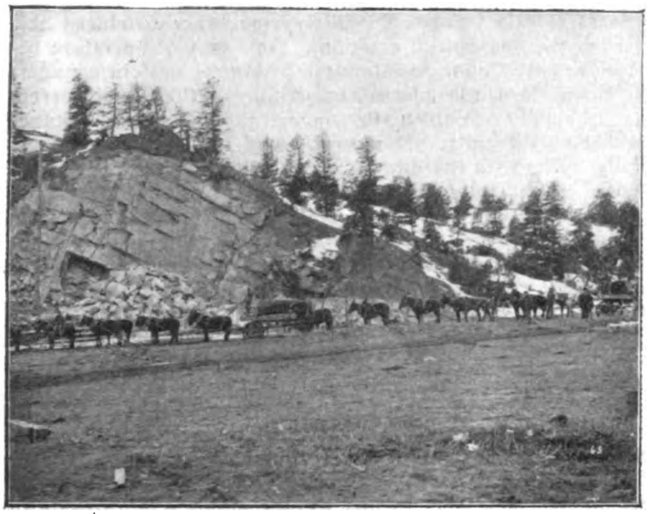

FIG. 10.—TRAIN OF MULES CONVEYING PARTS OF GENERATORS TO POWER HOUSE.

transformers for railway supply, three 50 kilowatt transformers, in delta, operating two 100 kilowatt synchronous motors, which drive arc machines for street lighting. Probably one of the transmission circuits will be used exclusively for the lighting, the other for the motor load to give good regulation.

Much engineering skill was exhibited in the design and construction of this plant, which was attended by many serious obstacles and difficulties. The apparatus had to be hauled for many miles over mountain roads, as shown in Fig. 10, and a great deal of preliminary work had to be done before the dam and power house could be erected.

Much credit for the successful carrying out of this enterprise is due to Mr. J. T. Fanning, of Minneapolis, who was the consulting hydraulic engineer; J. G. White & Company, New York, the consulting electrical engineers; Mr. B. Sewell, of Chicago, the general manager, and Mr. C. W. Whitley, the superintendent of construction. It may be stated that the heaviest stockholders in the company constructing this plant are New York financiers, who form the Smelting Company mentioned above.

Considerations Governing the Design of the Crocker-Wheeler Direct-Connected Motors.—I.

BY GANO S. DUNN, Chief Engineer.

THE speeds of electric motors are no longer a result of the necessities of design, but, owing to the progress of engineering knowledge, may be fixed at whatever value is most convenient for the intended work. Instead of the rapidly revolving armatures of the early period, requiring at least one, and often two or three, reductions of speed, by belt or gearing, we can now make, without prohibitive cost, armatures whose speeds are identical with those of the shafts they drive, and which may therefore be mounted directly upon them; which does away with the belting, countershafts, bearings, etc., upon which old-time practice had to rely.

As the power of a motor is equal to its torque, or turning effort, multiplied by the number of turns it actually makes per minute, it follows that to give an equal output, a motor which runs at two hundred revolutions will have to develop five times the turning power of one which runs at one thousand revolutions. This means it must be nearly that much larger and more expensive; and, moreover, the increased size involves increased electrical losses, which reduce the efficiency. How to get the output without too great an increase of size and accompanying cost and waste of electrical energy was the problem which the engineers of the Crocker-Wheeler Electric Company set before themselves.

These ends have been secured, first, by maintaining a high

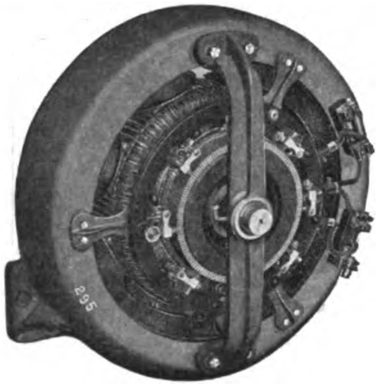

FIG. 1.—CROCKER-WHEELER SIZE 1-100 DIRECT MOTOR, WITH BEARINGS AND PLAIN FEET.

activity of material, by the employment of many poles, and the large diameter armature, which gives peripheral speed high in proportion to the revolutions per minute; second, by selecting a construction involving a minimum of labor, and third, by preferring the forms of magnetic circuit, field coils, armature core, etc., that involve not only the apparent, but the theoretical, minima of the various losses.

While the last considerations are sometimes at variance with those which secure a minimum of labor, preference in these cases has been given to efficiency, even if it involved a more expensive construction.

A gain in efficiency means a never-ceasing economy that soon pays for a moderate increase of first cost, and contributes to the excellence of the machine's performance by permitting

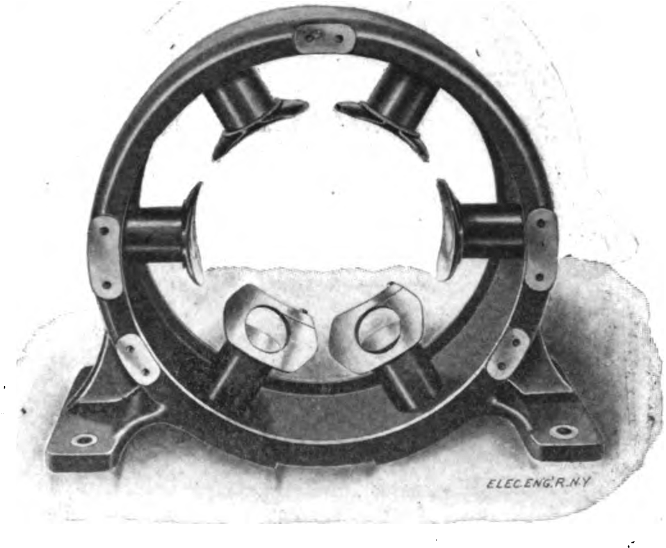

FIG. 2.—MAGNET FRAME SHOWING METHOD OF FASTENING ON THE POLE SHOES.

cooler running, greater steadiness of speed, and other desirable features.

The typical construction adopted, after careful study to secure these ends, is shown in the engraving Fig. 1.

The field is formed of a plain cast-iron ring into which are cast-welded eight, and in the two smaller sizes six, round wrought iron poles. These poles are supplied with removable shoes clamped in place by an ordinary bolt after the field coils have been slipped into position, as shown in Fig. 2. The shoes reduce the density of the magnetic flux where it enters the armature and permit thereby a long air gap which is of great value mechanically, and they also hold the coils securely. By

taking off the shoes, the coils may be interchanged for altering speed, for adapting the machine to another voltage, or for repairs.

The use of a field of many poles, each excited by a coil, greatly reduces the weight of iron in the machine, and, although in-

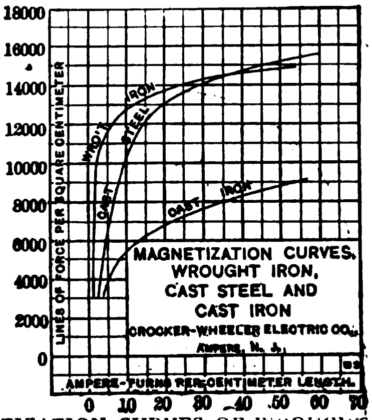

FIG. 3.—MAGNETIZATION CURVES OF WROUGHT IRON, CAST STEEL AND CAST IRON.

volving some increase in the copper and considerable additional labor, gives a motor which is easy to handle and very short in the dimension parallel to the shaft, a feature of much importance in printing press work. But these are not the only advantages, for this type is that of the maximum obtainable efficiency, as can be easily demonstrated.

Steel is so perfectly manufactured at present that it leaves little to be desired as regards magnetic permeability, but it is nevertheless excelled by wrought iron at all points except those of the higher saturations, as shown in Fig. 3. As, in machines of the low-speed type, we are compelled to work at low saturations for purposes of regulation, and to minimize the comparatively large losses, we can by using wrought iron employ a diameter of pole considerably smaller than with steel, and, as a re-

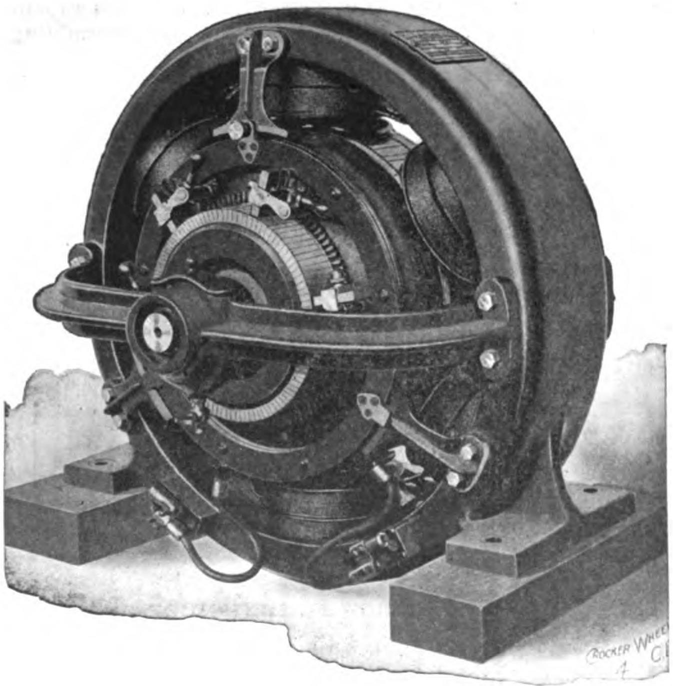

FIG. 4.—CROCKER-WHEELER, SIZE 2-100 MOTOR, FOR DIRECT CONNECTION TO MACHINE.

sult of the saving of field winding, make another gain in the machine's efficiency.

In addition to the foregoing characteristics which affect the efficiency of the type of field adopted, its form has been designed with a view to ready attachment to machinery in the most trying positions, and a shape has been selected which, while giving a pleasing appearance of solidity, will also protect the field coils by semi-inclosing them under a protecting flange that serves also as the web of a girder in strengthening the ring against collapse.

A glance at Fig. 4 will show how this shield serves to receive all sorts of attaching lugs for support of the motor wherever it is not desired to have it rest on its own feet on the floor. It will be noted that the form of field adopted is open and gives access of air to the coils, keeping them cool; and yet the fields are protected from damage by the shield.

Successful Monocyclic Power Distribution at Middletown, Ohio.

THE number of central stations using that modification of the single phase system, known as the monocyclic, by which current may be supplied to both lamps and motors at the same time from their alternating generators, has within the past two years greatly increased. This system was introduced at a time when the question of extending their area of operation began to force itself upon the attention of central station managers using either the single phase, alternating, or the direct current system of supply. With the first named the question of distance presented no difficulty, but motors could not be operated successfully by it; with the direct current system, while the motors presented no difficulty, the area of operation was limited. With the newer system it was found that both arc and incandescent lamps, as well as induction motors, could be supplied from the same alternator, the first named operating directly from the ordinary two-wire single phase circuits, the motors merely requiring a third wire to give a displaced voltage. Operation of the monocyclic system has evidently proved satisfactory, as the present installations are quite numerous.

An interesting example of the introduction of the monocyclic system into a direct current station, allowing the area of its operation to take a wide extension, exists at Middletown, O., where Mr. E. F. McKnight, the president and general manager of the Midletown Electric Light and Power Company, has recently found it necessary to increase the monocyclic capacity of his plant to meet the increased call upon his station. In addition to the arc and incandescent lighting usual in towns of the size of Middletown, certain factories under progressive managers have adopted electricity in place of steam, and the motor load on the station already far exceeds the lighting load.

The station fronts on the Miami and Erie canal, having the tracks of the M. & C. railroad immediately behind it. It is 65 feet wide and 115 feet long. Steam is supplied from two Brownell

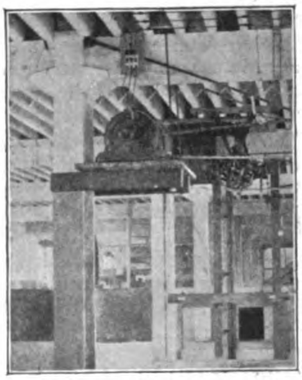

FIG. 2.—MOTOR IN ASSEMBLY ROOM OF THE MIAMI CYCLE AND MANUFACTURING CO.

& Company Dayton boilers, to one 450 h. p. compound condensing Buckeye engine and one 300 h. p. four-valve Russell condensing engine. The generating plant, shown in Fig. 1, consists of two General Electric 12-pole, 150-kilowatt, 1,040-volt, 600-revolution monocyclic generators, excited by two 1½ k. w. exciters; three 50-light Thomson-Houston series arc dynamos and one General Electric 100 h. p. 500-volt direct current generator, all driven from countershafting furnished with the necessary friction clutches.

The 500-volt machine is used exclusively to furnish direct current to several small motor plants throughout the city; the arc machines operate 112 city arc lamps. The motor load on the monocyclic machines runs up to within a short limit of their capacity. The factory of the Miami Cycle and Manufacturing Company, a little over a mile away from the station, takes 200 h. p. when its motors are running at their rated capacity, and

considerably in excess of this under usual working conditions. This company manufactures the well-known Racycle, and hundreds of these wheels are built weekly, giving employment to 600 hands. The current is received in the factory in six 40 h. p., one 20 h. p. and two 10 h. p. transformers, reducing the pressure to 115 volts. The motor circuits run from the 40 h. p. transformers, the lighting circuits from the three of smaller capacity, and all the current is measured in a recording wattmeter, connected on the primary circuit. The motor equipment consists in all of ten General Electric induction motors—three of 20 h. p. in the machine shop, driving 88 machines; one of 10 h. p. in the drill and pattern room, shown in Fig. 2, driving 29 machines; another of 10 h. p. driving the machinery in the frame department; three of 30 h. p. in the polishing room, two for the polishers and one for the 48-inch exhaust fan; one of 5 h. p. driving two plating dynamos in the plating room, and another of similar capacity operating a number of small machines in the assembling room, as well as a three-ton elevator. The incandescent lights in the factory number 750, of which, during the rush season almost all are lighted.

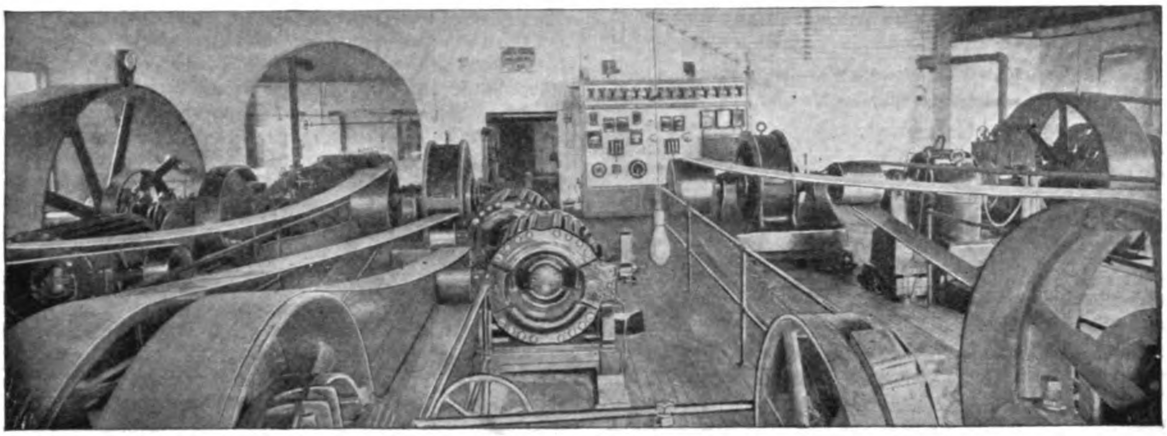

FIG. 1.—INTERIOR OF MIDDLETOWN, OHIO, STATION, G. E. MONOCYCLIC EQUIPMENT.

In addition to the cycle factory, Mr. McKnight furnishes power to the tobacco factory of the P. J. Sorg Company, in which two departments are already equipped, each with a General Electric 30 h. p. induction motor. One of these is the smoking tobacco department, on the first floor, and is belted to shafting, operating, on the three floors above, three Caldwell pickers, one cutter, two granulators and two dust machines. The second motor is on the sixth floor (Fig. 3), and is shown with the transformer and the meter to which the primaries from the station are connected. From this point secondaries are carried to motor No. 1 in the smoking tobacco department, distant about 500 feet, and the lights in the different departments being tapped off before the motor is reached. Motor No. 2 drives two 7½-inch Sturtevant fans, used to dry all the tobacco. It also operates a five-ton elevator. The capacity of the drying department is 100,000 lbs. of tobacco daily.

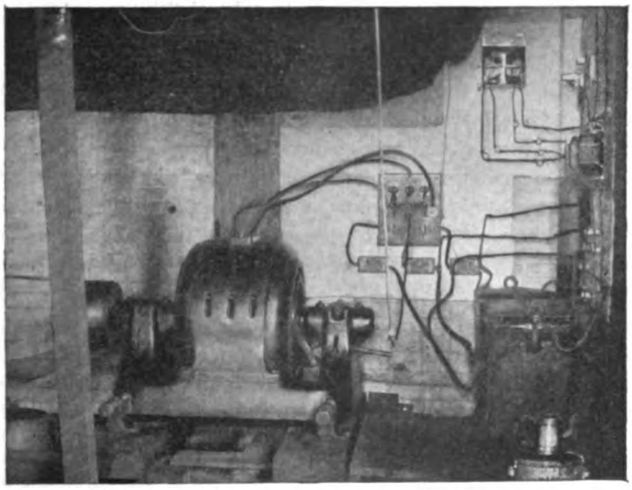

FIG. 3.—MOTOR AND TRANSFORMER IN THE FACTORY OF THE P. J. SORG CO.

The benefits of electric drive by induction motors are, perhaps, nowhere so forcibly demonstrated as in these two installations. In the cycle factory the constant speed of the machinery, the absence of vibration and the power of the motors to respond to calls reaching as high as 50 per cent. over their rated capacity, have enabled the manufacturers to give to every part of their wheels a perfect finish, as well as to greatly increase the output. In the tobacco factory the steady rate at which the tobacco passes through the dryers gives it a uniform cure. Previously, the speed being variable, the tobacco would dry in spots only, and a second handling was almost always necessary. According to the foreman, the motor "saves him lots of time."

The incandescent lights in the town already wired number 3,800; of these 750 are in the cycle factory, 100 are in the tobacco factory, 650 are in the opera house and 2,300 in other parts of the town. These lamps burn with absolutely no interference from change in the motor load; in fact, the entire motor load may be thrown on or off without in the least affecting the burning of the lamps, the presence of the motor load being usually only determined by reference to the ammeter. The monocyclic machines operate with almost perfect regulation, requiring little or no attention to maintain the constant potential at all times.

A Novel Advertising Candle.

Among the odd trade advertisements displayed at the recent Stockholm exhibition, the Lilietolmens candle played a prominent part. This candle stood no less than 127 feet high. The lower part, which was intended to represent an old Swedish candlestick, was in reality an enormous structure of bricks and mortar, in which was established a perfectly equipped candle factory, where employés worked six hours a day. The base of the candlestick covered a space 40 feet square. To come to details, the candlestick itself was 47 feet high, while the candle—a real stearine specimen—was fully 80 feet; its diameter was 8½ feet. The appearance of this extraordinary trade trophy was at once remarkable and imposing. The colossal candlestick was painted with an aluminum powder until it shone like well polished silver. At night, too, an electric searchlight of 7,000 (ordinary) candle-power cast its beams from the lofty summit of the wick over the whole of the exhibition grounds. Altogether, the cost of the monster was about $10,000.

PRINCE ALBERT LEOPOLD, of Belgium, who is now visiting this country, announces that one of his chief objects is to study our electrical work. He is 23 years of age, son of the Count of Flanders, and nephew of King Leopold, whom he is likely to succeed.

KANSAS CITY, MO.—The power plant of the Northeast Electric Railway Co. is being enlarged.

MR. H. A. HUBBELL, in renewing his subscription, says: I read The Engineer with very great interest.

Vol. XXV. NEW YORK, MARCH 31, 1898. No. 517.

Aluminum Versus Copper for Electrical Conductors.

NO one will deny that the progress of the electrical engineering industry has always been marked by a decided tendency to substitute, regardless of former usage or custom, the simpler for the complex, the cheaper for the more expensive; and the more economical for the less efficient. The rapid introduction of alternating high potential currents, induction motors, enclosed arc lamps, and the substitution of copper wire for iron in telegraphic and telephonic work have been ample proof of the above assertion. Naturally the item which represents the largest investment in any industry or a portion thereof deserves and receives the most careful consideration, as a reduction in cost or a simplification means the saving of large sums of money and less liability of accidents.

The wide distribution of aluminum in nature and the cheapening of the processes for its reduction has brought that metal prominently before the public. The electrical engineer is particularly interested in the use of aluminum for electrical conductors on account of its light weight, low cost and ability to resist corrosion. The thought to substitute it for copper soon suggested itself and arguments pro and con the use of the two metals arose and are still going on. The latest opinions on the subject are those of Capt. Alfred E. Hunt, president of the Pittsburg Reduction Company, which we published in full in our issue of February 24, 1898, and those of Messrs. H. G. Field, Alexander Dow and others who participated in a discussion of "Notes on Aluminum," a lecture delivered by Mr. Jesse M. Smith before the Detroit section of the Association of Engineering Societies. Capt. Hunt, after a thorough comparison of the properties and cost of copper and aluminum, reaches the conclusion that as to their relative cost for electrical conductors of equal conductivity, aluminum at 29 cents per pound is the more economical conductor as compared with copper at 14 cents per pound. He showed, by means of an example, in which an aluminum wire is to replace a mile of No. 10 B. & S. copper wire, that the price of the former is $22.59 against $22 72 of the latter. This is indeed a very small difference in cost and one which might easily be reversed by a slight fluctuation in the market value of the two metals. The arguments of Mr. Field are both novel and important and show that he has made a careful study of the problem. He says:

"The additional diameter of aluminum over that of copper for the same conductivity, will increase the cost of insulation for the same conductivity. The larger diameter also means more surface for the leakage of current, and the insulation resistance will be less, unless the thickness of the insulation is increased. An increased thickness of insulation means increased electrostatic capacity as well as greater cost. Moreover, it is found that if aluminum wires, of ordinary size, such as are used for electrical conductors, are bent once through an angle of 90° and back, they will break, whereas ordinary commercial copper conductors will stand from 15 to 20 of these same bendings before breaking. These are all objectionable features, and it would therefore seem doubtful whether aluminum conductors will prove merchantable. If such conductors are to be made commercially valuable it seems that the method of protection must necessarily be reduced to that of a mechanical covering, such as a braid or a series of braids treated with a bituminous composition to make it weatherproof, and also to assist in mechanical strength. This, however, will limit the use of aluminum for electrical conductors to special applications and prevent it from coming into general competition with copper."

He recommended very highly the use of aluminum fuses for switchboard work, on account of their not being altered by being traversed by a current. This was seconded by Mr. Dow, who also brought out this following important fact: In all parts of the United States a most important factor is the stress along an approximately horizontal line due to wind pressure. This stress is obviously proportional to the projected area normal to the line of stress—in other words, to the diameters of the wires strung on the pole line. The increased diameter of aluminum wire would require a much greater transverse strength of poles or much heavier bracing against wind pressure. One might expect that a pole line having aluminum conductors equal electrically to those in use by the long distance telephone company would be utterly wrecked at least once a year if erected in the lake regions, unless there were used about three times the numbers of poles, struts and stays that are customary for the existing copper conductor lines. Mr. Dow mentioned numerous practical applications of aluminum in the arts, concluding his remarks by what may be said to be a correct summing up of all the arguments brought forward and of the present situation, namely, that the new metal has been of much less value to electrical engineering than electrical engineering has been to the new metal and that this condition of affairs is likely to continue.

Insulation and Conduction.

A VERY exhaustive and highly valuable paper on the above subject was read by Prof. R. A. Fessenden before the A. I. E. E. on March 23, 1898, which embodied data accumulated by years of painstaking experimenting and reasoning. There is perhaps no question which has entered the practical side of electrical engineering as prominently as that of insulation and conduction; and few subjects which have been more frequently discussed and are less understood. A knowledge of the actual nature of conduction of currents must certainly give us a clue as to the nature of electricity itself, or perhaps a knowledge of the latter will give us information as to the process of conduction. And as no theoretical investigation can fail to produce practical results, for such is certainly the aim of every experimenter, so has Prof. Fessenden succeeded in giving to his co-workers, as the outcome of his highly scientific research, practical results which will prove of the greatest value. The paper may be divided into two parts, the first portion dealing with the theoretical side of the problem, the second, or practical portion, presenting data which to the manufacturer and designer will be highly useful and will save them trouble, time, expense and probably disaster, by not having to guess at the values of the insulation of certain materials and their degree of conduction. Prof. Fessenden's distinction between dielectric strength and ohmic resistance, which, together form the insulating power of a substance, was a fitting introduction to his theoretical, but non-mathematical portion of the subject. He then gave a brief account of the manner in which the current passes through materials, taking up in detail the questions of actual convection, which is of such

practical importance in high voltage transmission; of conduction in solids, showing that the conductitives of metals can be calculated from a formula embodying the elasticity, density and valency of the material; of conductivity in fluids, wherein he showed upon what factors this conductivity depends and which results will prove of the greatest value in electrolytic work; and of conductivity in gases, with special reference to Geissler tubes and enclosed arc lamps. Throughout this discussion Prof. Fessenden made use of striking analogies and always followed up his theoretical deductions by practical and commercial considerations. The subject of high resistance insulation, of which the author is certainly a master, was the opening wedge of what he himself terms the practical part of the discussion. He described methods of preserving the insulating qualities of rubber, and pointed out the disadvantages of glass and paraffin, and the great advantages of quartz for insulating materials in electrical instrument work. Oil he considered the best material for insulating resistance coils, and he dwelt on the importance of purity of materials used for condensers and induction coils, rather than their great ohmic resistance and dielectric strength. For making condensers, the advantage of heating the paper before using it was pointed out and supported by the results of experiments of the author and other authorities. Valuable information was presented on the construction of high frequency induction coils and the properties of oil, silk and pure cellulose, and he expressed the opinion that organic artificial rubber or non-inflammable substances which shall be elastic like rubber may be produced in the near future. Prof. Fessenden concluded his paper by discussing materials used for armature insulation and describing a couple of devices which he found useful in preventing insulation from being spoiled, such as the proper material to be used for soldering purposes. It is to be hoped that Prof. Fessenden will act on his own suggestion and at an early date supplement this highly interesting paper, which was very inadequately discussed on account of the absence of its author, by a book on insulation and conduction. It would indeed fill a long-felt want and be hailed as a valuable addition to practical electrical literature.

The Liquefaction of Air.

THE cheapening of the production of liquefied air within recent years and the remarkable results achieved therewith must have impressed everyone who has followed up the subject or has witnessed a series of experiments, with the future possibilities of liquefied air. On the same evening last week that Mr. Tripler, who has so successfully liquefied air in this country, lectured before the New York Society of Chemical Industries on the methods of liquefying air, Prof. William C. Peckham, M. A., showed some highly interesting and novel experiments with liquefied air furnished by Mr. Tripler before the Brooklyn Institue of Arts and Sciences and the Adelphi College. The very low temperature of the liquid, namely, — 346° F., enabled Prof. Peckham to freeze alcohol and mercury, to harden eggs and make rubber and all metals brittle, with the exception of aluminum. He made an ivory ball fluorescent by dipping it into the liquid, and reduced the resistance of a copper coil from 1.5 ohm to .9 ohm. The specific resistance of the liquid is said to be eight times that of water, which recalls to one's mind the following ingenious remark of Prof. Elihu Thomson some time ago: "Since ice at only 12 below freezing has a specific resistance of over 1,000 meghoms, i. e., as good as some brands of insulation, why not make the conductors hollow, lay them in a trench filled with water, pass cold brine through the pipes, use the brine for cooling houses, making ice, etc., and let the frozen water act as the insulator. A rough calculation shows that this is commercially feasible, even neglecting all sources of profit from the furnishing of the brine (i. e., if it were used only for cooling the pipes). After making all allowance for friction of fluid, cost of power, etc., the balance comes at the right end, if the line is always fully loaded."

Prof. Peckham also showed the magnetic properties of liquid oxygen and spoke of the possible use of liquefied air as a refrigerating agent. All the experiments were highly successful and can be repeated at a comparatively low cost and with very little trouble. Who can tell but that this new agent, now cheaply obtainable, besides possessing valuable properties as a refrigerating agent for cooling houses and preserving food, may give us an insight into the constitution of matter and the deep mysteries of the forces of nature?

Women in the Electrical Field.

THE various applications of electricity have for a long time past provided employment for large numbers of women, and such opportunities are growing in number. Electrical factories employ women freely; there are a great many women filling good positions in the telegraph field, and the bulk of work in telephone exchanges has always been done by girls, with much credit to all concerned. When we come to work of high responsibility, the bulk of it will probably always remain in the hands of men, but there are notable exceptions, and they appear to be decidedly on the increase. Last week our contemporary "Electricity" had the portrait of a Southern lady who is doing well as an electric light engineer and contractor, and this week we follow suit by presenting the portrait of a charming young lady in Ohio, who, at the age of twenty, is superintending a prosperous electric railway. We have recently recorded other instances, one of a lady in the South engaged in railway work, and one of a lady in New York State who makes a business of contract wiring. A few weeks ago a note was made of the employment of a married woman as "motorneer" on a New Jersey electric road, but we believe she is not now filling the position, chiefly because of objections on the part of her male companions on the road and of her husband. Still there are many lines of usefulness open, a fact of which we were reminded also this week in noting that the technical drawings attached to a patent were made by a woman who has long been doing in that field some of the best work possible.

The Correspondence School.

OUR announcement last week with regard to The Electrical Engineer Institute of Correspondence Instruction has, we find, excited widespread interest, as might have been expected. In these days every effort to add to the number of educational means and forces attracts attention; and while the standard of ultimate training is ever raised higher, the degree to which knowledge and culture become attainable is ever broadened. It is particularly in technical branches that the needs have been felt, and in a field of such sudden development as electricity the wants of the newcomers are as insistent as they are varied. The best comment on the value of the work to which this journal is now lending its support is to be found in the response of those whose necessities it is proposed to meet. If we had any doubts on that score, they are removed, and we are glad to believe that The Electrical Engineer is fostering a highly useful agency in the new scheme. The reading pages of the paper will have little to say hereafter about the school, it being a wholly distinct and separate institution, but we desire to inform those who do not receive the literature of the school at once, in response to their requests, that copies of the documents will reach them as soon as a further supply can be printed. We must beg to refer inquirers and applicants to the school itself, or to its advertisements, for such information as they may be desirous of obtaining.

Sudden Death of Mr. Nelson W. Perry.

WE regret to learn, just as the forms close, of the sad death of Mr. Nelson W. Perry, the well-known electrical journalist. He was experimenting, it appears, on Saturday last, in lighting, at his house in Brooklyn, and by mistake, in the dark, took up, and drank from, a cup containing bichromate of potash, instead of one of water. He sent out at once for doctors, but they were unable to pull him through, and he died on Sunday night. Mr. Perry was a son of Judge Perry, of the Supreme Court, of Ohio, a graduate of Columbia, and a man of great ability. He was an active member and officer of the American Institute of Electrical Engineers. He leaves a widow and three children.

MUNICIPAL AFFAIRS

Municipal Electric Lighting.[1]—VI.

BY PROF. JOHN R. COMMONS.

APPLICATION OF DEPRECIATION FUNDS.

THE above estimates for depreciation are of course not actually written off by the municipal officials, but are calculations made by Mr. Parsons. In fact it is almost invariably the rule that the managers of municipal plants make no allowance whatever for depreciation.

It is not to their discredit, however, as compared with private corporations. Mr. Foster says: "It is but fair to say that in a comparison of municipal with private plants, the charging for depreciation and interest, is fully as much neglected by one as by the other; less than one in ten of either paying any attention whatever to these items." The report of the Massachusetts Gas and Electric Light Commissioners shows that in 1896 the electric light companies of that State set aside for depreciation funds $446,662.89, which was 3 per cent. of the total assets of the companies. Two hundred and fifty thousand dollars of this was credited to one company, the Boston Electric. Of the eighty-three companies in the State, one thirty-three made an account of depreciation, and, apart from the Boston Electric, whose depreciation was 8 per cent. of its assets and 15 per cent. of its capital stock, and the Edison of Boston, whose depreciation was 2 8-10 per cent. of the capital stock, and 2 3-10 per cent. of the assets, the depreciation entered by the other thirty-one companies was less than one-half of 1 per cent. The Edison Illuminating Company of New York in 1894 for the first time carried a part of its profits to a depreciation fund, and the directors, remarking upon the novelty of the transaction, wrote: "This conservative course will no doubt commend itself to the stockholders."

As to these private companies, it does not follow, because they carry a depreciation fund, that they have actually written any depreciation off from their capital investment. The proper method would be to deduct depreciation from the capital and to add new construction, giving at the end of each year a new net capital investment, but as the companies are usually stocked and bonded at a high figure, it is of some advantage to them to keep adding new construction to their construction accounts without deducting depreciation, thus actually inflating their apparent investments. The depreciation fund which they carry is therefore merely a part of a larger policy which conservative corporations adopt, namely, the accumulation of a surplus in the treasury of the company rather than the distribution of this surplus in dividends to stockholders. This surplus may be invested in stocks and bonds of its own, or of other companies, or may appear in several different forms, such as profit and loss, depreciation fund, reserve fund, or insurance fund. By a policy of this kind the stockholders, though getting smaller dividends for the time, are nevertheless, while keeping up their plant by repairs, renewals, new construction, and operating expenses, increasing the market value of their stock, and their capacity to buy up and absorb other corporations and competitors, besides also giving added security to their bonds, and increasing the company's ability to borrow money at low rates.

Now, these conditions are wholly absent from a municipal corporation owning and operating an electrical plant. The taxpayers do not hold negotiable stock in the plant, which they may wish to hypothecate and so desire to have it backed by the possession of a reserve fund. They do not want the electrical plant to accumulate a surplus to be invested in securities against either future extensions of the business or replacements of worn-out machinery. The city is not a business corporation empowered to re-invest the earnings of its stockholders, the taxpayers; but the latter want to re-invest their own money in their own way and under their own individual control. Hence they want their dividends at once for private purposes in the form of low taxes or low charges. This leaves no room for the accumulation of a reserve by whatever name it may be known. If the municipality is to take account of the depreciation at all it is not in the form of a surplus fund on which the future taxpayers may draw in case of exigency, but it is in the form of such a provision for the distribution of depreciation over successive years that the taxpayers of no single year will be unduly oppressed. This will appear more clearly if we consider the true nature of the depreciation.

EXTENT OF DEPRECIATION.

There are three kinds of depreciation to be taken into account —depreciation by use, depreciation by competitive improvements and depreciation by replacements.

Depreciation by use is the actual wear and tear upon machinery, the burning out of armatures, the breaking of globes and lamps, the crippling of tools, the weathering of paint, poles, lines and so on. This kind of depreciation is entirely covered by the item of repairs and renewals, properly chargeable to operating expenses, and is so entered by every honest official. It does not need additional provision under fixed charges. However, it eventually contributes to the third form of depreciation, that of replacement.

Depreciation by competitive improvements consists in the lower cost of operation and maintenance which new inventions and improved machinery have introduced since the installation of the plant. It is asserted now that the saving effected in arc lighting by substituting 100 and 125 arc dynamos for the 35 and 50 arc dynamos of the earlier days is 40 per cent. of the maintenance. In the direct-current service the large units effect a saving of 20 per cent., which is increased even to 50 per cent. by being directly connected to the shaft of the engine instead of being belted. In alternating currents the difference is less, but the lower speed, lower temperature and ability to run continuously make their adoption a commercial gain. Such striking improvements in electrical machinery within ten years render the plants of that length of service quite antiquated. Were the business a competitive one and readily open to new companies there could be no question that the private plants installed a few years ago would all now be bankrupt, in so far as they have not met the improvements of the day by substituting new machinery. But having a monopoly and being able to charge the prices of a decade ago they are protected in the use of antiquated machinery and need introduce the new appliances only with the extension of new business. This kind of depreciation in a competitive business would be corrected by writing off depreciation from the capitalization, and the market value of the stock would sink gradually until bankruptcy or reconstruction ended it. But in a monopolistic business the power to keep up old rates is the power to withstand the pressure of competitive improvements. This is the very reason why in such a business municipal ownership, or at least municipal regulation of charges is demanded. And if the municipality, in case of ownership, did not choose to put in the new machinery before the old should wear out, the consumers certainly would be no worse off than with private monopoly. Certain it is that the charges by private companies for either public or private lighting have not fallen in proportion to the great improvements in production even where the companies have been enterprising enough to replace the old by the new machine. It is this kind of depreciation by competitive improvements that experts have in mind when they place depreciation at 10 per cent. For certainly the life of a dynamo is equal to the life of an engine if it be equally well cared for and if repairs are made as needed, and the depreciation by use in either case would not shorten the life of the apparatus to less than thirty or forty years. This kind of depreciation is not to be computed as a fixed charge, since it already shows itself in operating expenses by high cost of fuel, labor, repairs, etc.

Depreciation by replacement occurs as a result of the other two forms of depreciation, when old machinery through wear and tear and in view of improvements is sold out and new is put in its place. When this shall occur depends upon the policy of the management. A few enterprising private companies have already begun to reconstruct their electrical plants, not because of depreciation by use nor by competition, but because the saving with new improvements more than covers profits on the cost of reconstruction. As a rule, however, in a monopolistic business of this kind replacement does not occur until depreciation by use had advanced so far that repairs and renewal of minor parts fail to maintain the efficiency of the plant. Whether in the case of a city or a company, the financial circumstances of the owners determine how long they shall wait before selling the old and substituting the new. On this basis it will be safe on the whole to estimate that the entire depreciable part of the plant, including steam and electric plants, poles, lines, meters, transformers, lamps, should be replaced every twenty to thirty years. This

[1]Municipal Affairs, Dec. 1897. A Reply to R. R. Bowker. See Elec. Engr.

replacement would not occur all at once, but would be distributed throughout the period.

Municipal Ownership At Le Roy, N. Y.

The annual report of the Board of Water and Light Commissioners of this village, which has just been made, reveals a startling condition of affairs, and it is at once apparent that as a result taxes the coming year will be greatly in excess of what they have been. Before the water works were put in the taxpayers were told by the water commissioners that for the sum of one and one-quarter mills, added to the present rate of taxation, which was then $6.50 per $1,000 assessment that they would furnish a pumping station, help, coal, repairs, interest on bonds and all expenses attached to the water system. When it came to voting on a municipal lighting system the taxpayers were again made to believe that a municipal plant could be operated at a saving. At that time the village had an offer from the Hydraulic Company to light the streets for $2,000 per year for a term of five years. Now, by the report just issued, it is shown that the money needed to operate the municipal plant for the coming year with the same number of lights is $4,938. It had also been argued that the gas plant would be a profitable investment at $20,000, for the village to own. The report shows that to operate the plant $1,440 will be needed for coal, and the estimated receipts for the sale of gas only amount to $1,500. This would only leave $60 with which to pay the interest on $20,000, and also the help needed to run the plant, besides necessary repairs.—Rochester, N. Y., Advertiser.

ROENTGEN RAYS

J. J. Thomson's Theory of Röntgen Rays.

AN important contribution to this subject is made by J. J. Thomson. He bases his theory upon the known laws concerning the generation of an electro-magnetic field by a moving electrified particle. Such a particle "is surrounded by a magnetic field, the lines of magnetic force being (as in the case of an ordinary current) circles having the line of motion of the particle for axis. If the particle be suddenly stopped, there will, in consequence of electromagnetic induction, be no instantaneous change in the magnetic field; the induction gives rise to a magnetic field, which for a moment compensates for that destroyed by the stopping of the particle. The new field thus introduced is not, however, in equilibrium, but moves off through the dielectric as an electric pulse." The electrified particle in question is the "cathode ray;" the pulse generated by its sudden stoppage is the Röntgen ray. The author calculates the magnetic force and electric intensity carried by the pulse to any point in the dielectric, and arrives at some most suggestive and, indeed, corroborative conclusions. When the velocity of the particle approaches that of light, two pulses are started when it is stopped. One of these is a thin plane sheet whose thickness is equal to the diameter of the charged particle; this pulse is propagated in a direction in which the particle was moving; there is no corresponding wave propagated backward. The other is a spherical pulse spreading outward in all directions, whose thickness is again equal to the diameter of the charged particle, and thus, if this particle is of molecular dimensions or smaller, its thickness is very small compared with the wavelength of ordinary light. In vacuum tubes, the particles, whatever they are, are stopped by the walls of the tube, possibly after rebounding several times. The greater their velocity, and the smaller their mass, the more instantaneous will be the stoppage, the thinner and stronger will be the pulse, and the less of it will be absorbed in its passage through substances. The Röntgen rays are therefore not waves, but a rattle of irregular but intense impulses, something like bad musketry.—Phil. Mag., February, 1898.

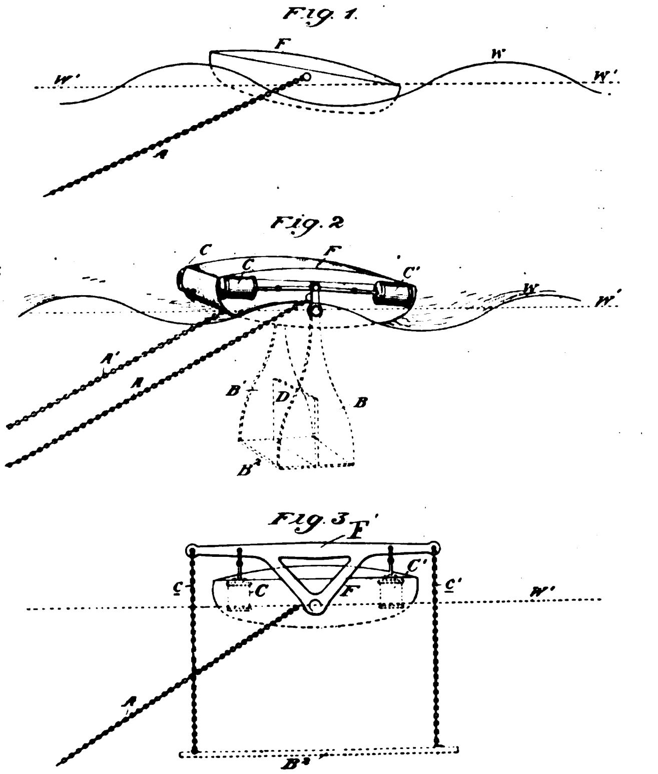
MR. PAUL H. JAEHNIG writes us: "I renew my subscription to your most valuable journal. I always find your paper right up to date, and a most valuable paper for a practical man; and would not be without it."

MECHANICAL

The Bunnell "Wave Motor."

A FORM of wave power apparatus which is fundamentally different from any of the several hundred existing types of motors in that line and which appears to present decided advantages in many important respects has recently been patented by Mr. Jesse H. Bunnell, the well known electrical manufacturer.

No piers, docks or permanent structures are employed excepting a stout anchorage capable of holding against any gale. Secured to this anchorage in the usual way of anchor fastening, by sufficient length of chain, is a strong seaworthy barge, boat or float. The anchor chains are, however, fastened to the barge or boat-hull at a point about amidship or a little forward of the same, so that the force of the waves will tend to give the utmost "pitching" or fore and aft rocking motion to the vessel, alternately lifting the bow and stern high in the air and dropping each in turn as the waves rise and fall—first under the bow and



Figs. 1, 2, and 3.—SHOWING THE PRINCIPLE AND INTERIOR MECHANISM OF BUNNELL'S WAVE MOTOR AND ITS APPLICATION.

then under the stern—as shown in Fig. 1 where F is the float and A one of the anchor chains, there being one on each side; W being waves and W^1 their mean level.

To convert the enormous force exerted by the rocking motion so produced into working effect, a great paddle is hung from the sides of the hull amidship to a depth sufficient to place it, the paddle, in still water below the wave motion. To the upper end of the paddle arms above the pivot center of motion are attached jointed piston rods connected with force pumps, as shown in Fig. 2, where F represents the float, B, B^1, two vertical lever arms pivotally secured on trunnions at opposite sides of the float, their lower and longer arms being broadened to support a horizontal bottom or surface B^2 and a vertical paddle D, the upper or short arms being connected by jointed piston rods, as shown, to the piston heads of four pump cylinders, C C C^1 C^1, operatively connected by properly constructed pumping tubes on the inside of the float with any form of motive device.

It will be evident that the violent and almost resistless rocking of the hull acting through the pump cylinders against the

nearly stationary paddle located in the still water must naturally exert a great power in forcing water through the pumps and into a suitable pressure chamber, from which it may easily be led to a Pelton wheel operatively connected to a dynamo, all contained under the deck of the floating vessel F; current so produced could be carried ashore by cable. A lift and fall of twenty tons through two feet, five times per minute, would amount to about 25 h. p. and for large work the vessel could easily be of several hundred tons displacement.

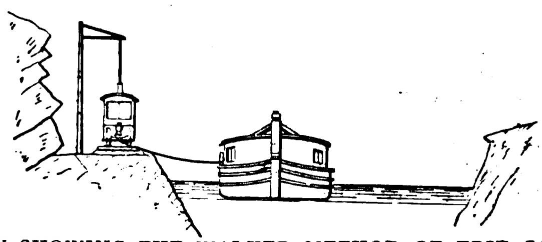
The absence of any necessity for stone work, piers, steel trusses and all the usual features of stationary structures would make the device comparatively inexpensive. The floats or hulls could be built in any ship yard, towed to and anchored wherever wanted, and removed to other points at pleasure: they could be of steel and adapted to withstand the most terrific storms.

Another form of this device which would be capable of application to light ships, stationary dock floats, and possibly even on sailing vessels for use in pumping is illustrated in Fig. 3. A submerged platform, B^4, is pivotally hung from the center of a float or hull F by chains c c^1 and two trusses F^1 F^1 and trunnions so that its entire body is below all wave motion and its upper surface in a parallel plane with the water level above, C C^1 being pump cylinders as before.

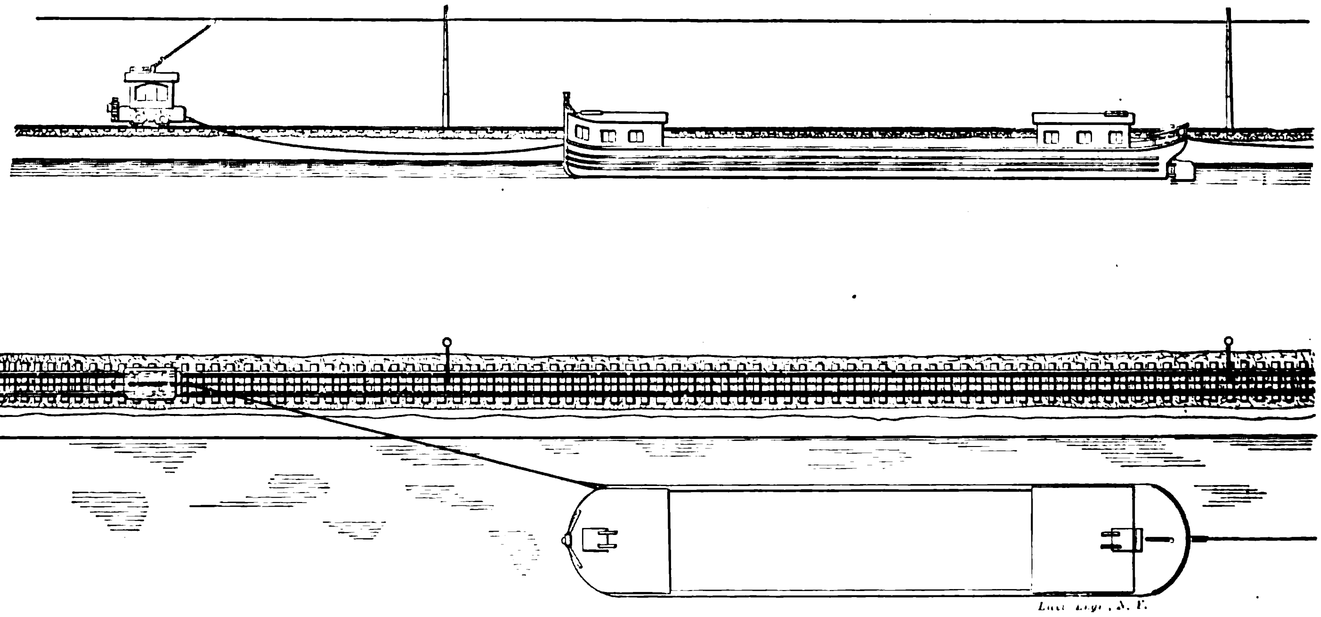
All the apparatus for the operation of this form could be carried aboard a sailing vessel, requiring simply the lowering from davits and submerging the suspended platform which would connect with pumps on board by chains. It is not unreasonable to believe that all the heat, light and power which would be required on board a light ship could be readily produced by this means due to the constant rocking motion of the ship.

Walker Plan For Electrical Operation of Erie Canal.

AMONG those who have recently addressed themselves to the problem of operating the Erie Canal and other canals electrically, with economy and efficiency, is Prof. S. H. Short, on behalf of the Walker Manufacturing Company, of Cleveland. The proposed experiments are about to begin at Tonawanda, and we have been favored by Mr. Frank W. Hawley with the plan to be used, and it will be powerful enough to haul a tow of five boats, each of 250 tons burden, at the rate authorized on the canal, namely, not exceeding six or eight miles an hour at the most, in order that the wash from the boats shall not undermine the banks. The drawings herewith are so simple as to be self explanatory, but the details of providing for adjustment to curves, strains, etc., are not given out for the present. Prof. Short believes in the great cheapness and economy of this method, having long had the subject under study, and he considers that it has as many incidental advantages as some other methods have objections, even if they may claim greater novelty.



VIEW SHOWING THE WALKER METHOD OF ERIE CANAL BOAT PROPULSION.



WALKER METHOD OF ERIE CANAL BOAT PROPULSION.

that is to be tried. In the present case, it is the intention to haul a tow of boats by means of a locomotive on a track paralleling the canal, the track being placed in actual operation on the berme bank of the canal. A mining type of locomotive is

Important Electric Railroad for Michigan.

An organized company formed with George E. Taylor, of Flint, Genesee county; J. E. Sawyer, Hon. S. W. Smith, of Pontiac, Oakland county, and other parties, recently obtained franchise and will build an electric railway from Pontiac to Flint, covering one of the most richly fertilized and industrial territories of the State of Michigan for a distance of about forty miles northwest of Pontiac. The route of this proposed road has been already carefully surveyed and from Pontiac will run through and have stations at Drayton Plains, Waterford, Clarkston, Ortonville, Goodrich, Atlas, Grand, Blanc, to Flint. All these small towns at the present time are without facilities of transportation, and an electric railway will undoubtedly find ample and profitable traffic both in the passenger and freight line.

The location of this road will be in the hearts of Oakland and Genesee counties, which are thickly settled with a number of small towns and villages, with flourishing trade and abundant farming produce. The road will be solidly built, and 70-lb. T. rails used, so that heavy traffic can be carried on it equal to any steam roads. The best electric apparatus will be used, and two power houses will be built, respectively located one in Pontiac the other in Flint. Interested parties are now negotiating with Eastern capitalists and the company contemplate to start the grading of the line within a few weeks. For particulars and

more ample information, Joseph E. Sawyer, Esq., attorney at law, Crofoot building, Pontiac, Mich., will be glad to be addressed.

Miss Anna E. Mitchener, Superintendent of the Tuscarawas Electric Railroad.

THE electrical engineering profession would indeed be narrow if it did not offer to the ambitious and courageous woman an opportunity to give evidence of her proverbial executive ability and foresight. Of late years thousands of women have found employment in the various departments of electrical manufacturing concerns, as private secretaries and in other electrical work congenial to their tastes. But never before have we had occasion to record in our pages the remarkable fact that a young woman is actually superintending an electric railroad. The Tuscarawas Railroad Company, of Ohio, which owns and operates an interurban road, ten miles in length, connecting the twin cities of Uhrichsville and Dennison with New Philadelphia, is a well equipped, thoroughly modern line, with power house, car barn and office, located about half way between Uhrichsville and New Philadelphia. When the road was formally opened in September, 1896, Miss Mitchener was given a place in the office, where, under her father's careful direction, she became acquainted with the inner workings of the great problems involved in street railway work. Miss Mitchener has held her present position, as superintendent, since last November and in this brief period has met with marked success, which is largely due to the fact that the employés of the road are all carefully selected and thoroughly trustworthy men. She has at all times endeavored to meet them on a friendly footing and to make them feel that they, too, had an interest in the welfare of the road. In this way she has been able to maintain perfect order and union among quite a large force of men who might otherwise have resented being superintended by a young girl of twenty. It may be stated that the company was organized at Columbus, O., with an authorized capital stock of $150,000, and its officers are: President, Will Christy; vice-president, C. E. Mitchener; secretary, and treasurer, C. H. Howland.

LETTERS TO THE EDITOR

The Jungfrau Road.

We notice an article in your issue of February 24, describing the railway now under construction up the Jungfrau. A list is given at the end of the various firms who have supplied the different parts of the plant, but we notice that no mention is made of the fact that we have supplied the whole of the electrical equipment of the locomotives there illustrated. We would be glad if you would kindly make this fact known in a forthcoming number. The omission seems to us the more unfair, since it was at our suggestion that three-phase motors have been adopted as the actual driving power on the locomotives. It may be true, as the writer of the article states, that "Electricians have, almost without exception, recommended alternating currents as working most economically for long distances." But they never thought of using them directly on the locomotive itself until on a small scale in the Lugano tramway, and later on the Gorner Grat mountain railway, we showed it to be practically possible. The contract for the Gorner Grat railway, for which we have supplied the whole of the electrical equipment, was given more than a year before it was decided to adopt the same system on the Jungfrau line, and the successful trial trips which were made on it, as noted in your issue of December 23 last, proved that we were justified in our proposal to employ three-phase currents throughout.

BROWN, BOVERI & CO.

Baden, Switzerland, March 9.

"Blind Leading the Blind."

THERE is perhaps no subject of greater interest and usefulness to the electrical engineer of to-day than the design of dynamo-electric machinery, and, though many books and articles have been written on the theory, design and construction of dynamos and motors, it still appears that very few writers have "filled the long-felt want" of a practical treatise on the subject. Who will deny, for instance, that nine persons out of every ten, when asked what book to purchase on dynamo electric machinery, will answer, "Why, Thompson's," and this, regardless of the many books and articles which have been published since the appearance of Prof. Thompson's excellent treatise.

Naturally, then, the publication of the book entitled "Practical Calculation of Dynamo Electric Machines," by Alfred E. Wiener, E. E., M. E., was looked forward to with a great deal of expectation.

No sooner had it appeared, however, than we found it attacked by men of prominence in the electrical engineering field, men whose opinions cannot pass unnoticed. The writer has read with a great deal of interest the able criticism by Mr. Thorburn Reid and the chivalric refutation of this "virulent attack" by Mr. Wellman, in the columns of The Electrical Engineer. Not being desirous of entering this controversy or prolonging a discussion which appears to become rather personal, the writer will not review any particular portion of the book, but simply make the following statement, which should be made at this time in justice to the men who give a timely warning to those intending to use the book for the "practical" calculation of dynamos or motors.

When the articles by Mr. Wiener appeared in one of your contemporaries, the writer had occasion to design a large multipolar generator. Not having had much practical experience, he freely made use of the "practical" data presented in the tables in those articles. The dynamo was designed, but had a picture of it appeared it would probably have been labeled "A Dynamo or Similar Machine Designed by One of the Inmates of ———." The professor of electrical engineering of one of the leading universities in this country testified to the correct use of the "incorrect" data and from that time on forbade the use of the data in those articles by the students in that university, and later the book, which did not have the errors corrected. Names are withheld for reasons which must seem obvious, but the force of this action based on a thorough and unbiased persual of the book, must be admitted by everyone who seeks serviceable information and will assist in purging electrical literature from unreliable and misleading statements.

ENGINEERING STUDENT.

New York, March 25, 1898.

The Telephone in Washington, D. C.

I NOTICE in the last two issues of The Electrical Engineer a statement indicating that the complaint against the Telephone Company of the District of Columbia arises from the simple fact that a party had to get a bill changed in order to pay for a message. That such is not the fact, I enclose herewith a copy of the memorial presented to Congress by those using telephones.

In the meantime, the matter is being investigated by a committee of Congress, and when their report is presented I think you will find that there is good ground for complaint.

The company controls the District of Columbia and Maryland, and it is well understood that it is practically owned and controlled by the Bell Company, to whom a large amount of stock was issued without any, or for a merely nominal, consideration. The president of the company admitted that the stock had been largely watered, and when asked what this excess of stock represented, he replied, 'The value of franchises, right of way," etc.

Inasmuch as the company has never paid one cent for its franchises, or right of way, and insists on charging rates that will enable it to pay dividends on this watered stock, it simply

amounts to making the public pay for the privileges which the public has conferred on the company.

In Baltimore, where this same company operates, the city authorities have permitted a rival company to be established, and the result is not only a much cheaper rate, but also a rental paid the city for the use of the conduits built and owned by the city, which rental already amounts to 4 per cent. on the entire cost of the conduits, and which, when the conduits are fully occupied, will amount to over 20 per cent. on their cost.

Other companies have offered to do the same here, and the citizens fail to see any good reason why it should not be done, or, in lieu of that, why the charges and rules of the present monopoly should not be regulated by law, so as to be reasonable. There is no one who is not willing that the company should charge sufficient to pay a reasonable interest on the capital invested, and beyond that no corporation enjoying free public franchises has a right to go.

As Boone, on Corporations, says, "Charters should never be granted but for the public good, in consideration of services to be rendered the public, and not to advance private gain;" and as Judge Cooley says, where competition does not exist or fails to produce reasonable service, they should be regulated by the authority which confers the franchise.

That is what the citizens here seek to have done—"only that and nothing more"—and the more corporations resist such reasonable efforts the more do they cultivate the feeling in favor of municipal ownership, or still more stringent regulations as to corporations.

Up to the present time, corporations, trusts and combines have controlled legislation, national, State and municipal; but there is an awakening of public sentiment on this subject throughout the land that will result sooner or later in a correction of the abuses, or action that will be even worse for the corporations which enjoy public franchises.

It will seem to be the part of wisdom for such corporations and their organs to meet this movement with a spirit of fairness for their own sake, as otherwise they will but "kill the goose that lays the golden eggs" for them. W. C. DODGE.

Washington, D. C., March 24, 1898.

MISCELLANEOUS

Wellman's Marine Torpedo.

IN the use of marine torpedoes, while there is no difficulty in bringing the torpedo into close proximity to the vessel to be destroyed, it is often very difficult to bring it into intimate contact therewith. Generally, it is not desired to explode the torpedo until after the diver or operator placing same has retired to a safe distance, and heretofore it has not been possible to readily secure it to the metallic armored hull of a war vessel, and, to a certainty, have it retain its original placed position, until the diver is at a sufficient distance away so as not to be injured by the final explosion.

With this in view, the torpedo invented by H. Page Wellman, of Ashland, Ky., and illustrated above, is provided with electromagnets located near its forward end, the purpose of which is to temporarily secure it to the metallic armored hull of a battleship or war vessel until such a time as the operator desires an explosion. The coils of the magnets are energized by either a primary or storage battery located within the torpedo shell. A single pole switch is included in the circuit, in series with the battery and magnet coils, which is closed by the operator before it is started on its errand of destruction. The closing of the switch terminals, permits the electrical current to circulate through the magnet coils, which create powerful magnetic fields on the ouside of the torpedo shell, the effect of which is to instantaneously secure the torpedo to the iron or steel hull of the vessel, with which it has come into contact. It will then remain securely moored in immediate contact with the hull until the battery current is interrupted either through an outside agency or through explosion.

The core ends or poles of the magnets may extend entirely through the non-magnetic shell of the torpedo or about immediately against the inside of same, also, they may be extended outside the hull of the torpedo ana to these ends may be pivotly secured magnetic metal plates which act as swivel pole pieces, and which, when the torpedo is under way, cling closely to its sides and offer but little resistance to its passage through the water. Upon coming in contact with the metallic hull of a war vessel, these swivel ends or plates open out and present a large magnetic contact area to the hull, thus more readily adopting themselves to the irregularities of the surfaces in immediate proximity. Iron linked plates or chains may also be secured to the exposed magnet core ends in place of the metal plates, care being taken that the chains are not long enough to extend between and connect the ends of the magnet cores, thus short-circuiting their magnet field and rendering their operation ineffectual.

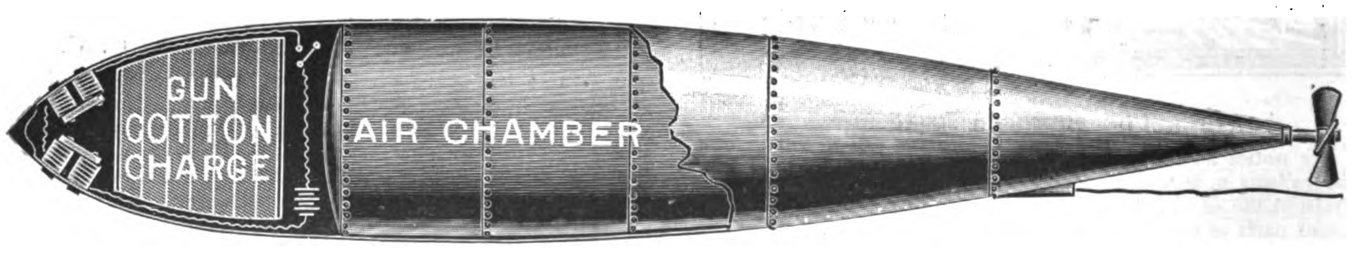
The apparatus is especially valuable with torpedoes to be used in connection with submarine boats, as upon reaching the vicinity of the vessel to be destroyed, the diver emerges from within the submarine boat with the torpedo, and, placing it in contact with the vessel's hull, he retires to a safe distance before exploding it.

Telephone In Schools.

A Chicago paper asks a question which might be put in Albany as to why the public school buildings of the city are not connected with the office of the board of education by telephones. If it is said that the expense would be too great it may be replied that there are economies that do not economize and that this is one of them.

It has happened that because of the unexpected illness of a teacher a room has had to be closed for the entire day for the reason that a substitute was not at hand, when with the use of a telephone one might have been summoned in fifteen minutes. Every principal in the city knows how he or she has been perplexed for fear that the non-arrival of coal would make compulsory the closing of the building. The way the fuel is delivered makes it possible that the building will be short of coal any day or at any time of the day. It is often the case that the attendance of a physician is immediately demanded, but there is no way of hastily summoning one. In case of fire only the ordinary appliances are at hand to call the fire department, and, while these are good, a schoolhouse with 800 children ought not to be made to depend solely on the common methods of protection in case of an emergency.

There are often times when for the public good the principal wishes for a moment's consultation with the superintendent. The truth is that one of the large school buildings has more urgent necessity for a telephone than half the business houses in the city have. These appliances are comparatively cheap



WELLMAN'S MARINE TORPEDO.

and have become private necessities, and to deprive the schools of them is virtually to cripple their efficiency and to run risks that the Board of Education ought not willingly to assume.—Albany Press.

Electrical Companies in Recent Chicago Fires.

The recent disastrous fire on Wabash avenue, Chicago, in which so many lost their lives, numbered among its victims both the personnel and property of the W. A. Olmsted Scientific Company. Mr. W. A. Olmsted, president; Mr. Arms, secretary; Mr. Wilcox, treasurer and the company bookkeeper, all lost their lives; and the stock and records were all completely destroyed. The concern seems to have been as completely wiped off the face of the earth as is possible with a corporation. The disaster is appalling. A few days later the fire which destroyed the Schoneman building on Dearborn street destroyed the property of the Atlas Electric Company, a house goods manufacturing company. The F. B. Rae Engineering Company and Sargent & Lundy also lost some goods in the latter fire.

SOCIETY & CLUB NOTES

New York Electrical Society.

The 186th meeting of the society will be held at the College of the City of New York, Lexington avenue and Twenty-third street, on Wednesday, March 30, at 8 p. m. Mr. Frank E. Knight will read a paper on "The Influence of Electric Railroads on Population and Land Values in Cities." After this paper, Mr. W. J. Clarke will give a practical demonstration of the Marconi system of wireless telegraphy by means of an improved apparatus. On behalf of Mr. John Dennis., Jr., the inventor of the Fluorometer, Mr. Clarke will also describe the operation of that instrument as a surgical adjunct of the X-ray.

American Institute of Electrical Engineers.

At the meeting of the Institute, held at 12 West Thirty-first street, New York, March 23, a paper was presented by Prof. R. A. Fessenden on "Insulation and Conduction." About 75 members and guests were present, with President Crocker in the chair. In the absence of the author, the paper was read by Mr. R. W. Ryan and discussed by Prof. Franklin and Dr. Pupin.

The secretary announced that at the meeting of the council in the afternoon the following nominees had been selected from the proposals submitted by the membership: For president, Arthur E. Kennelly; for vice-presidents, Robert B. Owens, William Stanley, Cary T. Hutchinson; for managers, Herbert Lloyd, Samuel Sheldon, George F. Sever, Charles P. Steinmetz; for treasurer, George A. Hamilton; for secretary, Ralph W. Pope.

The following officers continue their terms as provided in the constitution: Vice-presidents, A. E. Kennelly, Charles S. Bradley, D. C. Jackson; managers, J. W. Lieb, Jr., F. A. Pickernell, W. L. Puffer, L. B. Stillwell, Alexander Macfarlane, W. F. C. Hasson, Gano S. Dunn, Herbert Laws Webb.

The question of standardization of electrical machinery was referred to a special committee, composed of Elihu Thomson, Francis B. Crocker, A. E. Kennelly, C. P. Steinmetz, C. T. Hutchinson, J. W. Lieb, Jr., L. B. Stillwell.

The following associate members were elected: Albert G. Davis, acting manager, patent department, General Electric Company, Schenectady, N. Y.; Albert R. Gallatin, student at Columbia University, residence 58 West Fifty-fifth street, New York City; Herbert Gaytes, electrical engineer, Realty Syndicate Railways, Piedmont power house, Oakland, Cal.; Russell Agnew Griffin, purchasing agent, American Telephone and Telegraph Company, 15 Dey street, New York City; Francis Valentine T. Lee, engineer (Pacific coast department) Stanley Electric Manufacturing Company, 300 California street, San Francisco, Cal.; Max Loewenthal, associate editor, The Electrical Engineer, residence 831 Park avenue, New York City; Henry W. Pope, special agent, American Telephone and Telegraph Company, residence 200 West Eighty-third street, New York City; Fritz Reichmann, instructor of physics, the University of Texas, 309 East Eleventh street, Austin, Tex.; Theodore E. Theberath, Pacific coast engineer, Stanley Electric Manufacturing Company, 300 California street, San Francisco, Cal.; Robert Anton Fliess, student of electrical engineering, Columbia University, residence 201 West Fifty-fifth street, New York City.

The opening date of the general meeting at Omaha was fixed for June 27 and its continuation for either three or four days has been left with the Committee on Papers and Meetings for decision.

Large Accessions to the New York Electrical Society.

One of the most striking evidences of the general interest that the exhibition is awakening is to be found in the remarkably large accessions to its membership which the New York Electrical Society has enjoyed since the exhibition was announced under its auspices. The desire of the society to promote the welfare of electrical applications is recognized as highly laudable, and has elicited not only many words of commendation, but has brought the largest numbers of applications for membership within a given time that the society has known in its history. Last month the secretary announced a list of a round score of new members, and he now states that the applications for March will reach close upon 50. In almost every instance, the new members inquire as to the exhibition, and express the wish to aid it in any way possible.

Prize Essays.

A special committee of the Auxiliary and Educational Committee has just drawn up on behalf of the exhibition a plan whereby prizes to the value of not less than $100 are offered to the pupils in the public and private schools in New York and its vicinity for essays on the Electrical Exhibition. This committee, comprising Prof. F. B. Crocker, Mr. G. H. Guy and Mr. T. C. Martin, has realized the fact that a great many young people will visit the exhibition, not merely from idle curiosity, but from a desire to learn, and it is believed that many such visitors will be encouraged in this way in their intelligent study of electrical principles, phenomena and inventions. The essays will be limited to 1,500 words, and will be accepted up to May 18, the awards being declared and prizes presented not later than May 28. No contestant is to be over 16 years of age, and the judges will be selected chiefly from the staff of the colleges and schools of New York City. Copies of the circular will be ready this week.

Widespread Interest in the Electrical Exhibition.

The interest taken in the Electrical Exhibition is by no means limited to Greater New York, and extends in every direction. Numerous comments have been made by the foreign press, and by journals in different parts of the country, and Prof. R. B. Owens, director general of the electrical work at the Omaha exposition, beginning in June, has been specially instructed to visit this city in May, and acquaint himself with the exhibits and the work being done. Many inquiries have come from foreign managers and manufacturers, as to the time and nature of the exhibition, and it is a fact beyond question that a direct stimulus will be given to export trade. As was the case at the exhibition in 1896, many of the exhibits will go straight from the floor to foreign countries.

McCullagh Police Signalling System.

One of the universal complaints in regard to a policeman is that you can never find him when he is wanted. Many measures have been taken to remedy this state of affairs, and resort has been made to the telephone signalling systems, etc. Chief McCullagh, the head of the police force of Greater New York, who has been in the service for 30 years, has studied this

problem intimately, and has evolved a system of communication, which marks a new departure in the police supervision of any large community. He proposes to establish a certain number of policemen at stated points all over the city, connecting their booths, or sentry boxes, up by telephone with the police station of the precinct. No matter what happens, anyone who wants the help of the police can go at once to these well known points and obtain the service of the officer there, he, in turn, notifying his headquarters of the call, and securing a relay in the shape of one officer or a dozen, as the case may need. It will be obvious that such a system not only gives instantaneous police help, but by establishing a series of trochas, make it very hard for a fugitive criminal to break through, as he is liable to interception in whichever direction he goes. Chief McCullagh has kindly promised to have on exhibition at the Garden in May one of these novel and interesting booths, which, in the course of a few years, will doubtless stud the sidewalks of all our great cities.

As far as possible the method of communication will be shown in operation, and the public will be able to realize practically the manner in which a long step forward is being taken in increasing the efficiency of the police force, and in deterring crime. The city has recently made an appropriation to help carry out this McCullagh system.

The Telegraph Tournament.

Signs are already visible of the keen spirit of rivalry which has been aroused in telegraphic circles by the announcement of the coming tournament. Already the cracks in many cities, both in the States and in Canada, are getting themselves into training. Some of the Montreal operators have written to ask whether they will have the same show as their American competitors. The reply they received assured them that they would have an open field and fair play, and they are now busy getting their contingent in racing form. In other cities, such for instance as Chicago and Philadelphia, the telegraphic fraternities are uniting to raise additional prizes to be given to the successful contestant from their city at the tournament.

The complete list of judges includes the names of A. S. Brown, Western Union Telegraph Co.; Francis W. Jones, Postal Telegraph Co.; A. E. Sink, manager Western Union Telegraph Co.; Chas. Shirley, manager Postal Telegraph Co.; Geo. H. Usher, superintendent Postal Telegraph Co.; D. B. Mitchell, manager Race Bureau, Western Union Telegraph Co.; Minor M. Davis, traffic manager, Postal Telegraph Co.; Gardner Irving, manager Commercial News Dept., W. U. T. Co.; S. F. Austin, Commercial Cable Co.; P. J. Tierney, manager Central Cable Office; F. F. Norton, and S. A. Coleman, chief operators Postal Tel. Co.; E. F. Cummings, night manager Western Union Tel. Co.; Edwin F. Howell, secretary Serial Loan Ass'n; E. T. Barberie, Postal Telegraph Co.; Chas. Thom, chief of Quadruplex Dept. Western Union; E. H. Cox, manager, and E. W. H. Cogley, assistant superintendent Associated Press; Thos. R. Taltavall, editor Electrical World; E. A. Leslie, Manhattan Electric Light Co.; J. H. Bunnell, Electrical Manufacturer; H. W. Pope, Telephone Supt.; Wm. Maver, Jr., Electrical Expert; Robt. W. Martin, cable editor N. Y. Sun; P. B. Delany, Telegraph Expert; Edward H. Johnson and Thos. J. Smith, Electrical Manufacturer; Judge of Press Code, Ed. H. Curlette and P. T. Brady. All the judges are expert telegraphers. The selection has been so carefully made and the list includes so many men in the front of the electrical as well as the telegraphic industry, that every contestant may be assured that his individual interests will be protected. Phonographic and other records of each transmission will be made, so that in the event of any dispute the work may be reproduced. The judges of the typewriting contest are Chas. W. Price, editor Electrical Review, T. C. Martin, editor Electrical Engineer, W. D. Weaver, editor American Electrician, J. B. Taltavall, editor Telegraph Age and G. H. Guy, secretary New York Electrical Society.

MR. SOL. BERLINER, who has been confirmed as U. S. Consul to the Canary Islands, will be glad to come into touch with electrical concerns that desire to introduce their goods in the Islands or be represented there. He leaves on April 7 and can be addressed at 271 Broadway.

MR. JAMES BURKE, the well known designer of dynamo electric machinery, has sailed for Europe. He has accepted the position of consulting engineer for the Bergmann Electromotoren & Dynamo Werke of Berlin, in which Mr. S. Bergmann, of this city, is so prominently interested. He carries with him the good wishes of a host of friends and admirers.

MR. ERNST THURNAUER, director of the French Thomson-Houston Company, has been here on a short trip and has just returned home to Paris. He is much gratified at the progress here and with prospects in France.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued March 22, 1898.

Alarms and Signals:—

BURGLAR AND FIRE ALARM. D. H. Talbert, Knightstown, Ind., 601,181. Filed Oct. 29, 1897. The opening of a door or window releases a normally closed push button held out of contact by a weight.

ELECTRICAL ALARM-GAUGE. J. Hackney, Norfolk, Va., 600,866. Filed June 24, 1897. The indicating needle makes contact with contact points imposed in its path at predetermined points.

Batteries, Primary:—

BATTERY. W. Morrison, Montclair, N. J., 601,042. Filed Jan. 20, 1896. A battery case consisting of non-conducting material and having an independent cap molded in it insulated from the top and opening into the interior of the case, and a carbon provided with a shoulder driven in the cap.

Conductors, Conduits and Insulators:—

CONDUIT. L. Skaife, Montreal, Canada, 600,935. Filed June 5, 1897. Comprises a conduit length of oblong form having parallel flat top and bottom, inclined sides, and a centrally located longitudinal circular passage, the sides being at such angles as to make them radial from a given center.

HIGH POTENTIAL INSULATOR. J. W. Boch, East Liverpool, Ohio, 601,195. Filed Feb. 1, 1898. A high potential porcelain insulator having a supporting post made of two tubes, one fitted within the other with an intermediate tubular layer of glaze.

Dynamos and Motors:

ALTERNATING CURRENT MOTOR. W. Langdon-Davies, London, England, 601,023. Filed Nov. 15, 1897. An alternating current motor in which the starting coils are of numerous turns and relatively high self-induction as compared with the running coils in which a resistance is added starting to the circuit through the running coils.

Electro-Metallurgy:—

METHOD OF AND APPARATUS FOR EXTRACTING GOLD FROM ITS ORES. E. W. Von Siemens, deceased, F. W. Whitridge, administrator, New York, 601,068. Filed May 28, 1890. An apparatus for obtaining gold from a weak cyanid solution by electrolysis, combining a cell provided with anodes of iron and cathodes of lead formed of thin plates, the cathode plates having from nine to ten square meters of surface to each ton of solution in the cell, and subjecting it to a weak current of electricity.

Lamps and Appurtenances:—

ELECTRIC CIRCUIT CLOSING DEVICE. G. Newman, El Paso, Tex., 600,969. Filed Sept. 27, 1897. A key for lamp sockets in the face of which is imposed a recess, the inner part of which is covered with phosphorescent paint.

CLUSTER FIXTURE FOR ELECTRIC INCANDESCENT LAMPS. N. Weeks, New York, 601,108. Filed Oct. 1, 1897. A fixture that may be applied directly to a ceiling and in which the usual short extended end of the house-wiring may be attached directly to the lamp contacts.

Measurement:

ELECTRICAL MEASURING INSTRUMENT. E. Weston, Newark, N. J., 600,981. Filed Dec. 7, 1897. Comprises two current measuring instruments attached to a common base and having their indicating needles so located with relation to a common scale that independent readings may be taken at the same instant.

ELECTRICAL MEASURING INSTRUMENT. E. Weston, Newark, N. J., 600,982. Filed Dec. 7, 1897. The removable coil is either partially or wholly immersed in a dampening liquid.

ELECTRICAL MEASURING INSTRUMENT. E. Weston, Newark, N. J., 600,983. Filed Dec. 7, 1897. Designed for alternating currents and provided with two indicating needles and a scale wholly inclosed within the casing of the instrument, one of the needles being operatively connected with the movable part of the instrument and the other with extraneous means for mechanically moving it to various positions.

Miscellaneous:—

ELECTRICAL DEVICE FOR PROPELLING BOATS. L. R. Jones, Boston, Mass., 600,874. Filed July 2, 1895. Employs a motor mounted on the rudder shaft and adapted to turn a propeller by means of its shaft connected to the screw by bevel gear.

DAMPER GOVERNOR. C. Kummer and T. Bertrand, Easton, Pa., 600,966. Filed May 9, 1896. Controlled by a thermostat in conjunction with electrical apparatus connected to a battery.

IGNITING DEVICE. J. T. Armstrong and A. Orling, London, Eng., 601,069. Filed Dec. 21, 1896. Designed for gas lamps. Details of construction.

MAGNETIC CLUTCH AND POWER STATION SYSTEM. B. J. Arnold, Chicago, Ill., 600,941. Filed June 20, 1896. Combines with a driving shaft, two power transmitting shafts, one hollow and encircling the other, a power transmitter normally operatively connected with the hollow shaft, and a driving connection device adapted

to operatively connect the hollow shaft with either of the other two shafts.

Railways and Appliances:—

BRAKE FOR ELECTRIC MOTOR CARS. P. B. Hayes and H. M. Carbine, Chicago, Ill., 601,206. Filed Dec. 23, 1896. Comprises a wheel brake mechanism, an auxiliary brake mechanism for the armature shaft of the motor and an equalizing lever operated from the car platform and having operative connection with the wheel brake mechanism and the armature shaft brake mechanism.

TROLLEY WHEEL. A. B. Collett, Lynn, Mass., 600,857. Filed May 28, 1896. Means whereby the material worn from the wheels by contact against the trolley wire may be supplied without the necessity of a new wheel body.

TROLLEY WHEEL. E. R. Robinson, Chicago, Ill., 600,890. Filed Nov. 28, 1896. Combines with the fillings of the wheel, of shots of the filling material, which extend through openings in the wheel to electrically connect the lining with the trolley arm independently of the main body of the wheel.

PNEUMATIC CONTROLLING SYSTEM FOR ELECTRIC CARS S. H. Short, Cleveland, Ohio, 600,896. Filed Sept. 20, 1897. Comprises pneumatic means for controlling all the motor controllers in a train of cars from any car in the train.

ELECTRIC CONTACT BOX. J. N. Thomas, Johnstown, Pa., 600,937. Filed Sept. 18, 1897. Combines with the terminals of a switch, means for opening the circuit thereto when the separation of the terminals draws an arc between them, the means being actuated by the heat developed by the arc.

Roentgen Rays:—

PORTABLE CAMERA FOR ROENTGEN RAY PHOTOGRAPHY. G. Seguy, Paris, France, 601,172. Filed March 23, 1897. Comprises a complete installation, consisting of a battery, and induction coil, a Crookes tube, and the parts required for a complete operation encased in a portable box of relatively small size.

Telephones:—

TELEPHONE. G. F. Payne, Philadelphia, Pa., 600,990. Filed Aug. 21, 1897. Employs a perforated electrode adjacent to the diaphragm, a rod extending from the diaphragm through and movable in the perforated electrode, an electrode secured to the rod and granular conducting material situated between the electrodes.

TELEPHONE TRANSMITTER. G. F. Payne and W. D. Gharky, Philadelphia, Pa., 600,991. Filed Sept. 11, 1897. Provides a transmitter in which the form and amplitude of the vibrations of the diaphragm will be converted into alternating electrical impulses.

DROP SIGNAL APPARATUS. O. A. Danielson, Owatonna, Minn., 601,222. Filed May 13, 1897. A series of sets of magnets, a set for each drop, comprising a multiplicity of magnets, adjacent sets being so arranged that magnets of one set will oppose magnets of the adjacent set.

LEGAL NOTES

The Stieringer Fixture Patent Sustained.—George Maitland vs. B. Goetz Mfg. Co.

On March 2 the United States Circuit Court of Appeals for the Second district handed down a decision upholding the validity of claim No. 1 of the reissued Stieringer fixture patent, reissue No. 11,478, March 11, 1895. In an extended opinion the Court reviews the testimony and holds that both on the ground of novelty, as well as of patent ability, the Stieringer reissue is valid.

THE STOCK MARKET

Fears of War and Lower Prices.

The general state of trade continues excellent, and some branches are extremely busy. In iron and steel the demand is enormous, not for warlike purposes merely, but in the beneficent arts of peace. A pig iron famine even is predicted. The reports of the activity of interior trade are very encouraging, and it is evident that the conditions everywhere would have approached a "boom," but for the nervousness induced by the prospect of war.

On the Stock Exchange last week, 14,618 shares of Western Union exchanged hands at prices between 86 and 82¼, closing at 84½. General Electric, after sales of 8,930 shares, closed at 31¾. New York Edison sold at 125¼. In Boston, American Bell telephone on sales of 982 shares fell to 240 from 244½, the dividend "coming off." Calumet and Hecla, copper stock, went to 515, on sales of 11 shares.

Prices in the metal trades are strong. Copper is 12 cents, heavy steel rail is $17.50. The Western Wire Consolidation is practically an accomplished fact, but the smaller consolidation of electrical insulated wire interests is said to be hanging fire.

TRADE NOTES & NOVELTIES

Large Sales of The Triumph Electric Co.

WE publish below the large and interesting list of sales made by the Triumph Electric Company, of Cincinnati, O., between March 1 and 15. Their business has been very satisfactory for many months, and since the beginning of the year they have received orders for 95 machines: J. H. Curran, Cincinnati, O., one 5 h. p. elevator motor and controller; County Jail, Louisville, Ky., one 4 k. w. 110-500-volt motor generator; Electrical Supply Co., Madison, Wis., one 5 h. p. 500-volt m. s. motor; Banner Laundry, Cincinnati, O., one 15 k. w. slow speed generator; R. N. Parshall & Co., Owosso, Mich., one 67 h. p. 500-volt moderate speed motor; Langstadt & Crosswell, Neevah, Wis., one 3 k. w. 120-volt slow speed generator; Chicago Heat, Light and Power Co., Chicago, Ill., two 100 k. w. 125-volt moderate speed generators; J. W. Chester, Nashville, Tenn., one 3 k. w. 110-volt slow speed generator; J. E. Caudle, Richmond, Va., one 2 h. p. 220-volt motor; J. I. Hathaway, Los Angeles, Cal., one 5 h. p. 500-volt moderate speed motor and one 7½ h. p. 500-volt moderate speed motor; J. E. Caudle, Richmond, Va., one 5 h. p. 220-volt moderate speed motor; J. H. Curran, Cincinnati, O., three 10 h. p. 500-volt slow speed elevator motors and controllers; Rogers Iron Co., Springfield, O., one ¾ k. w. 110-volt slow speed generator; Cascade Milling Co., Sioux Falls, South Dak., one 5 h. p. bipolar motor; J. E. Caudle, Richmond, Va., one 2 h. p. 220-volt slow speed motor; Krippendorf & Dittman Co., Cincinnati, O., one 1 h. p. 110-volt slow speed motor; J. A. Britenstool, Rochester, N. Y., one cloth cutter; Geo. B. Sickles & Co., Tate, Ga., one 5 h. p. 120-volt moderate speed motor; Peninsular Light and Power Co., Orlando, Fla., one 30 k. w. 250-volt moderate speed generator and one marble switchboard; Hughes Mfg. Co., Hamilton, O., one 30 h. p. 300-volt moderate speed motor.

Large Amount of Railway Material Needed.

Below is given a list of overhead material required for the construction of the Springfield and Southwestern Street Railway Company: 920 wood adjustable brackets, style B, 7½-ft. arm; 1,010 type D malleable iron straight line hangers, 150 type D malleable iron single curve, 90 type D malleable iron double curve, 40 type D malleable iron barn hangers, type D hanger wrenches, 900 type K straight line ears 15" soldered, 20 type K double strain ears 15" soldered, 150 type K feeder ears 15" soldered, 240 type K straight line ears, deep groove; 50 splicing sleeves, 2-0 trolley wire; 180 globe strain insulators, 30 globe strain insulators with clevis, 10 Detroit section insulators, 1,760 feeder wire insulators, 20 Brooklyn strain insulators, 1,760 cross arm braces, 20"; 1,760 cross arm pins, iron; 330 eye bolts, 1½" x 12". Mr. Jesse W. Starr, Hartford, Conn., can be addressed on the subject. While he specifies certain makes of material, he does not limit himself necessarily to that make. He will also require spikes, rail bonds, etc.

The Cross Electrical Company, Buffalo, N. Y.

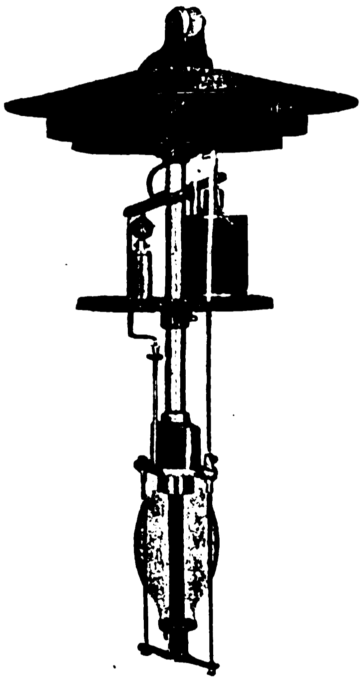
Fred J. Cross, L. Riegel and John Atkins have formed a partnership that will be known as the Cross Electrical Company and have opened a suite of rooms in the Mooney-Brisbane building, where they will carry in stock and handle dynamos, motors, transformers, telephones and a general line of electrical supplies. Mr. Cross, who will act as manager for the company, has had a wide experience in the electrical field and will no doubt with the aid of his able partners, make a success of their new venture. The company also have a department for the refilling of incandescent lamps.

UNIVERSAL FIRE ALARM COMPANY are equipping the buildings and manufacturing establishments of Camden, N. J., with their automatic fire alarm system.

Upton "Midget" Enclosed Arc Lamps to Operate Singly on Constant Potential Circuits.

THE construction and appearance of the Upton Midget lamp to operate singly on constant potential circuits of 220 volts, is identical with the 110-volt constant potential lamp manufactured by the Standard Thermometer and Electric Company, of Peabody, Mass. There is a slight change in the magnet and construction of the clutch rod necessitated by the difference in the current; this is clearly shown in the figure.

The lamp is designed to take from 2 to 3½ amperes, the standard being 2½ amperes, with approximately 150 volts across the arc. The high voltage of the arc makes it very flexible and capable of standing a fluctuation of 50 volts without affecting the light. This makes the lamp especially desirable on 220-volt power circuits of varying loads. It also enables single lamps to be furnished storekeepers for operation independently. The lamp has the same wattage consumption at 2½ amperes as the 110-volt lamp at 5 amperes. It has a very handsome exterior appearance, as have all the lamps manufactured by the above named company.



MECHANISM OF THE UPTON "MIDGET" ENCLOSED ARC LAMP TO OPERATE SINGLY ON CONSTANT POTENTIAL CIRCUITS.

Sprague Electric Co.

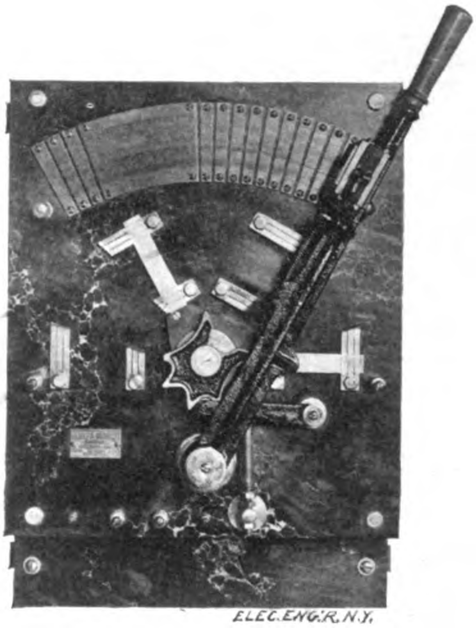
The organization of the Sprague Electric Company, which our readers well know, was formed by the consolidation of the Interior Conduit and Insulation Company and the Sprague Electric Elevator Company, is being rapidly perfected. The offices of the company now occupy practically the whole of three floors in the Commercial Cable building. The company recently secured a suite of rooms in the Marquette building, Chicago, which will be in charge of Mr. Millard B. Kitt and Mr. E. B. Kittle, long identified with the company. Well-known electrical men and houses are being rapidly secured to represent the Sprague Company in various sections of the country, and the organization bids fair to be a remarkably strong one in every way.

An advertising and press bureau is one of the new departments of the Sprague Company, and it has been installed in a suite of rooms on the nineteenth floor of the Commercial Cable building.

EASTERN ELECTRICAL CONSTRUCTION COMPANY, of Philadelphia, has been formed by W. D. Barnard, W. Hoopes, E. M. Jarnall, J. Mustard and G. E. Johnson, with a capital stock of $50,000.

American Rheostat Co.'s Reversible Printing Press Controller.

THE reversible printing press controller, illustrated below, has recently been introduced by the American Rheostat Company, Milwaukee, Wis., and is claimed to possess decided advantages over any similar device now on the market. This controller has a double pole, reversing snap switch, which is operated automatically by the throw of the lever, opening the circuit when the lever is brought to the central position, and closing the circuit when it is moved backward or forward. With this controller, sparking on the contacts is done away with, the parts are easily accessible and renewable, and of first-class material and workmanship. The instrument gives a variation of twelve different speeds on the forward motion and three on the backward motion, allowing the motor to reverse slowly. A large number of these controllers have recently been installed and they are giving the best of satisfaction, as they prevent any possibility of damage to the motor through the carelessness of the operator.



AMERICAN RHEOSTAT CO.'S REVERSIBLE PRINTING PRESS CONTROLLER.

Simplex Friction Tape.

In presenting a tape to the public an advertiser can make no fairer proposition than that of offering to send to any person interested a sample free of expense. This is the offer made by the Western Electric Company in regard to the Simplex friction tape, and upon receipt of an inquiry they will mail a small sample roll of this tape to the address of the person requesting it. The Western Electric Company knows the merit of the tape offered for sale and feels sure from their past experience that when a customer has once tried a sample that he will send in his order for this tape when he is in the market.

Micanite Abroad.

The Mica Insulator Company, whose offices are at New York and Chicago, with a branch at London, Eng., recently received from one of the large builders of electrical machinery abroad orders for over 5,000 "Micanite" segments of a large pattern (many of which were more than 17 inches in length), and from another leading manufacturer of electrical apparatus an order for 2,000 segments, also from one of the leading motor builders an order for 26,000 segments. This volume of business would indicate that the company's "Micanite" segments are meeting with favor among machinery builders. The company claim that their segments are softer and wear down more evenly than mica segments. Therefore, they give better satisfaction.

A sample set of segments for any one of the smaller machines will be furnished free of expense to electrical manufacturers or repair concerns who are desirous of demonstrating the value of the segments.

Sales of Ball Engines.

The new Bellefield Hotel, Pittsburg, Pa., will have its own electric light plant, consisting of three Ball engines, built by the Ball Engine Company, Erie, Pa., direct connected to Westinghouse dynamos. McNeil Bros. of Chicago have recently placed in their building a Ball engine, built by the Ball Engine Company. The engine is direct connected to a Western Electric Company dynamo. The American Bank building, Kansas City, Mo., recently installed an electric plant. Two Ball engines direct connected to Western Electric Company dynamos furnish the power.

Erickson Outlet Insulators.

THE Erickson outlet insulators are now manufactured for use in conjunction with all styles and sizes of conduits for interior wiring installations. Since their introduction two years ago they have steadily gained favor among engineers and enter-

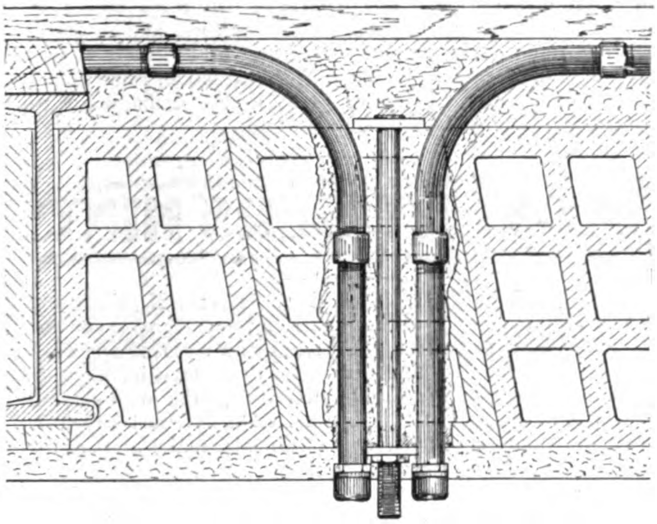


FIG. 1.—METHOD OF INSTALLING ERICKSON'S CEILING OUTLET.

prising contractors, as a device that adds to the safety and completeness of the work in their charge. The insulators are made in substantial form, having a threaded metal member to receive

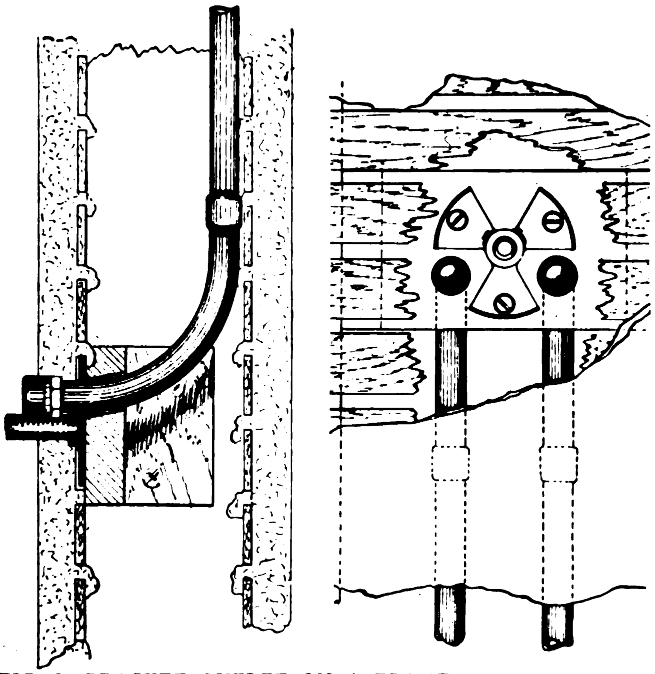

FIG. 2.—BRACKET OUTLET ON A FRAME PARTITION.

the conduit pipe, the outer end being enveloped by an insulation of the highest grade obtainable.

The design of the insulator is such as to admit of its easy installation; standard tools used in connection with conduit work are all that are required to set the insulators securely in place.

The old method of projecting the ends of the conduits at the outlets has been a source of considerable danger, to say nothing of the expense necessary to keep the canopies of fixtures from grounding. The outlet insulators not only prevent the above difficulty, but also provide a smooth insulating finish that enables the wires to be drawn in or out of the conduits with immunity from chafing or cutting of the insulation.

Fig. 1 illustrates the method of installing ceiling outlets in a building constructed with fireproof arches. Fig. 2 shows a

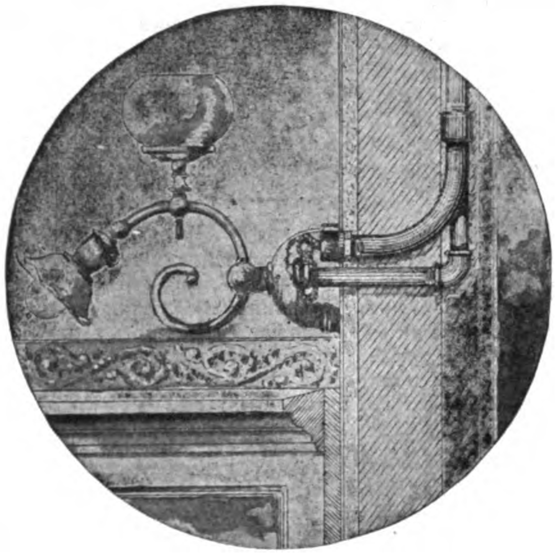

FIG. 3.—EXTERIOR VIEW OF ERICKSON'S INSULATOR.

bracket outlet on a frame partition. Many important buildings have of late been equipped with these outlet insulators, the general verdict being that they made an ideal outlet finish at a minimum cost. The Erickson outlet insulators are handled exclusively by C. S. Knowles, the well-known supply house, No. 7 Arch street, Boston, Mass.

Plant for Chili.

The Westinghouse Electric and Manufacturing Company and Westinghouse, Church, Kerr & Company have just received the contract for the entire equipment of machinery and electrical apparatus for a large electric lighting plant in Chili, being erected at Punta Arenas, the extreme southern end of that country. The buildings for the new station have been completed, and the machinery will be installed at once by Pittsburg machanics.

American Range Finder Co.

The American Range Finder Company has made an assignment to Charles B. Van Nostrand. The company was incorporated in 1888, with a capital stock of $500,000, to manufacture the ingenious range finder, invented by Lieutenant B. A. Fiske, to determine the distance and location of ships at sea. Soon after the company was started the government placed the finder in use on the cruisers Chicago and Baltimore.

Metropolitan Electric Construction.

The Metropolitan Electric Construction Company is now doing all of the installation work of the Sprague Electric Company, an arrangement to that effect having been recently closed. The announcement was made in a striking two-color circular by the Sprague Company, in which circular it was pointed out that the Construction Company would not only contract for installation and maintenance of Sprague machinery, but of any other machinery as well. The offices of the Construction Company, as well as those of the Sprague Company, are in the Commercial Cable building. The officers are W. D. MacQuesten, president and general manager, and Mr. Wallace E. Carver, treasurer.

OWOSSO, MICH., is receiving a new telephone switchboard built by the Detroit Switchboard and Telephone Construction Company, for 300 numbers.

CATALOGUES.

A Modern Gear Plant.

Steel gears and pinions form the subject of a small pamphlet, well illustrated and printed, issued from the press of the General Electric Company, under the title "A Modern Gear Plant." It contains a description of the extensive plant which that company has established at the River Works at Lynn, for the exclusive manufacture of steel gears and pinions, equipping it throughout with the most modern machinery. This pamphlet will be sent on application to any of the company's sales offices, one of which is found in every large city in the United States.

Western Electric 1898 Fan Motor Catalogue.

A very handsome and elaborately illustrated catalogue and price list has just been issued by the Western Electric Company, New York and Chicago, illustrating and giving the prices of their 1898 fan specialties. Fans for direct and alternating current circuits, with variable speeds, for desk and ceiling use, are shown in perspective and section, and show the great variety of these goods manufactured by this company.

H.-C. Direct Current Fans.

The Holtzer-Cabot Electric Company, Brookline, Mass., have issued a very neat catalogue for their fans for the season of 1898. These motors are of the direct current type, spherical in form, all laminated, no outside wires, carbon brushes self-feeding, four-speed switches, grease cups for lubrication, bearings of phosphor bronze. The 12-inch and 16-inch fans are alike in style this year, and are both very handsome. The catalogue gives full details, and copies should be secured at once.

Catalogue of the Joseph Dixon Crucible Co.

The superiority of Dixon's pure flake graphite over oil as a lubricant is set forth in a neat little pamphlet issued by the Joseph Dixon Crucible Company of Jersey City, N. J. Comparative tests of oil and graphite made by Prof. Thurston are presented and show a decided advantage of graphite over oil. The pamphlet contains much valuable information on the subject of lubrication and would prove of interest and value to every central station man and user of machinery.

Catalogue of the National Pipe Bending Co.

The National Pipe Bending Company of New Haven, Conn., set forth in an admirable pamphlet the many advantages possessed by the National feed water heater manufactured by them. This heater has now been sold for over fifteen years, during which time it has come into very general use in all parts of the country and its great efficiency and reliability are to-day as well attested as any other facts in the whole science of engineering. This is due to the simple common-sense theory upon which the heater is planned and the thorough and workmanlike manner in which it is constructed. The record of the company is 800,000 horse power in daily use. The advantage of the heater may be summed up as follows: No inside joints to leak, no straight tubes to leak, no back pressure is possible, no contact of the water with the shell or iron, no chance of grease in the boiler; and economy of coal, space and price. The catalogue is profusely illustrated, showing the various types of heaters and their uses and numerous shapes and styles of coils.

Catalogue of the Ball Engine Company.

A very handsome and unique catalogue has just been issued by the Ball Engine Company, of Erie, Pa. It consists of a folder, on which are printed in crimson and pale green type the many advantages possessed by the Ball engine. A beautiful half-tone cut of the engine printed on white paper is pasted on the middle page of the folder and makes the production both novel and artistic. The folder is enclosed in a greyish cover, on which are embossed the significant words "A Modern Engine." The main advantages of the engine here brought out are the gravity system of oiling, the automatically adjusting valve and the closely regulating, automatic governor.

The Electric Gas Lighting Co.'s Catalogue.

One of the most useful and complete catalogues and price lists of electrical house goods is that of the Electric Gas Lighting Company, of 195 Devonshire street, Boston, Mass. The catalogue contains cuts and prices of every conceivable electrical apparatus for house, line and office use. The typographical work of the catalogue is excellent and the very complete index renders it of great value to every one selling or installing goods manufactured by this company.

An Important New Fan Motor Catalogue.

The Sprague Electric Company, Broad street, New York City, have just published what they claim to be the handsomest catalogue of fan motors ever printed, and they have it now ready for distribution. The catalogue embraces all of their new types of ordinary and ceiling fan motors, and is enclosed in a rich green cover, printed in red and gold, giving it an unusually beautiful effect. We strongly recommend our readers to secure one of these catalogues early, as the demand for them is great, and they will soon be exhausted.

ADVERTISERS' HINTS

McINTOSH, SEYMOUR & CO., Auburn, N. Y., illustrate a horizontal tandem gridiron valve engine arranged for direct connection to a generator. All types and sizes of engines are designed and built by this firm, and they have installed their machines in some of the largest electrical plants in this country.

THE MERRIMAC CHEMICAL CO., 13 Pearl street, Boston, manufacturers of acids and chemicals, make a specialty of battery acids. A card will elicit prices.

WM. J. MURDOCK & CO., 160 Congress street, Boston, build switchboards of all styles. A description of those they furnished the Boston Hospital may be found in another article in this issue.

MONTGOMERY & CO., 105 Fulton street, New York, supply tools for rough and fine work for every trade and at various prices.

THE STANDARD THERMOMETER AND ELECTRIC CO., Peabody, Mass., have introduced an enclosed arc lamp, to burn on 220-volt circuits consuming 2½ amperes at 150 to 160 volts at arc.

JNO. A. ROEBLING'S SONS CO., Trenton, N. J., advertise their bi-metallic wire. As it is claimed, this wire has 35 per cent. more resistance than pure copper wire of the same diameter, and is much cheaper to install.

THE READING ELECTRICAL MFG. CO., 739 Penn street, Reading, Pa., say they can save their customers money on supplies, ammeters and voltmeters and bicycle lamps.

THE WESTINGHOUSE ELECTRIC AND MFG. CO., Pittsburg, Pa., mention a list of apparatus brought out by them as a contribution to science.

THE RIDGWAY DYNAMO AND ENGINE CO., Ridgway, Pa., call attention to the special coils provided in their generators for balancing armature reaction and securing perfect commutation with absolutely fixed brushes.

THE NATIONAL CARBON CO., Cleveland, O., advertise a carbon process cup cell with the carbon element all in one piece.

G. M. ANGIER & CO., 64 Federal street, Boston, Mass., advertise Paragon arc lamps for 110, 220 and 500-volt currents.

C & C ELECTRIC CO., 143 Liberty street, New York, recommend those who are looking for the most modern and most efficient lighting and power apparatus to correspond with them.

THE LYNN INCANDESCENT LAMP CO., Lynn, Mass., offer new "Lynn" incandescent lamps at twenty cents, renewed lamps at fifteen cents, or to renew lamps at twelve cents.

THE SCHNEIDER MFG. CO., Cleveland, O., are ready with their water-motor fans for the '98 season.

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, Ill., recommend the "Newgard" combined waterproof socket and globe as a protection for lamps exposed to moisture

in breweries, paper mills, packing houses, etc. A sample may be obtained for 60 cents.

K. & W. CO., Pittsfield, Mass., report excellent business in both the "Hardy" incandescent lamp and electrical supplies. Their works are running to their full capacity and the company has a large number of orders on hand.

THE HUNTER FAN AND MOTOR CO., Fulton, N. Y., illustrate their 1898 models of ceiling fans for direct and alternating currents.

THE BEATTIE ZINC WORKS CO., Reading, Mass., are making a special shaped zinc which permits of its complete utilization.

THE SPRAGUE ELECTRIC CO.'S fan motor catalogue is, as they claim, a work of art. It describes all their latest types and models and may be obtained by addressing their press department at 20 Broad street, New York.

THE HOLTZER-CABOT ELECTRIC CO., Brookline, Mass., advertise noiseless, artistic fan motors having four speeds and many other pleasing and economical features.

THE WESTERN ELECTRIC CO., Chicago and New York, advertise a large variety of fan motors to suit all conditions.

A. T. THOMPSON, 26 Bromfield street, Boston, Mass., carries a large stock of optical projection apparatus for photo-engraving, stage lighting, etc., as well as stereopticans, magic lanterns and accessories.

UEHLING, STEINBART & CO., 63 Mulberry street, Newark, N. J., call attention to the saving in fuel that may be effected by the use of the gas composimeter. This instrument was fully described in our last issue.

NEW YORK NOTES.

SPENCER, TRASK & CO., 27 and 29 Pine street, New York, City, have just issued an admirable little pamphlet, illustrated, reviewing the Edison Companies of New York and Brooklyn, from the investor's standpoint. It goes into exhaustive review of the statistics relative to these stable properties and their splendid growth. Copies will be sent to those who may desire.

WESTINGHOUSE ELECTRIC & MFG. CO. have declared a regular quarterly dividend of 1¾ per cent. on the preferred stock, payable April 1.

REGER & ATWATER CO. have been incorporated to deal in mechanical and electrical supplies by A. P. Reger, W. M. Reger, P. A. Reger, M. E. Reger and R. D. Duke.

THE CHERRY ELECTRIC WORKS, of New York, are meeting with well deserved success in the manufacture of their low-priced direct reading ammeters and voltmeters. They have now well introduced these instruments, which are becoming popular on account of their accuracy, combined with extremely moderate cost.

E. G. BERNARD COMPANY, Troy, N. Y., have contract to furnish the Dobler Brewing Company, of Albany, N. Y., with two 60 h. p. direct connected generators, one electric elevator, seven motors and all the outfit necessary for a lighting plant.

ROCHESTER ELECTRIC MOTOR COMPANY, of Rochester, N. Y., has undergone recently some changes in its management. The present officers are: F. C. Kinmel, president; Edw. F. Davison, secretary and treasurer; P. J. McDonald, superintendent. The company have moved from 20 Spring street, to the corner of Mill and Platt, where with increased floor space and new machinery they are in a position to turn out a large quantity of product, and, if possible, better goods.

NIAGARA FALLS, N. Y. The Cataract General Electric Company of New York City, which holds the right to equip the canals of the State with appliances to propel boats by means of electricity, has filed in the office of the Secretary of State a certificate of continuation of its corporate existence for five years, from November 3, 1898. The company was orginally incorporated in 1893, for a period of five years. The certificate is attested by Frank W. Hawley, Charlton T. Lewis, William Mertens, C. P. Vedder, J. S. Bache, Charles Ambrecht and Peter F. Meyer.

BROOKLYN, N. Y. The Queens Borough Electric Light and Power Company has been formed to supply gas and electricity for lighting the streets and houses of New York City and of the Counties of Kings, Queens and Suffolk; capital stock, $250,000. Directors: Van Wyck Rossiter, David H. Valentine, Royal C. Peabody, C. L. Rossiter, and T. S. Williams, Brooklyn; Frank Macgovern, Manhattan; Joseph C. Biglin, Far Rockaway; Isaac M. Sutton, Flushing, and J. Hobart Potter, Jr., Lawrence.

STANDARD ELECTRIC COMPANY has been formed at Binghamton, N. Y., with a capital stock of $5,000, to make and sell electrical and mechanical devices, etc. The directors are C. F. Terhune, Lavelle M. Blanding and Robert E. Prince. The firm is a consolidation of the firms of Lavelle M. Blanding and Roloson & Tileston.

WAPPLER ELECTRIC CONTROLLER COMPANY, of New York City, has been formed with a capital stock of $5,000 by R. H. Wappler, J. C. F. Jacoby and Chas. Fayer.

HUDSON, N. Y.—A bill is before the State Legislature to incorporate the Jansens Kil Electric Power Company, of Hudson, with W. A. Harder, Jr., of Hudson, and P. M. Harder and C. N. Harder, of Philmont, interested. The capital is $100,000. The plan is to utilize electrically the power on the Roeliff-Jansens-Kil in the counties of Columbia and Dutchess.

THE DIESEL MOTOR, which has attracted such universal attention as a new type of engine is to be shown in operation at the Electrical Exhibition, Madison Square Garden, in May. It is to be shown in October at the exhibition of the Massachusetts Charitable Mechanics' Association in Boston.

PAN-AMERICAN EXPOSITION.—Owing to the troubled condition of our international affairs, and the unwillingness of Congress to lessen the amount available for defense appropriations by a grant for the Exposition at Niagara just now, the management has postponed the affair until 1900 or even a year later. Electrical exhibitors who proposed to show there next year are now concentrating their effort on the big show to be held at Madison Square Garden this May.

WESTERN NOTES

WESTERN ELECTRIC CO. is sending out a circular of the Star Soldering Stick. This soldering stick is a complete substitute for acids, resin and soldering salts and will not corrode metals.

MISSOURI VALLEY ELECTRIC LIGHT COMPANY, in writing of the Lakon transformer, states that they have had a number of them in circuit for two years, which have given excellent service. Wherever these transformers are used, the purchasers are well satisfied. The manufacturers of the Lakon transformer have recently completed a large three-story brick factory, which is equipped with the very best facilities, to enable them to manufacture transformers to the best possible advantage. Their laboratory is most complete, being fitted up with a full complement of instruments with which to make exhaustive transformer tests, and thus they are assured of the quality of the transformers before they are shipped to purchasers. These transformers are handled by the Western Electric Company, of Chicago and New York.

IOWA.—The State Senate has passed a bill authorizing cities to purchase, construct and operate telephone exchanges. Its chief object is said to be to permit Des Moines to acquire the Mutual Telephone Company, of that city, an independent "unremunerative property."

THE ARMOUR ELEVATOR, Chicago, has recently started up a Ball engine, built by the Ball Engine Company, Erie, Pa., for electric purposes. The Eden Musee, of Chicago, has also recently installed for lighting an Erie Ball engine.

BAY CITY, MICH.—The Valley Telephone Company has ordered 1,500 telephones, etc., from the American Electric Telephone Company, of Chicago, and the first of these will be placed in West Bay City.

EAU CLAIRE, WIS.—R. E. Rast, receiver of the National Electric Manufacturing Company, has been ordered by the Court to turn over all books and vouchers to the Court, as the result of a petition for a general overhauling of the receivership. There is about $100,000 involved.

THE WESTERN ELECTRIC COMPANY in advertising the Simplex tape offers to send samples free to those who desire to use it, stating that they need not purchase until they are convinced of its superior merits.

THE W. E. NON-SPARKING BRUSHES have proven, it

is said, one of the best preventives of the disastrous sparking which so frequently interferes in the successful operation of a dynamo. They are now being used in almost every city in the United States. A circular giving regular stock sizes and price lists of these brushes will be mailed by the Western Electric Company to any one desiring information in regard to them.

MR. W. R. GARTON, 414 Ashland Block, Chicago, will act as the Western representative for W. E. Kline & Company, 123 Liberty street, New York, for the sale of their miniature and decorative incandescent lamps.

SAULT STE. MARIE.—The Edison Sault Company is to spend $75,000 in improvements this year.

MR. W. O. KNUDSEN has opened a branch office at Cleveland, O., in behalf of the Electric Storage Battery Company, and has his quarters at 914 New England Building that city. He will have the greater part of Ohio and Western Pennsylvania and part of New York State in his territory.

SOUTHERN NOTES

BRISTOL GAS AND ELECTRIC LIGHT COMPANY, of Bristol, Tenn., has recently installed a 200 h. p. Ball cross compound condensing engine, built by the Ball Engine Company, Erie, Pa.

HAGERSTOWN, MD., has voted through its city council $60,000 for a municipal plant, and has asked estimates and plans from the Westinghouse Company.

WHEELER ELECTRIC MANUFACTURING COMPANY, Chattanooga, Tenn., is now, it reports, running full on the Wheeler dental engines, and has a lot of orders on hand.

BARDEN-SHEETS ELECTRIC CONSTRUCTION COMPANY, of Houston, Tex., has recently filed a chattel mortgage for the benefit of creditors to the amount of $3,034, including Washburn & Moen, Electric Appliance Company, General Incandescent Arc Light Company, Central Electric Company, New York and Ohio Company, Interior Conduit and Insulation Company, Western Electric Company.

PHILADELPHIA NOTES

WASHINGTON CARBON COMPANY are doing a rushing business with their enclosed arc light carbons for both alternating and direct current. Several arc lamp manufacturers have adopted them for exclusive use.

MR. MARTIN E. HERSHEY, the well-known manager of the Foundry and Machine Works, East Harrisburg, Pa., has tendered his resignation. He has been connected with this concern for more than 15 years, during which time its product has become celebrated throughout the world. Mr. Hershey is a practical machinist, draftsman and thorough man of business.

KEYSTONE ELEC. INSTRUMENT CO., Ninth street and Montgomery avenue, Philadelphia, have appointed Mr. W. R. Garton their Western representative, with headquarters at 414 Ashland Block, Chicago.

NEW ENGLAND NOTES

MORSE WOOL TREATING CO. have just completed at Norton, Mass., an extensive plant for purifying wool. The buildings are of a very substantial character, entirely fireproof, and were designed and built by The Berlin Iron Bridge Company, of East Berlin, Conn. The floors throughout the whole plant are of beams and corrugated iron arches, to carry the excessive loads common to warehouse construction. The roofs are of the well known Berlin Iron Bridge Company's patent anti-condensation corrugated iron.

HOLYOKE, MASS. The city and the local company cannot agree as to the price of the private plant, under the terms of the municipal ownership act, and will take the matter to the courts for settlement.

FOREIGN NOTES

CANADIAN PACIFIC RAILWAY is now experimenting with car lighting by means of a generator placed on the axle.

MEXICAN TELEPHONE COMPANY, of Mexico City, has been making a number of improvements in its service, changing over to metallic circuits, and has bought a quantity of cables, etc., from the Western Electric Company.

TORONTO, CAN., is discussing a double track elevated road system to be built by the Toronto Elevated Railway Company.

The Electrical Engineer.

Vol. XXV. APRIL 7, 1898. No. 518.

Electrical Transmission in Tanneries.

A FIELD into which the electric motor has been quietly entering the last few years, and about which very little has been said publicly, is that of tannery work. It will therefore surprise many to learn of the extent of electric transmission work in these places. That the plan of transmitting power by the means of wires and electric motors should recommend itself to tannery engineers is not surprising, however, in view of the fact that the machinery in a tannery which is arranged for the most convenient handling of materials is necessarily scattered over a large area. A little power is wanted in one place, a little in another, and so on. To transmit power with shafting means either an immense amount of shafting or an inconvenient arrangement of the plant to accommodate the power transmission.

To the Northern Electrical Manufacturing Company, of Madison, Wis., is due the credit of being the first to fully appreciate the needs of the tanners of America for electric transmission, and to this company belongs the credit of being the first to fully equip with electric drive, including dynamos and motors, the first entirely electrically equipped tannery in the world. The engineers of the Northern Company have for some years back made a careful study of machinery used in the tannery trade, and have designed, built and placed upon the market a full line of enclosed motors built at special speeds for direct connection, so far as possible, to the tanners' machines.

One of the features of Milwaukee is the large number of tanneries operating there. The reason for the location of so many tanneries in that city is its nearness to the Wisconsin forests, which furnish the necessary hemlock bark, combined with its direct communication with the large stockyards and packing house centres of the West. The largest concern of the kind in the city and the first one to go extensively into electric power transmission was the Pfister & Vogel Leather Company, of which Mr. C. P. Bossert is the mechanical engineer. The economy this large corporation has found by the use of electric transmission is best shown by the extent to which it is using it in place of the old method of shaft and belt drive. Like many another concern, the Pfister & Vogel Leather Company was drawn into electric power transmission by an extension of its electric lighting plants to run a few motors in distant departments. The company have three tanneries at Milwaukee, all of which employ electric transmission as far as they were able to supplant shafting with it, and they also have a sole leather tannery at Cheboygan, Mich., which is now being equipped electrically throughout. The newest and most extensive of the three located in Milwaukee is the Bay View tannery, which covers about ten acres of ground. It can be imagined how much shafting and belting would be required to deliver power over this area by mechanical transmission. The generating plant at this tannery consists at present of a 100 k. w. generator belted from a shaft driven by the main engine. This engine was put in before electric transmission was thought of, and drives that part of the tannery adjacent to the engine room by means of shafting in addition to driving the dynamos. There is also being installed in this engine room a 60 k. w. direct connected Northern generator. The voltage employed is 250 to 240 volts at the switchboard. For lighting purposes three 80-volt lamps are run in series, as this answers the requirements around a tannery very well. From the marble switchboard, which is the work of Julius Andrae & Sons Company, Milwaukee, Wis., the current is distributed through the various parts of the plant by feeders to centres of distribution.

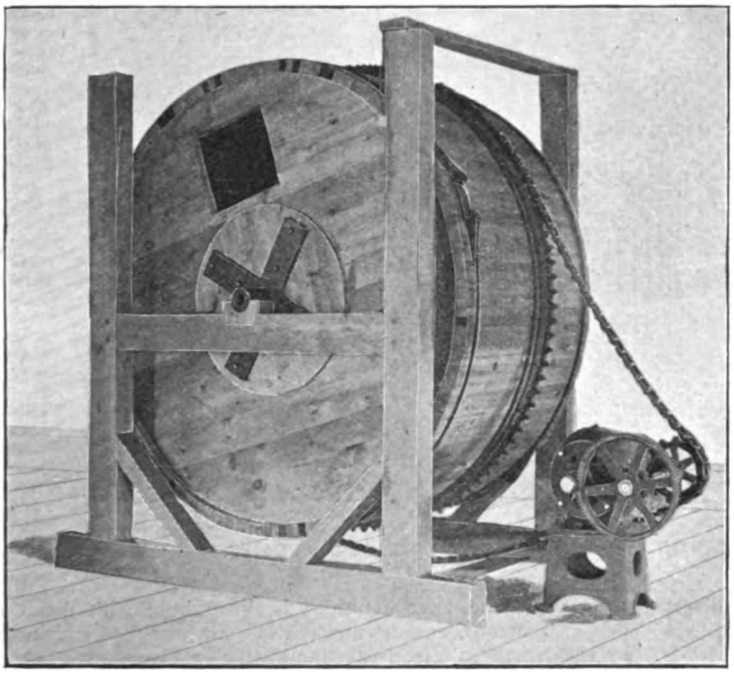

FIG. 1.—NORTHERN STEEL MOTOR, DRIVING RE-TANNING OR STUFFING WHEEL. SPEED, 18 R. P. M.

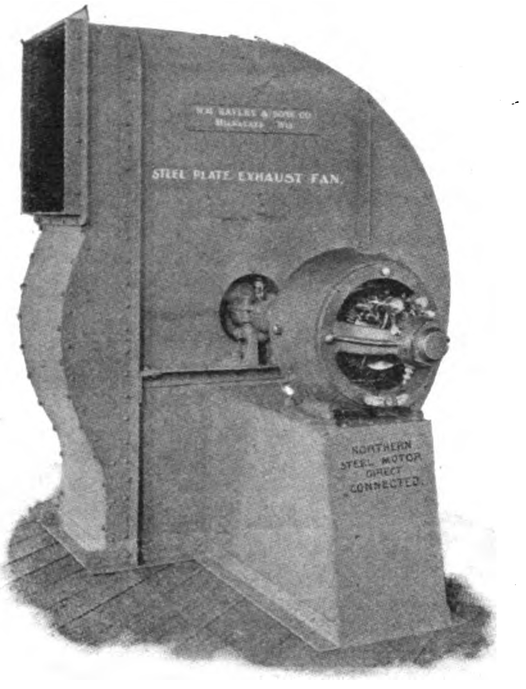

FIG. 6.—LEATHER VENTILATING BLOWER WITH DIRECT CONNECTED MOTOR.

The fluctuations of the motor load in this tannery are not very great, although they are rapid within a small range, as shown by the station ammeter. Thus, at the time of the writer's visit, the load was varying rapidly between 400 and 450 amperes, but rarely went above or below those limits.

Distributed over the plant are motors as follows: One 15 h. p., driving leach house pumping machinery; one 40 h. p., driving sole leather finishing department; one electric elevator motor worm geared to the winding drum; two 18½ h. p. motors direct connected to fleshing machines; one 40 h. p. motor, driving paddles and wash wheels; one 5 h. p. motor, belted to a leather press; one 10 h. p. motor, belted to wash wheels and pumps; three 7½ h. p. motors, each direct connected to a tanning drum; one small motor, driving a portable device for running hides from piles into the lime vats; one 5 h. p. motor, direct geared

to a triplex water pump and provided with a device whereby it is automatically started and stopped by a float in a tank which operates the rheostat by means of compressed air; one 40 h. p. motor, running the shavers and splitters and scouring departments, which departments have a capacity of 400 sides of harness leather per day; one 7½ h. p. motor, driving the line shaft to the jacks in the blackening room; one 5 h. p. motor, driving the finishing room jacks; one 18 h. p. motor, driving the stuffing department; one 5 h. p. motor, driving the sole cutting department. This completes the present electrical equipment of the tannery at Bay View.

The next plant in order from the electrical engineer's standpoint, will be the "Menominee," at Oregon street and First avenue, where are also the Pfister & Vogel main offices. This is an older plant and the work is more concentrated than at Bay View. The generators at this place are also belted from a line shaft, from which a part of the tannery is driven, as the electric power transmission here is a direct outgrowth of the lighting system. For the same reason 110 volts is the pressure employed. There are two generators, one 60 k. w. and one 35 k. w. In this tannery, as in the Bay View tannery, the motors are applied to the various driven machines with particular reference to the habits of the plant and economy in operation, that is to say, some of the heavier machines are operated by direct connection of motor to each machine separately, while others of the lighter running machines are arranged in groups according to the character of work they have to do, each group being driven from a short line shaft by one motor attached to said shaft. The great advantage of direct drive is shown very forcibly in the case of fleshing machines, which require heavy power at times and which always have been troubled with slippage of belts, thus retarding speed and causing not only loss of time, but an imperfect performance by the flesher. By the use of direct connection to this machine a constant speed is maintained and a considerable increase in daily output effected.

At this "Menominee" tannery the following motors are in service: Two 15 h. p. motors, driving each three bark hoists or conveyors; one 5 h. p., driving the experimental laboratory tannery; one 40 h. p. motor, running a six-story currier shop; one 15 h. p. motor, running the currier shop elevator; one special slow speed 10 h. p., direct connected to belt knife splitting machine; one 25 h. p., direct connected to fleshing machine; one 35 h. p., running eight small tanning drums; one special direct connected motor, running a 42-inch ventilating fan; one motor, driving a 36-inch ventilating fan; one 40 h. p. motor, to take the place of a steam engine in case of emergencies.

At the "Island Tannery" of the Pfister & Vogel Leather Company there is a small but economically important transmission. In the engine room, driven from the shaft, is a 45 k. w. 110-volt generator; 400 feet away is a 40 h. p. motor, driving a department and making a great saving over what would be necessary to drive a line shaft that length.

This company is now engaged in electrically equipping its sole leather tannery at Cheboygan, Mich. The Northern Electrical Manufacturing Company has the contract for the electrical apparatus and it is now being put in. The generator will be 75 k. w., 240 volts, and motors will be distributed as follows: One 10 h. p. motor, to run machine shop; one 10 h. p. motor, running carpenter shop; one 30 h. p. motor, driving leach house and pumps; one 25 h. p. motor, running wash house; one 20 h. p. motor, running sole leather finishing department; one 5 h. p. motor, driving an air compressor 1,000 feet from the engine room. It is also expected to put in some kind of an electric tramway for carrying goods around the tannery.

In addition to the Pfister & Vogel tanneries at Milwaukee a number of other Milwaukee tanners have adopted electric drive to a greater or less extent, according to their needs. Notably among these is A. F. Gallun & Sons and the Western Leather Company. The latter have recently erected a large addition to their plant and have equipped it throughout with direct connected dynamos, engines and motors, all furnished and installed by the Northern Electrical Manufacturing Company.

A number of tanners outside of Wisconsin have also adopted electric drive. The largest and most complete electrically equipped tannery in the United States is that of E. C. Fisher & Co., Salamanca, N. Y., the entire equipment of which was designed by the Northern Electrical Manufacturing Company, and all of the electrical machinery was built and installed by them. The plant is operated by two 75 k. w. direct connected dynamos and one 40 k. w., with about 50 motors, the majority of which are direct connected. The Northern Company has also installed electrical equipments for several other Eastern tanners.

The accompanying illustrations show the methods practiced by the Northern Electrical Manufacturing Company for equipping various tannery machines, and the purposes of said machines, are as follows:

Fig. 1 represents a stuffing wheel, into which the leather is put at a certain stage and mixed with grease and steam. The hides are revolved in this a certain number of moments one way and then the drum is reversed and run again in the opposite direction, thus completely filling the leather with oil and at the same time untangling it. Fig. 2 is a large Vaughn fleshing machine, direct connected to special Northern motor. The pur-

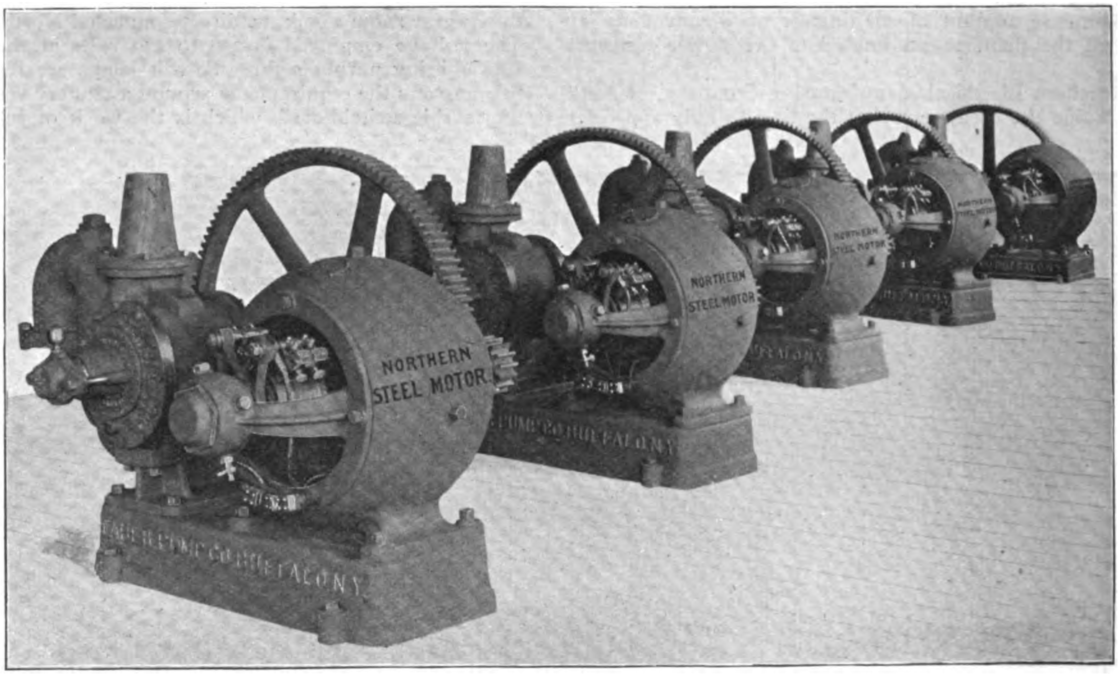

FIG. 7.—NORTHERN MOTORS DRIVING A GANG OF TABER LIQUOR PUMPS.

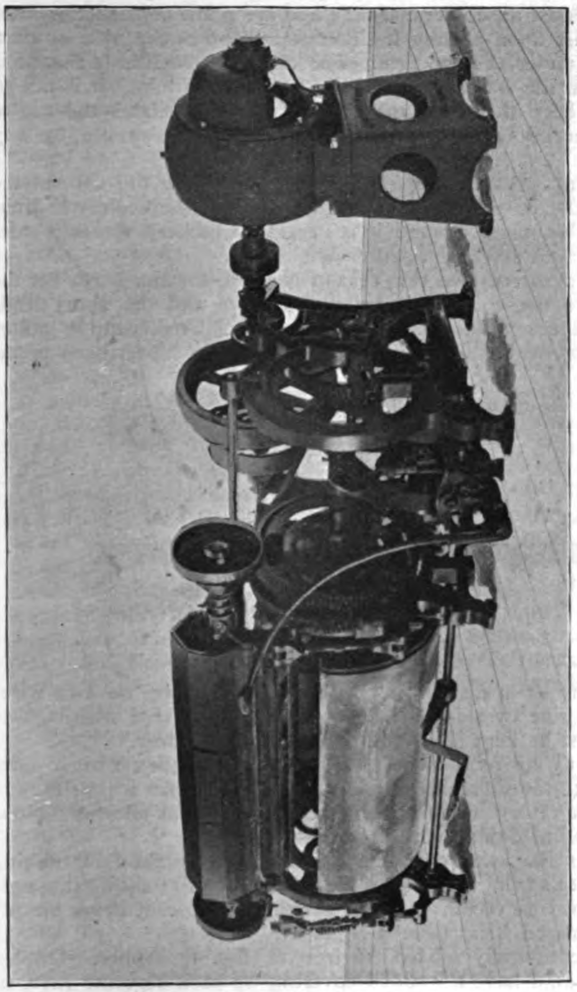

FIG. 2.—NORTHERN STEEL ENCLOSED MOTOR, DIRECT CONNECTED TO LARGE VAUGHN FLESHING MACHINE.

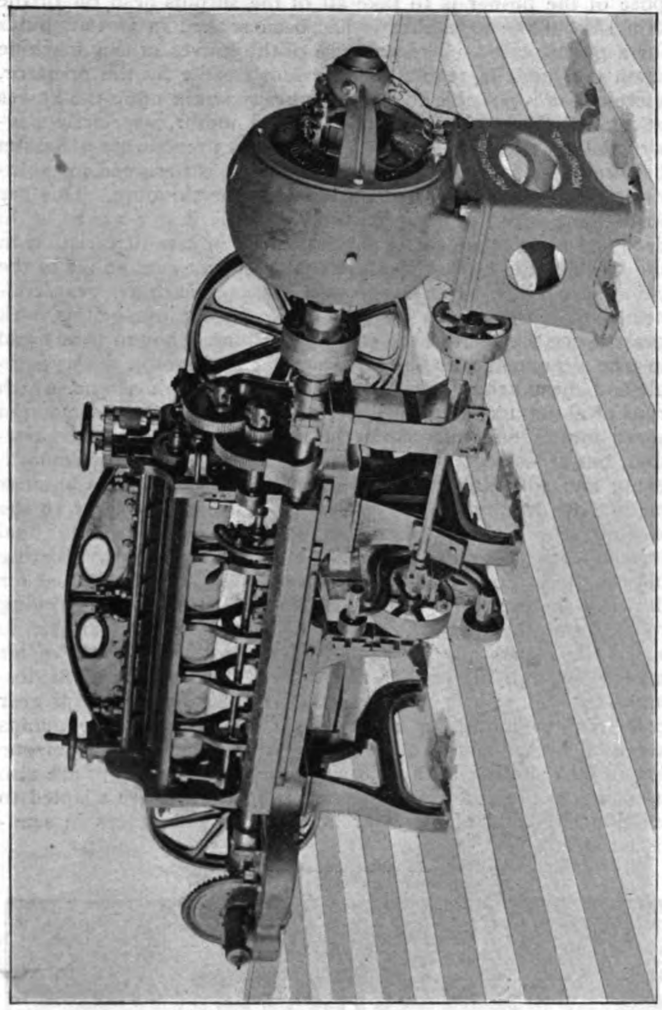

FIG. 3.—NORTHERN STEEL MOTOR, DIRECT CONNECTED TO BASSETT BELT KNIFE SPLITTING MACHINE.

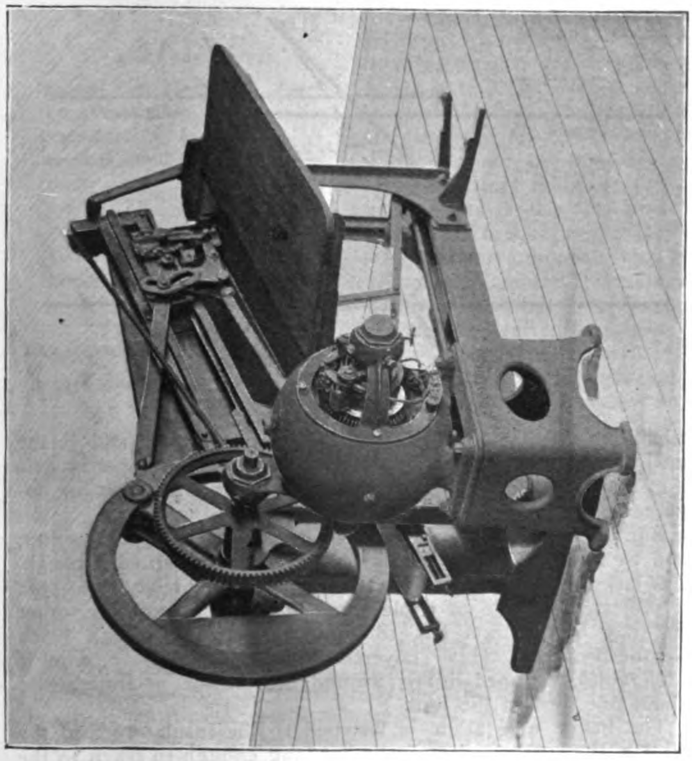

FIG. 4.—NORTHERN STEEL MOTOR, VARIABLE SPEED ATTACHMENT, DRIVING BAKER STAKING MACHINE.

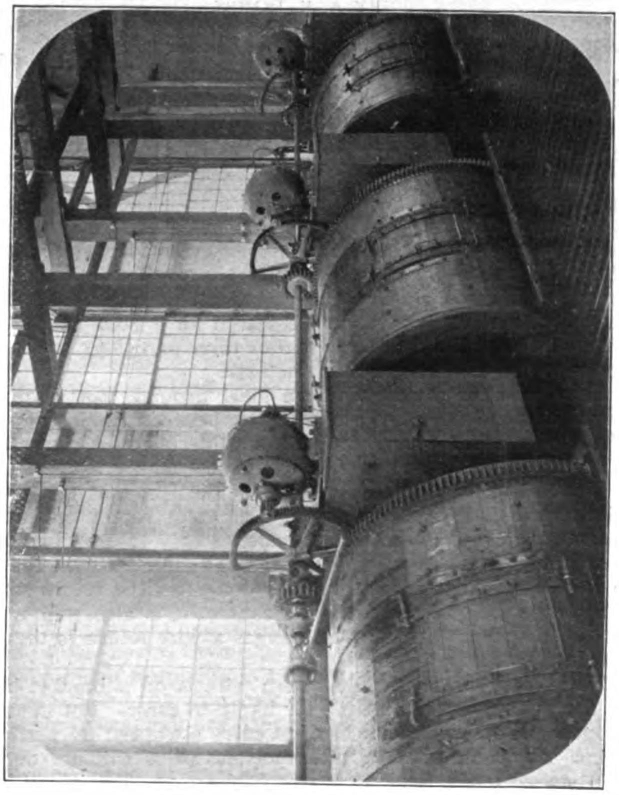

FIG. 5.—TAN DRUMS ELECTRICALLY DRIVEN BY NORTHERN MOTORS.

pose of the flesher is to take all of the surplus flesh off of the skin side of the hide after it has been soaked in various fluids for a given period. The pressure of the knives of this machine upon the hides is regulated by a foot treadle by the operator, therefore it is possible to put very heavy strain upon the knives at times and requires a very powerful motor, especially constructed, to take care of this strain. Fig. 3 represents a Bassett belt knife leather splitting machine, which is designed for splitting thick hides into two or three, also for skinning. This has to be done with the greatest nicety and the motor has to be so designed as to take care of varying speed in case of variation in the stock of the leather in order that there may be no jar in the cut of the knife. Fig. 4 shows a staking machine, gear connected to Northern back gear motor. By the use of this back gear device the shaft of the staking machine is bound firmly and in true alignment with the armature shaft of motor, a very simple and cheap arrangement, whereby the staking machine, which runs at about 100, is propelled with a moderate priced medium speed motor, effecting about the same result as direct connection, but at less cost. The staking machine is used for smoothening and softening out the leather. Fig. 5 illustrates another method of driving tan drums, which are used similarly to the stuffing wheel, except that they are filled with tanning fluid instead of with grease. In Fig. 6 is illustrated a ventilating blower direct connected to Northern motor. This is used for drawing the air through the leather as it hangs in the drying rooms, and the motor is so constructed as to be variable in speed, thus enabling the tanner to control the volume of air moved through his leather and thus control the speed of drying at his will. Fig. 7 shows a gang of Taber liquor pumps gear connected to motor, all mounted on one base. These pumps are used by tanners in pumping their tanning fluids from one location to another in their leach houses. These pumps are also used in glucose factories and soap factories and are adapted to moving any kind of liquid or heavy soapy substances in semi-liquid form.

TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work.—IV.

BY A. E. DOBBS.

LINES AND CIRCUITS.

IN exchanges of less than 1,000 subscribers metallic circuits are not necessary, a common return answering every practical purpose.

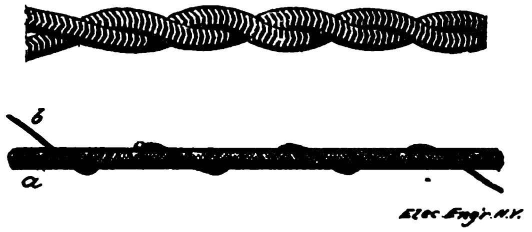
In some small country towns, grounded lines will answer, but a return wire is generally preferable, for, with lines grounded to gas and water pipes and driven rods, the resistance of the "ground" and therefore of the line is a very uncertain quantity. Rods especially are a nuisance in this regard. The author remembers cases where telephones, even grounded in the bottom of a well, had their talking qualities improved 100 per cent. by being connected on a direct return to the office. Then there is no working time saved if, in the search for a good ground, the wireman has to bore through two or three partitions or through floors to the cellar, as is often the case.

Even where a water pipe, an ideal ground, can always be found electrolysis will often be set up between the lead or iron of the pipe and the copper wire, for soldering such connections in private houses is not feasible, and such connections need more or less inspection, to say nothing of the fact that the ground wire running, as it does, through different rooms or through cellars, is often broken. It is almost as easy to drop two wires from a pole line as one, then put a single hole through the wall or window casing and the work is done, and the return service can always be relied upon. Of course, it is also well understood that where a trolley line exists a wire return is the only satisfactory one.

The proper place for the return wire is on a bracket below all the arms that the pole is ever likely to carry. For example, suppose that the line may have to carry six arms; by putting it below where the sixth would come the wires will not only be well spread out in making house connections, but it will serve to protect the line against too close familiarity on the part of other companies and hold a clear right of way for these six arms against all comers. Still there are good construction men who insist upon putting it either at the top of the pole or on a bracket under the top arm. The objection to this is that it is always in the way and in making drops to buildings it is not so easy to keep the wires apart, and often necessitates the use of porcelain knobs on the arm, which is not desirable by any means.

The only reason ever heard given for having the wire at the top of the pole is that in neighborhoods where electric light and trolley wires abound it is necessary to keep the two sides of the circuit as close together as possible.

We fail to see that this reason is valid, for the wires on the poles are not free from trolley influence and the short leads to the house connections, if carefully insulated, cannot gather up a great deal of noise, and if the lead to the subscriber's premises is any great distance from the main pole line, the two wires will run side by side anyhow, and unless insulated wire is used they must be kept far enough apart to keep "clear."



FIGS. 11 AND 12.

In many towns it is best to use twin or duplex wire in connecting to the subscriber's premises, but even then it is as easy to catch the return wire on one part of the pole as another. Now, a word as to duplex wire.

This is the most convenient and sightly method of making connections from the pole to the house. Fig. 11 shows the style of duplex wire commonly used for this purpose, it being simply two insulated wires twisted together.

It is commonly of No. 16 iron or No. 14 copper. Duplex wires should have a braided covering on each separate wire, as plain rubber covered wire, often used for this purpose, means constant trouble, except, perhaps, in offices where it is not exposed to the weather and can be constantly inspected.

The style shown in Fig. 11 is used almost entirely by some telephone companies in making house connections, and is the only kind to use in going through trees, but it frequently gets into trouble from the wires chafing each other and coming together.

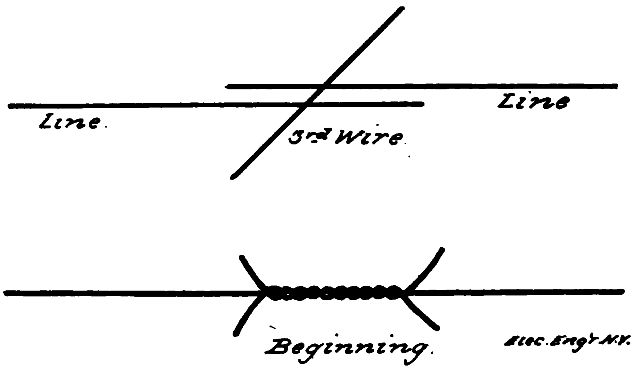


FIG. 13.

Fig. 12 shows a form used with great success by the writer, and we have yet to find the first one chafed or burned through. The large wire (a) is simply a No. 14 iron wire, or No. 12 copper if preferred, double or triple, braided weatherproof; the other (b) may be common No. 18 annunciator wire (though black weatherproof or rubber covered and braided No. 18 wire is preferable), wrapped lightly around the outside, at the rate of about one turn to the foot.

The heavy wire alone is fastened to the insulators and the ends of the smaller wire can be left long enough to reach to the instrument without a joint and to reach the line wire at the other end, leaving that side of the line free from joints. Two

men can make one of these in a few minutes. The advantage in using this latter form lies in the fact that the smaller wire, lying lightly outside the other, being drawn only tight enough to keep it from sagging, does not chafe or wear the insulation.

The Simplex Company of Boston advertised something like this some years ago, but with this difference, that the centre wire was copper while the outside one was steel. I am inclined to think that the steel wire on the outside, though theoretically better, would be more troublesome in practice, on account of chafing through, but having never seen the wire, of course, I can't say.

But to come back to the subject of the common return wire. This should generally be of copper, though sometimes it is desirable to use iron wire to stiffen the pole line, but where iron is used have nothing smaller than No. 8 for leads carrying not in excess of 20 wires, while for leads carrying not in excess of 35 wires two No. 8 or one No. 6 will do. If two iron wires are used keep them separate, distribute the load as near equally as possible on each, run them side by side and transpose every few poles. In this way cross talk will be reduced to a minimum. Note: If iron wire is used to stiffen the line extra heavy brackets will have to be used and at least one lag screw instead of nails to fasten them on. But, still, its superior conductivity and absence of self induction put copper away ahead of iron for this purpose.

All joints should be carefully made, and in order to reduce resistance to the lowest possible point, soldered. It is true that copper joints known as the "3-wire" splice show a very low resistance, being only from .004 to .012 of an ohm (see Electrical Engineer, November 18, 1897). But a little carelessness may increase this resistance and even one extra ohm may increase the cross talk very materially.

In soldering copper use a heavy iron or a blow torch with a small concentrated flame and solder only in the centre of the twist, and do not leave the heat on any longer than necessary, and do not heat outside the joint, as heat will soften and weaken the line. Thus a joint can be made that is electrically and mechanically perfect.

Soldering is not necessary in the drop from the lead to the subscriber, nor is it necessary to solder wire smaller than No. 10 B. & S. All copper lines should be made with what is known among linemen as the "3-wire" splice. This is made by splicing in an extra piece of wire, as shown in Fig. 13, after which it is finished the same as any other twist joint. This is much stronger and better than the ordinary telegraph splice.

Steam Railway Use of the Telephone.

NOTICE.

Take down Receiver and ascertain whether line is in use BEFORE RINGING.

F. E. NOW,
Sup't Telegraph.

THE Cleveland, Lorain and Wheeling Railway Company, a great coal carrying road in Eastern Ohio, of which Mr. F. E. Now is superintendent of telegraph, has installed and is now operating two telephone circuits, the length of each being over fifty miles, on different parts of its road. Mr. Now was one of the first superintendents of telegraph to appreciate the great value of telephonic communication, in addition to telegraphic service, between offices, and that his company thinks well of his ideas is shown by the fact that two circuits have been installed so far.

The circuit which Mr. Now last built reaches along the road from the general offices at Cleveland to the great coal wharves of the company at Lorain, a distance of fifty-four miles, with seven intermediate stations bridged in on the line. Leading out from Cleveland the line takes two conductors in the underground cables of the Cleveland Telephone Company for a distance of about two miles; the rest of the way the line extends overhead. That part of the line which is overhead is placed on poles of the Western Union Telegraph Company, and consists of two bimetallic wires of size No. 12, Brown & Sharpe gauge. The wires are attached to the cross-arms by means of porcelain knobs and are transposed every one-seventh mile, or thereabouts. The apparatus used is leased from licensees of the American Bell Telephone Company, the Cleveland Telephone Company and the Central Union Telephone Company, the railway line running through the territory of each licensed company. The instruments are of the standard "Bell" type, "Blake" transmitters being used.

It will be readily seen that the conditions under which this circuit operates are rather severe, because of the number of stations on the line, nine in all, and the fact that the wires, for the greater part of the way, are in close proximity to many heavy telegraph lines. There is, however, practically no induction on the telephone wires from the telegraph lines, this because of the number of transpositions in the line, of the high grade of construction and of the use of bimetallic wire, which wire is rapidly becoming a standard for first-class telephone lines. In a few words, the workings of this circuit may be said to be highly satisfactory, in fact, no better telephonic circuit can be found.

The Cleveland, Lorain and Wheeling Railway Company does not use its telephone lines for dispatching trains, but rather for the hundred and one important matters which naturally come up in conducting a busy road. The telephone and the telegraph each has its own sphere; if anything, the telephone has reduced the amount of correspondence between offices.

A most ingenious, ingenious because it is remarkably simple,

MR. F. E. NOW.
(Supt. of Telegraphs, Cleveland, Lorain & Wheeling Railway Co.)

system of calls, or signals, has been devised by Mr. Now, this being necessary because all stations are bridged in on the line, and when one office calls another the bells at all stations are actuated. The object in view, of course, when arranging this system of calls was to have each signal so that it would be readily distinguished from all others, and, from the card shown above, which is placed at all stations, it will be seen that this has been accomplished.

Mr. Now has spent many years in telegraphy and has devoted much time and study to general electrical subjects. The results of his study are apparent in several important inventions relating to the telegraph, one in particular, his invention for simplifying office equipment, having been most favorably received. Though his work in telephony is of comparatively recent date, the way in which he has constructed and equipped his telephone lines shows a thorough understanding of the subject. In addition to his duties as superintendent of telegraph, Mr. Now is also purchasing agent of the Cleveland, Lorain and Wheeling Railway Company.

MECHANICAL

Successful Tests of the Wright Wave Motor.

NO one who has ever studied the wave movement of the ocean has failed to realize that millions of horse power were being daily wasted upon the beach along the various coasts of the country. The harnessing of this mighty power of the ocean waves and transforming it into a steady, constant, mechanical power available to drive the machinery of the world, has been the dream of the inventors of the century. The great problem has been how to change the unsteady, intermittent power of the waves into a steady, constant power required for the operating of machinery, and at the same time to prevent destruction of the plant during periods of storm. To accomplish this purpose many devices have been invented year after year, but most of them have proved utter failures, and have never passed beyond the experimental stage. The Wright wave motor, which we describe and illustrate below, is one of the recent promising attempts. As a matter of history, it may be interesting to state that the Los Angeles Ocean Power Company built its first experimental wharf in January, 1897, and public tests were made soon after in the presence of many witnesses. Encouraged by the results of these tests, the company was organized in March the same year. Soon after, the company expended $2,000 to extend and enlarge the plant already commenced. The wharf, a good metallic structure, shown in Fig. 1, was extended out to about 350 feet into the ocean and 26 feet in width. At the outer end of this wharf, a wave motor plant was installed, consisting of three floats and other necessary machinery to store, equalize and regulate the power obtained.

This plant has been subjected to a working test of over thirty successive days, during which time, from November 16 to December 16, 1897, very severe weather and rough seas were encountered, storms which wrecked a vessel within sight of the wave motor plant, and did other damage. The results of these tests are given in the following table:

RESULTS OF PUBLIC TESTS MADE WITH THE WRIGHT WAVE MOTOR AT POTENCIA, CAL.

DATE.	No. of waves per min.	Piston travel in feet per minute.	Average pressure, pounds per sq. inch	Cubic feet water per minute discharged per float.	Horse power per float developed at Pelton wheel.	No. of electric lights.	Condition of sea and weather.
December 1..	8	12.5	150	3.8	2.3	9	Stormy.
December 2..	7	14	152	3.9	2.5	9	Rough.
December 3..	4	16	155	3.7	2.3	9	Calm.
December 4..	5	14.5	155	4	2.9	9	Calm.

December 14..	6	18½	195	4.25	3.3	9	Stormy
December 15..	7	15.5	180	3.8	2.5	9	Calm.
December 16..	6	14	175	3.2	2.3	9	Calm.

The electric lights were merely to demonstrate steadiness of power. Proportional variations were due to varying conditions under which the motor was tried. Variations in pressure were due to changes in weight of floats and size of nozzles, and amount of water pumped, etc.

The motor is operated by a series of floats operatively connected with vertical hydraulic compressors, or pump cylinders which are in turn connected with a large storage pressure tank of heavy steel. The rising and falling movement of the waves raises and lowers these floats, and in doing so, pumps fresh water from a reservoir into the pump cylinders and forces it into the storage pressure tank, where by compressing the air contained in the tank the water becomes subjected to a very heavy pressure, under which pressure it is driven out of the tank through a nozzle with terrible force upon the buckets of a Pelton water wheel, which it drives at a high speed, and to

FIG. 1.—PERSPECTIVE VIEW OF PIER, SHOWING TWO FLOATS IN POSITION.

which is attached a dynamo or other machinery intended to be operated. From the Pelton wheel the water drops back into the reservoir from which it was originally pumped, and the same water is thus pumped over and over again without waste and requiring no new water supply. The pressure tank feature

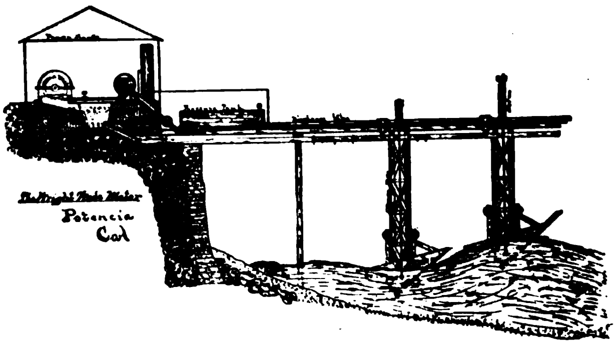

FIG. 2.—SIDE VIEW OF POWER HOUSE AND SECTION OF WAVE MOTOR WHARF, SHOWING TWO FLOATS.

of the invention serves to drive a water wheel by water with the same effect obtained by a water power under a high gravity head, but it reverses the old maxim that "the mill will never grind with the water that has passed," for that same water is again put under pressure and used as an endless chain to com-

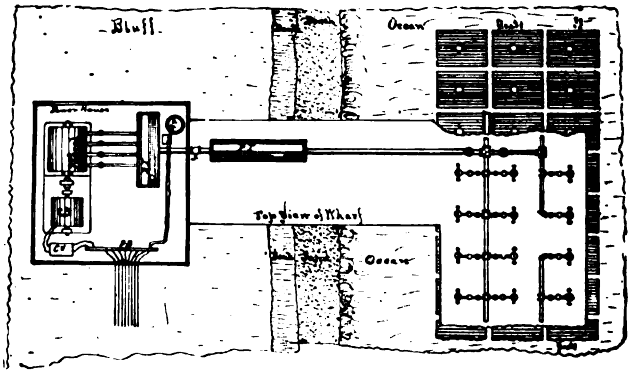

FIG. 3.—TOP VIEW OF POWER HOUSE, APPROACH WHARF, AND WAVE POWER PLANT.

pel continuous revolutions of the water wheel, and hence continuous, steady power for the generation of electricity.

But not only does the pressure tank serve to put the water pumped under heavy pressure proper to drive the water wheel, but it stores and equalizes the power from wave to wave, and

in addition furnishes an absolutely reliable automatic means of regulating the power created, so that during periods of excessive wave movement, as occur in storms, no more than a given amount of power can be created—for the spirit of the living creature seems to actuate this mechanism, so that during times of danger it practically furls its own sails as it were; this is done by the accumulated pressure in the pressure tank exerting itself upon the pump pistons, so as to offset the weight of the floats tending to draw such pistons down.

In the working wave motor plant the following is the method of construction and installation:

A wharf running at right angles to the beach has been constructed, running out to a point where the best average wave movement is obtainable; that is, to a point about where the swells usually begin to break, from which point a wharf with metallic piling is being constructed, running parallel to the beach and following along the line of the best average wave movement. Each of the piles will be of iron beams and will serve as a guide for the float; and attached to the wharf, side by side, and facing the ocean, and three or more deep, the motor floats will be installed. To this wharf will be attached merely the motor floats and the pumping mechanism; one hundred or more pumps and floats will be connected by supply and suction pipes with one pressure or storage tank, which with the water wheel will be located and installed upon the high bluff on the beach in the power house, where the entire electricity generating plant will be located. Thus the reciprocating action of a great number of floats, distributed over a large area of ocean frontage and pumping into one storage tank, will, of itself, largely equalize the power delivered to the pressure tank. Side and top views of the power house, wharf and wave motor plant are shown in Figs. 2 and 3 respectively.

On the 8th of February additional tests were made with two floats in operation, which developed 8.6 h. p. The plant is small at present, but has been running an electric generator continuously since last September. The plant will soon be enlarged to 200 h. p. and a transmission line will be built to Redondo, a distance of four miles, to which current will be furnished for light and power purposes. All this would appear to show that the apparatus has passed the experimental stage and is doing solid, commercial work.

ELECTRIC TRANSPORTATION

The All-Day Efficiency of Elevated Motor Cars.

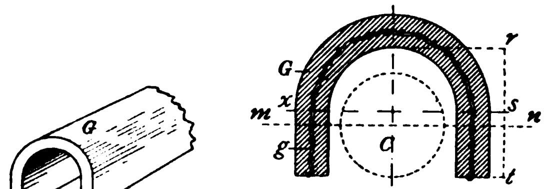
BY J. R. CRAVATH.

THE multiple unit system for elevated roads has had the point urged in its favor that its efficiency is higher than systems employing single motor cars or electric locomotives during light load hours when only two-car trains are to be run. Thus it has been claimed that since the electric locomotive or motor car used on an elevated road must be large enough to handle the longest trains that are ever run on the road, it must necessarily be working very much below its economical load when running a short train. At first thought this seems plausible. Superintendent W. E. Baker of the Metropolitan West Side elevated railroad of Chicago has recently called the writer's attention to the fact that under existing conditions of practice it is easily possible to make the efficiency as high on light trains as on heavy when single motor cars are employed. The time table of an elevated road is usually so arranged as to require the same schedule speed whether the trains be light or heavy. When the trains are heavy, the practice usually is to accelerate as fast as the heating of the motors will permit, and after getting up to speed keep the current on until it is time to apply the brakes. Now, if it is desired to keep the motors operating with the same efficiency with light as with heavy trains, it is only necessary to work them at the same rate during the time that current is turned on, allowing them to drift with current off during the balance of the time. Thus with a light train the controller can be worked so as to take the same current during acceleration as with the heavy train. The acceleration will then be quicker and a slightly higher rate of speed will be attained, but as soon as speed is attained current can be shut off and the train allowed to drift until it is time to apply the brakes. The theoretical efficiency of this latter method is higher than the former (see Mr. Steinmetz's discussion of M. H. Gerry's paper in October number Transactions, A. I. E. E.), so that the efficiency is, if anything, higher with the light than with the heavy train, due to the drifting that is possible in practice, if the right methods are employed. The single motor car system has also the advantage of having less weight to be moved than if motors are scattered through the train, so that the multiple unit system gains nothing on that score, except with two-car trains, where the weight is about equal for the two systems.

The single motor car system may be old, but it is not entirely bad after all. The only other point made against it for elevated work is that it does not allow sufficient traction for accelerating a long train, but it is noticeable that few companies can be found that care to pay for a higher acceleration rate than a single motor car affords.

The Sewall Conduit on the Chicago City Railway.

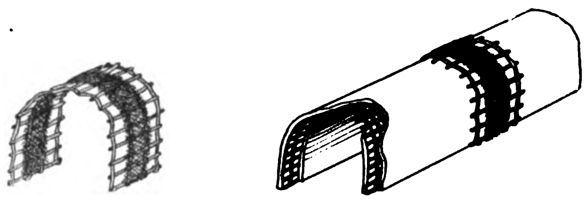
IT is notable that but few forms of conduits for carrying underground cables have ever been found a commercial success or won universal favor. An addition to the successful list seems nevertheless about to be made by C. H. Sewall, of Chicago. Mr. Sewall has been studying conduits for some time and now has a system that is entirely practical and has some decided advantages over others. A short stretch of this conduit was laid some time ago by the Chicago City Railway at Thirty-ninth street and Michigan avenue. Cables have been drawn through it now for a year, and it is giving satisfaction, although



FIGS. 1 AND 3.—DETAILS OF SEWALL CONDUIT SHOWING SHAPE OF DUCT AND IMBEDDED WIRE LATHING.

it was the first laid and many improvements in details have since been made.

The conduit consists essentially of ducts formed of cement arches, Fig. 1, embedded in concrete, as shown in Fig. 2. The cement arches are made to accommodate cables of any size specified (usually 3 inches) and the thickness of the arch walls is from 3-16 to ⅜ of an inch. They are made of a mixture of 50 per cent. Portland cement to 50 per cent. sand. Embedded in the cement of the arch is a wire lathing composed of iron wire .035 inch in diameter and with meshes ⅜-inch square, as shown in Figs. 3 and 4. This wire cloth performs a most important part in strengthening the arch. The arches are made by spreading the cement over a core. The lathing helps hold the cement



FIGS. 4 AND 5.—DETAILS OF SEWALL CONDUIT SHOWING IMBEDDED WIRE LATHING AND THE JOINT COVER.

together until it is hardened, which is in about seven days. The arches are made in 6-foot lengths for straight work. One great advantage of cement is that it does not warp in drying, and these arches, when completed and ready for use on the street, are as straight and true as the cores from which they were made. The arches being prepared the trench is dug and a concrete foundation of Portland cement, sand and broken stone is laid. On top of this foundation a smooth cement floor is spread and troweled to a polish. The arches, thoroughly wet, are laid on the floor under a template which gives them absolute positions. As the arches come from the molds exact in size and the work in the trench is done with accuracy, the floor being a perfect plane, the joining of the arches end to end is

easily made very accurate. As soon as work has fairly started on one tier of arches they are covered over at once and work is begun on a second tier; the process can be indefinitely continued as it is not necessary to wait for the cement to set. The joints between the arches are covered with wire lath and cloth to prevent concrete from falling through into the ducts during construction. The joint cover is shown in Fig. 5 and also in Fig. 2. The corners at the ends of the ducts are slightly beveled to prevent cutting the lead cable covering in case the ducts are not in perfectly accurate alignment. Where there are to be curves in the ducts, it is a simple matter to manufacture short curved pieces of duct of the proper radius, and these can be joined to turn any kind of a corner desired as shown in Fig. 6. The curves can be made long, short, reverse, or any kind needed, by joining these short curved sections.

The construction having been shown it remains to discuss its commercial advantages over other forms. The object of a conduit is of course to furnish a permanent duct or set of ducts which will allow the easy pulling in and out of lead-covered cable at all times, which will be strong enough to withstand all strains put upon it without interfering with the continuity of the duct and without offering rough or irregular duct surfaces to cut or bind the cable and collect sewage water. First, in the matter of alignment, it is evident that as the duct floor is jointless and perfectly plane, the cable rests on a surface which has absolutely nothing to abrade the lead or make it draw hard. Furthermore, the ends of the arches being made to exact size and laid to templet with corners slightly beveled there is but little chance for bad horizontal alignment. This means that longer lengths of cable can be drawn in than with other conduits. The same perfect smoothness of duct interior is maintained on curves.

By reference to the figures it can be seen that the arch form of duct is the one combining greatest strength with least resistance to pulling in the cable. The cable in the arched duct touches only three points, the floor and the two sides. In the round duct it practically rests over a considerable area on the bottom of the duct. A square duct is easy to draw through, but is deficient in strength as compared with the arch when the two are made for the same size cables. When we consider the amount of space taken up by the ducts there is no difference between the arch and the square or round ducts. As to durability of material in the Sewall conduit there is nothing exposed but hydraulic cement concrete, which is practically indestructible underground. The strength of this conduit structure is one of its good points. Concrete has greater compressive and tensile strength than terra cotta, and iron wire has the greatest tensile strength of any material. These two materials are combined in this structure and the result is that a much smaller cross section of material can be used for a given number of ducts.

In each arch there are twenty-two wires lengthwise with an aggregate tensile strength of 2,000 pounds, and thirty wires of the same size crossing them to every lineal foot of arch. In whatever direction the mass is strained, many wires will come into tension and resist. The fact that the arches and the concrete filling unite to make practically one mass adds to the conduit's strength over what it would be if ducts and filling were different material. The greatest element of strength in this conduit, however, is the fact that the floors are jointless and the duct joints are alternated so that at no one place is the conduit mass weaker than at others. The strength of any conduit is limited by its strength at its weakest points, viz.: the joints, and the Sewall construction makes it practical to distribute the joints and allow the surrounding mass to be made of less cross section than if the ducts were of another material. The floor being jointless there are no pockets to hold sewage as is sometimes the case with present conduits.

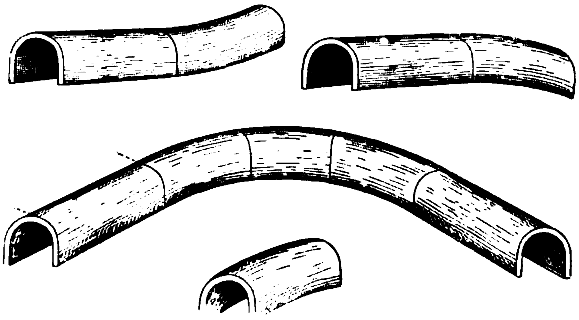


FIG. 6.—CURVED PIECES OF SEWALL CONDUIT DUCTS.

As no very expensive materials or processes enter into this construction of conduit, it can be laid at no greater cost than present forms.

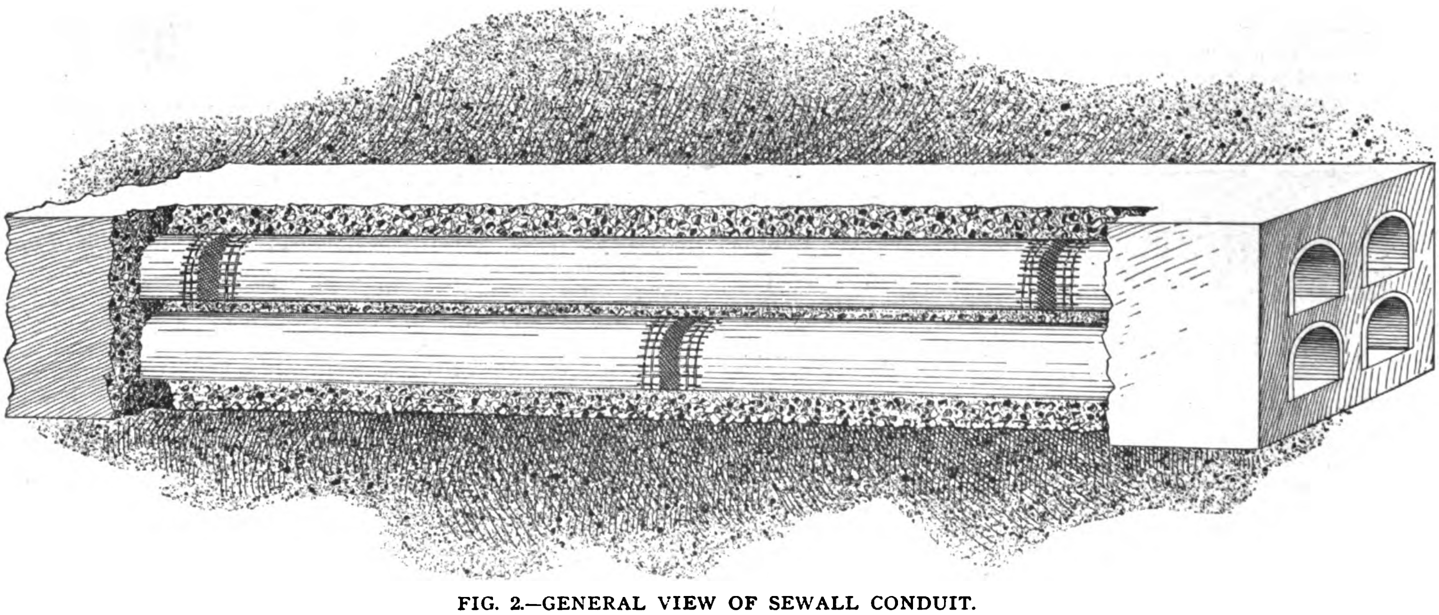

FIG. 2.—GENERAL VIEW OF SEWALL CONDUIT.

BRISTOL, CONN.—The Bristol and Plainville Tramway Company are erecting near Plainville, Conn., a new substantial steel bridge, having a span of about 90 feet. The bridge has been designed with a view of being a permanent structure, well able to take care of the increasing and heavy traffic of the road. It has been furnished and is now being erected by the Berlin Iron Bridge Company, of East Berlin, Conn.

BUFFALO, N. Y.—The Buffalo, Hamburg and Aurora Railway Company has sent out its plans and specifications to a number of general contractors, and bids for 19½ miles of construction, 1,400 h. p. generating plant, and car barns have been opened. Mr. U. L. Upson is secretary and general manager, Ellicott Square Building.

Heavy Electric Traction.—The Mason City and Clear Lake Road.

ALMOST immediately upon the production of a system of motors for heavy traction the Walker Company began to install them on many railroads. Among the latest recruits to the interurban railroad equipment with the Walker system is the Mason City and Clear Lake railroad, owned and operated by the Mason City and Clear Lake Traction Company. They have been successfully transacting some very heavy traffic electrically. In Fig. 1 is illustrated a motor car equipped with four 50 h. p. motors, arranged in pairs on bogie trucks. This car is used as a locomotive and its regular duty is to propel, at a speed of 30 to 40 miles per hour, a train of six 40-foot trailers, which are often heavily loaded with passengers. Fig. 2 illustrates this train at its regular work and gives a good idea of the character of the cars composing it.

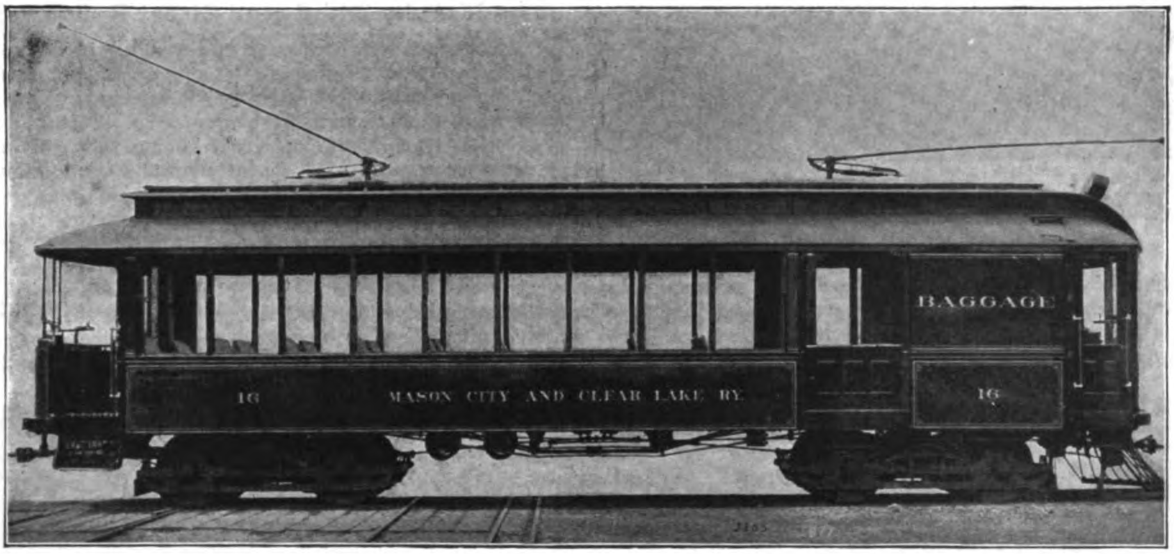

FIG. 1.—MASON CITY AND CLEAR LAKE MOTOR CAR EQUIPPED WITH FOUR 50 H. P. WALKER MOTORS.

This large car is frequently used for hauling short freight trains. It has handled eight heavily loaded cars without difficulty, and drawn them at a speed of 32 miles an hour, and the management of the railroad believes that it could handle ten and possibly more if occasion should arise. The heaviest grade on the road is 2 per cent.

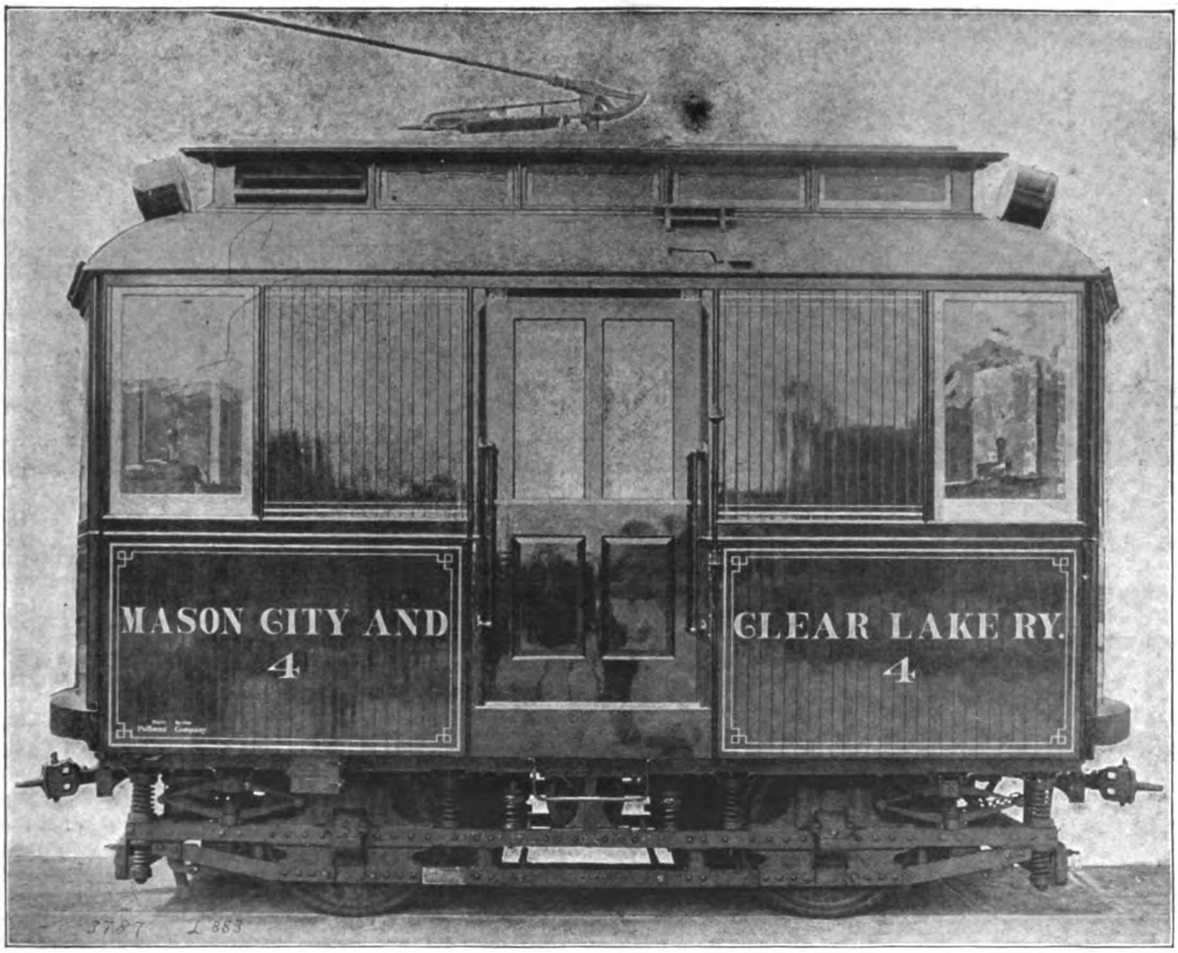

FIG. 3.—WALKER ELECTRIC LOCOMOTIVE, MASON CITY AND CLEAR LAKE RAILROAD.

In Fig. 3 is illustrated a Walker electric locomotive, in use

on the line. In external appearance it is not impressive as being a particularly powerful machine, but it carries on each of its car axles a 75 h. p. motor. Though its complete weight is but

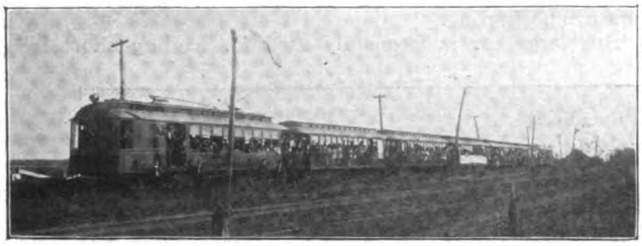

FIG. 2.—TRAIN EQUIPPED WITH WALKER MOTORS, SPEED 30 TO 40 MILES PER HOUR, MASON CITY AND CLEAR LAKE RAILROAD.

20,000 pounds, it can rapidly accelerate a train of six loaded freight cars, each of which is more than double the length of the locomotive that propels them. This locomotive, connected to a train such as it commonly hauls, is shown in Fig. 4. The Mason City and Clear Lake Traction Company have expressed themselves as very much pleased with the equipments, and it seems that they have put them to severe tests which justify the

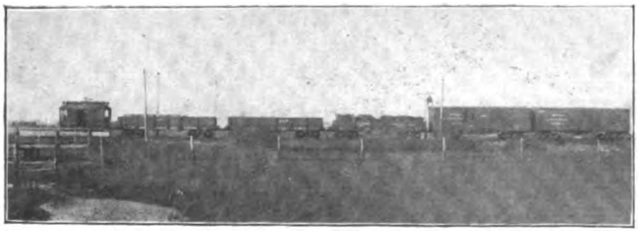

FIG. 4.—WALKER ELECTRIC LOCOMOTIVE CONNECTED TO A TRAIN OF CARS, MASON CITY AND CLEAR LAKE RAILROAD.

strong letters of recommendation which they have sent to the Walker Company.

The 50 h. p. motor is provided with the Walker patent suspension. There is absolutely no unnecessary dead weight on the axle and none of that weight can be considered as part of the motor. It consists merely of the gears and casing and axle bearings, the connections of which to the car axle are inevitably rigid. Both of these motors have been extremely popular in interurban work and are being largely sold.

The Murphy Third-Rail Street Railway System.

Ever since electric street railroading became established on a practical basis, some method of avoiding the stringing of overhead trolley wires has been sought for, and many have been the attempts to overcome it. Naturally, the first suggestion which presented itself having this end in view was to place the conductors in an underground conduit, and take the current from them by means of a plow, on lines quite similar to the old cable roads. The cost of such underground construction naturally deterred street railways from undertaking it, and even at the present day—more than twelve years after electric railroading has become an established branch of the art—New York City and Washington are the only places in the country where such underground roads have been put down. The old objection as to cost, therefore, still predominates, and

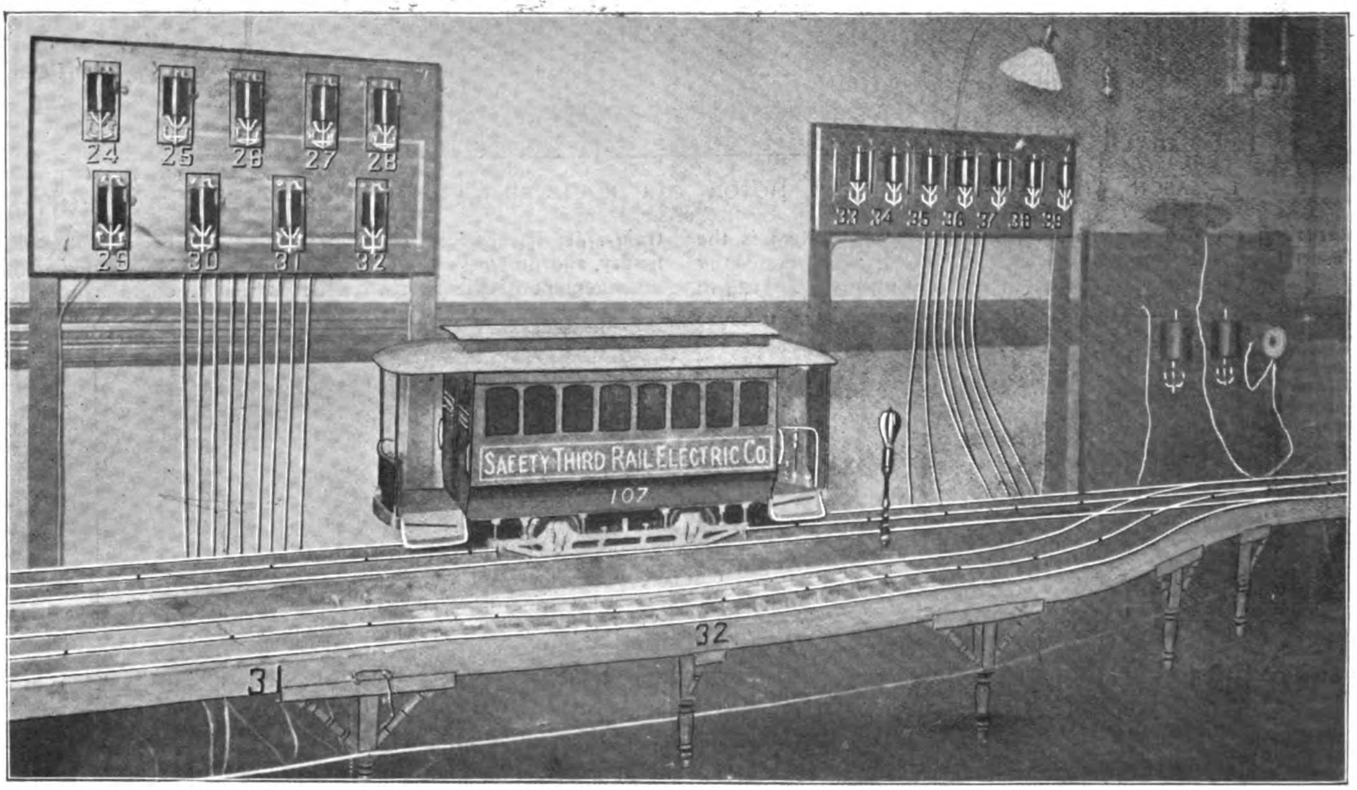

FIG. 1.—VIEW OF CAR ON MURPHY TRACK WITH VAULT SWITCHES.

will probably continue to do so for an indefinite period. To devise some means of avoiding the flimsiness and unsightliness of overhead construction and, on the other hand, the costliness of the underground construction, has been the aim of many an inventor, and it must be evident that if a golden mean between the two can be devised it must of necessity appeal strongly to street railway companies.

We propose in the following to describe the most recent attempt to solve this problem, due to the efforts of Capt. J. McL. Murphy, electrical engineer of the Safety Third-Rail Electric Company. To demonstrate the practicability of the Murphy system, the company has had constructed a miniature car and track, every detail of which is a perfect reduction to a scale 1-6 of the actual working size. This miniature railway system, installed in the Temple Court Building, New York, was last week shown in operation before a number of gentlemen prominently interested in railway matters, and we believe our readers will be interested in a description of the Murphy system, which embodies a number of novel features of operation.

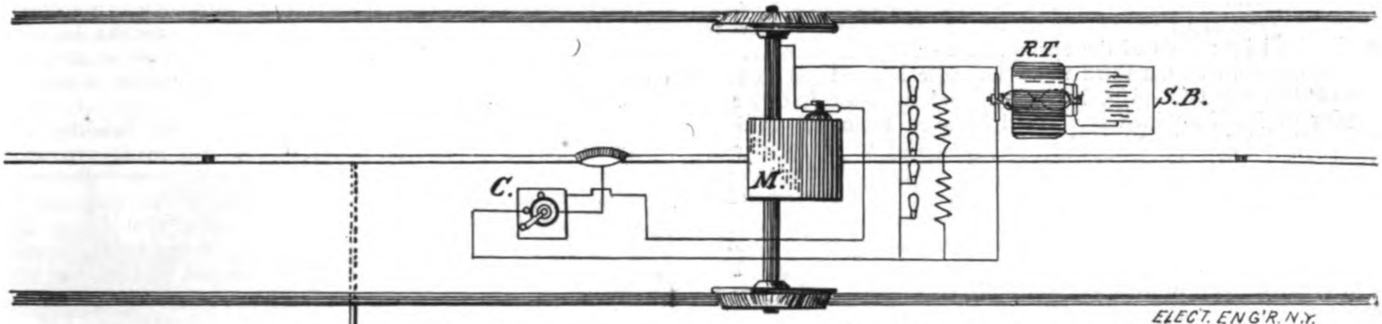
The accompanying illustration, Fig. 1, shows a part of the miniature track, which embraces all conditions met with in

actual practice, such as turnouts, track switches, signal lanterns, etc., and including a submerged section, so as to illustrate the operation of the car with the track submerged in water.

The system is based upon the employment of a central third rail divided into sections which carry the current to the motor, the outer rails being employed for the return current. The third rail, as stated, is divided into sections, the alternate sections being charged and the remainder dead. These two types of sections are separated by a short length of insulation consisting of a special composition. The feed wires are led in a duct between the tracks, in the double track system, and consist of lead-covered cable. These cables lead to switch vaults placed between the tracks and situated at intervals of a block. From the switches the rail feeders are led to sections of the track to be charged.

In order to understand more clearly the operation of the car the reader is referred to Fig. 2, which shows diagrammatically the equipment of the car together with one of the "vault switches." The car, it will be noted, is provided with a storage battery, S B, of ten cells, which furnish current for a rotary transformer, R T, which converts the 20 volts of the battery into 500 volts, the potential of the line current. As the car passes over the section to be charged, the local current generated on the car by the transformer energizes the vault switches, V S, shown in perspective in Fig. 1, one of which is connected to each live rail section. Passing over for the time being the operation of this vault switch, the closing of the latter sends the line potential of 500 volts into a charged section through the motor M on the car, and at the same time into the rotary transformer. The latter is thus reversed and becomes a feeder at the 20-volt end, the current generated being fed into the storage battery, and thus keeping it constantly charged.

The engraving, Fig. 2, together with Figs. 3 and 4, shows the operation of the vault switches, one switch being provided for each charged section of the third rail. As will be seen, the switch is provided with two windings, an inner and an outer. The outer winding is connected to the main line feeders, y', through the medium of the switch contacts or jaws, a. The inner winding is connected to the car storage battery and rotary transformer circuit, and raises the lower jaw of the switch, A, to the yielding contacts, D E. As soon as this contact is made, the heavier outer winding, s', connected to the feeder, y', is thrown into circuit, increases the power of the solenoid and still further pulls up the core and switch to a solid contact. The further motion of the core through the medium of an upper extension rod, P, automatically breaks the circuit of the inner winding at the switch, G, which winding then remains dead until the car leaves the section. When the car passes on to the next section, the solenoid becomes de-energized, the switch jaw, a, drop with the solenoid core and remakes the contact, G, closing the circuit of the inner winding, and thus leaving the vault switch ready to be acted upon at the passage of the next car.



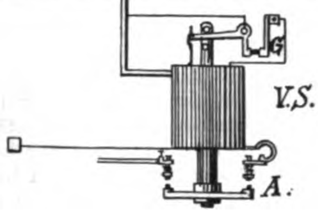


FIG. 2.—DIAGRAM OF CAR, TRACK AND VAULT SWITCH

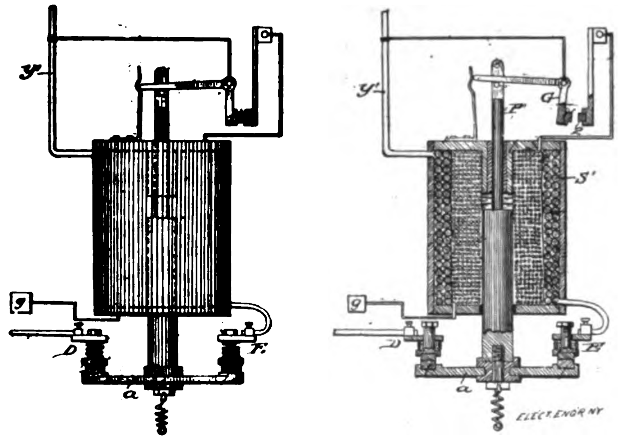
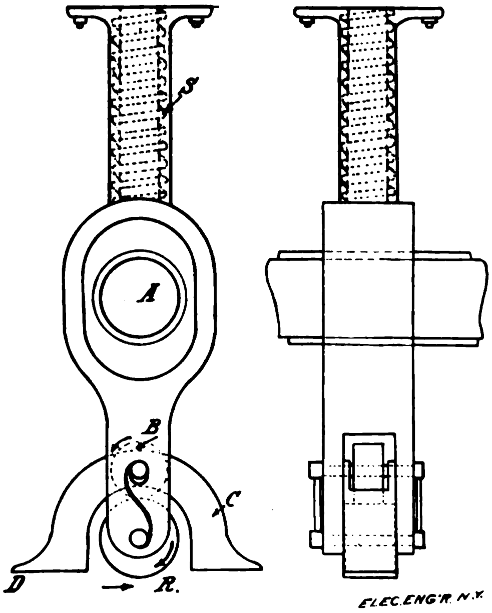
A good idea of the operation of the switch can be obtained by referring to Fig. 2. In this illustration the vault switch, V S, is shown as it appears when there is no car over the section and the main switch contacts, A, are open, with the inner solenoid contact, G, however, closed. Fig. 3 shows the condition of the switch at the first instant of contact of the shoe with the third rail. The main switch jaw, a, has been drawn up into contact and admitted current to the car motor. At the next instant, however, the heavy current which has been allowed to pass draws up the main contacts, a, to their full length, opening the switch, G, and hence the circuit of the inner winding, as shown in Fig. 4.



FIGS. 3 AND 4.—SHOWING VAULT SWITCH, TWO POSITIONS.



FIGS. 5 AND 6.—TROLLEY SHOE, SIDE AND FRONT VIEWS.

The trolley shoe employed with the Murphy system presents a number of novel features. As shown in the illustration, Figs. 5 and 6, it is suspended from the bottom of the car body, and its middle section is enlarged so as to encircle the car axle, A. At its lower extremity it carries a roller, R, which runs in contact with the third rail. Resting on top of this roller is a second roller, B, to which is attached the actual contact shoe,

C. As the car travels along, the revolution of the lower wheel, R, turns the upper wheel, B, in the opposite direction and tips one end of the contact shoe, C, over until it comes in contact with the third rail, the contact of the shoe with the rail being always at the rear end. Thus if, as shown in Fig. 5, the car be traveling in the direction indicated by the arrow, the end D would be in contact with the third rail, the other end being tipped up clear of that rail. The two wheels, B and R, are maintained in contact by the spring shown and the double contact is maintained by means of the spring, S, which presses the roller and shoe down to the third rail. The axle is insulated so that no contact can take place between it and the shoe frame, and a play of ⅜ of an inch is allowed between them in addition. The axle of the wheel, B, also runs in a slot so as to give it free play. To provide for the smooth running of the motor, the bearing surrounding the car axle by which it is suspended has been provided with ball bearings, as shown in Fig. 7.

The live sections of the third rail are eight feet in length, while the dead or insulated sections are six feet long. The trolley shoes, two in number, being placed 6 feet 6 inches apart, must of necessity always straddle the dead or insulated sections, and thus operate the switch of the section ahead, so that it is charged ready for the approach of the car. As soon as the shoe leaves the section behind, that section immediately becomes dead, as was shown above, when describing the vault switch.

The controller of the car shown at C, Fig. 2, controls both

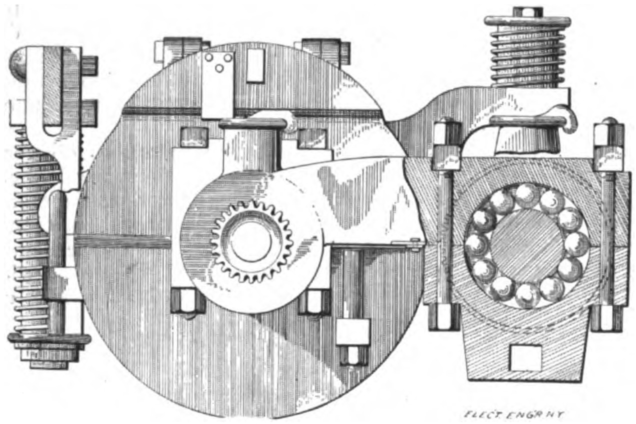


FIG. 7.—MOTOR WITH BALL-BEARING SUSPENSION.

the local car current and the main line current. Thus it will be seen that no rails can be charged or remain charged after the car has left the section. It will also be noted that under no circumstances can any person or animal receive a shock from the rail, for the reason that the full length of the car being twenty-two feet, the car body necessarily covers both charged sections, the two extreme points of which are covered by the car body, thus leaving no charged rail exposed, either ahead or behind. As a matter of fact, while the car is standing still there is no current in the track whatever, so that there is a double safeguard against anyone coming in personal contact with the charged conductors.

In addition to the operation of the car itself, the Murphy third rail system provides adequately for the automatic operation of the track switches and signals. The track switches, in fact, are operated by the controller on the front platform, which at the same time operates the visual signals indicating to the motorman that the switch is "O. K.," and signaling the motorman coming in the opposite direction. The system also acts as a danger signal at railroad crossings. In addition to this, and at the same time a switch is automatically operated in the vault connected to the track in advance, which cuts off all current from the car approaching in the opposite direction, thus avoiding collisions, while at the same time displaying a signal. This feature is especially adapted for single track roads. When the car, after clearing the switch, passes to a new section it automatically restores the vault switch to its original condition and leaves the line clear to be operated on by the next car.

As was stated above, when the car is at a standstill there is no current in the track, and hence under ordinary conditions no current would be furnished to the car for lighting or heating purposes when the car stops to take on or let off passengers. This condition has, however, been very ingeniously provided for by calling upon the storage battery for this work. As described above, when the car is running, the rotary transformer is constantly in operation charging the storage battery, and when the car stands still the storage battery provides all the current necessary for these two purposes, being constantly fully charged.

In cases where street car lines run out into suburban sections arrangements can be easily effected for automatically lighting up the road ahead for any desired distance, so as to give the motorman full view of the track and to warn people of the approach of the car.

In addition to the other precautions for the liability and safety of the system, Capt. Murphy has also made provision for the liability of the vault switches holding up or "sticking," by whatever means this may be produced. To provide against this contingency a fuse has been introduced so that if a switch should fail to open one, or two, seconds, or any longer period of time desired after the car leaves the charged section, the fuse will blow and cut that section out.

In the miniature railroad, shown in the engraving, Fig. 1, there is, as stated above, a section four feet long which is depressed and runs in a trough in which the rails are submerged half an inch below the surface of the water, which is two inches deep. In the experimental run of this miniature railway the water was fully saturated with salt and other material met with in street railway practice. The car was brought to a standstill over the submerged section and started from a dead rest. The leakage of current at 110 volts was only eight amperes. This, however, was insufficient to hold up the vault switch, and hence the car received no current, twelve amperes being the maximum required to operate the switch.

In the Murphy third rail system no departure has been made from the present standard practice for the equipment of electric street cars beyond one change in the controller and the installation on the car of the storage battery and transformer, which increases the weight only 600 pounds.

It will thus be seen from the description of the Murphy third rail system that it has been worked out with considerable care and that it has been especially designed to meet all conditions of actual working. If the operation in practice can be brought to the same perfection as that reached on the miniature system, the Murphy third rail system certainly has a very bright future before it.

Storage Battery Cars on the Grand Street Line, New York City.

SOME weeks ago the president of the Grand street crosstown line was authorized by the Board of Directors to employ an expert engineer to make an examination of the storage battery line now operating in Chicago. This examination was made, with the result that such a favorable report was presented that the directors further authorized the equipment of a small electrical plant at their car barn, and the operation of at least two storage battery cars, for a sufficient length of time to determine whether or not the conditions under which the cars would be required to operate in this city, would cause an increase in the cost of operation and maintenance over that obtained on the Chicago road.

Four cars were leased from the Chicago Electric Traction Co. (formerly the Englewood & Chicago Electric Street Railway Company), together with the batteries and other equipment necessary for the operation. An elevator and a 90 h. p. direct connected Westinghouse gas engine unit were installed at the Grand street car barns, and for over thirty days past, two of the cars have been in regular operation, making from 90 to 95 miles per day each. On account of the worn-out condition of the track, the operation of the cars has been carried on with considerable trouble. Weak joints and curves permitted the cars to jump the track, and caused a much greater expenditure of energy than would have been the case had the road been in good condition.

Another factor which would militate against economical operation is that the motors are designed for a normal speed of 16 miles per hour, whereas the speed at which they are now operating on Grand street is only six miles per hour. These motors are designed principally for long high-speed runs, such as occur in suburban operation, and therefore are at a disadvan-

tage when run at slow speed, combined with continual stopping.

Even under these unfavorable conditions, the power consumed has been very satisfactory, as the average energy recorded at the switchboard is 1.94 kilowatt hours per car mile, during the period from March 14th to 26th inclusive. It is only reasonable to assume that under favorable conditions of track and motor, the actual operation could be reduced to not over 80 per cent. of the above figure, or 1.55 kilowatt hours per car mile. This would give on the car an expenditure of considerably less than an electrical horse power hour per car mile.

Under the circumstances, all concerned feel very well satisfied with the operation of the cars. As the cars have demonstrated all that was necessary, they will shortly be withdrawn.

Municipal Electric Lighting.[1]—VII.

BY PROF. JOHN R. COMMONS.

MUNICIPAL DEPRECIATION FUNDS UNNECESSARY.

WE can now make plain another reason why a city need not accumulate a depreciation fund and why a private company must do so. In a city the entire taxable property of the citizens is liable to assessment when the time arrives for purchasing new machinery in place of old, while in a private company only the capital actually invested is so liable. In the former case, therefore, the increased tax rate for replacements would be so insignificant as to need almost no consideration; in the latter it would wipe out the dividends and reduce the capital stock to a mere speculative interest. For example, the assessed valuation of taxable property in Detroit is $209,586,330. The tax rate for all purposes is fifteen and seven-tenths mills on the dollar. The entire lighting plant cost $729,222. The electrical part of the plant cost $63,701. Supposing this part were to be entirely replaced in a single year, the tax necessary for the purpose would be only three-tenths of one mill, which would increase the tax rate from fifteen and seven-tenths mills to sixteen mills. If the same assessment were levied on a private company which had invested $730,000 in the enterprise the rate would be eight and seven-tenths per cent. (eighty-seven mills on the dollar). But the entire electric plant would not need reconstruction in a single year. Its replacement, together with that of the entire depreciable part of the plant, could be distributed over say twenty years. This depreciable part of the Detroit plant is $431,186, making $21,559 to be replaced each year. On the entire taxable property of the city this would be a rate of only twenty-six one-hundredths of a mill, bringing the total rate to 15.96 mills. On the private capital invested this would be a tax of three per cent. or thirty mills on the dollar. But this is not all. The private plant would, of course, be bonded for one-half its value, and the interest on the bonded debt at six per cent. would be a prior lien on the earnings. Consequently, the cost of replacement would come out of the stockholders representing but one-half the investment. The assessment on stock for replacing one-twentieth of the depreciable plant would, therefore, be six per cent. as against the twenty-six one-thousandths of one per cent. which the taxpayers would be assessed. The capital stock in the one case would be wiped out, but in the other the taxpayers would be unaffected. Even this comparison is unfair to the city of Detroit, for it must be remembered that in 1893 and 1894 the tax on property for lighting by a private company was $175,000 yearly for 1,279 lamps, while now it is only $144,000 yearly for all operating expenses and interest on 1,700 arc equivalents. This leaves a balance of at least $30,000 yearly, minus sinking fund and new construction without considering the increased lighting, on which to draw for replacements when needed, before the expense can be said to approach that of private lighting. Under such circumstances I do not see how the municipal authorities can be charged with "bad bookkeeping." Judged by private standards they could be so charged, and those thousands of private companies which are now distributing what ought to be their reserve funds in dividends to stockholders are either presuming upon their power to force the public to pay for replacements when they come, or their shrewdness in bolstering their stock and entrapping future innocent stockholders who in turn must reckon with the municipalities.

Below is a table showing the facts just stated concerning Detroit, together with comparative tables for smaller places. It will be seen that small places with heavier investments relative to taxable property than Detroit must incur a heavier tax rate for replacements. This rate is five-tenths of one mill in Braintree and seven-tenths of one mill in Reading, Mass., two and three times the estimated rate in Detroit. But the Braintree and Reading plants are both commercial and street plants, and this brings in a new consideration, namely, the relations between taxpayers and consumers in the maintenance of the electrical works.

TABLE IX.

COMPARATIVE BURDEN OF REPLACEMENTS ON MUNICIPAL AND PRIVATE CORPORATIONS.

	Detroit. Street Plant. 1897.	Braintree. Street and Commercial. 1894.	Reading. Street and Commercial. 1896.	Braintree. Street Plant. 1894.
Total valuation of taxable property	209,586,330.00	$4,424,225.00	$3,206,466.00	$4,424,225.00
Tax rate on $1.00	.0157	.0172	.0155	.0172
Total investment	729,222.00	54,600.00	67,098.00	30,160.00
Total cost electric plant	63,701.00	7,640.00	7,026.00	2,740.00
Tax rate on $1.00 necessary to replace electric plant entire	.0003	.00172	.0022	.0006
Assessment on capital invested necessary to replace electric plant	.087	.14	.103	.091
Total cost of depreciable plant—machinery, posts, lamps, lines	431,186.00	45,820.00	43,991.00	21,380.00
Tax rate on $1.00 necessary to replace 1-20th of depreciable plant	.00026	.00050	.0007	.00024
Same added to existing rate	.01596	.01770	.0162	.01804
Assessment on capital of private company (stock and bonds) invested, necessary to replace 1-20th of depreciable plant	.03	.042	.032	.035
Assessment on capital stock alone (estimated at ½ total capitalization	.06	.084	.064	.07

COST UNDER PUBLIC AND PRIVATE OWNERSHIP.

Heretofore I have considered only those cities in which the municipal plant is limited to street lighting. In such cities the taxpayers alone are concerned as to the charges for depreciation. But the inevitable tendency of municipal ownership is to enter the commercial field. Every one of the municipalities owning plants in Massachusetts has already added or voted to add this branch to its municipal plant. The advantages to the citizens in taking this step are so patent and unquestionable that when a municipal plant has once been installed they become restless under private commercial lighting. The city of Jamestown, N. Y., added its commercial plant after the street plant had been operating a couple of years, and one large consumer who had been paying $1,400 a year for lighting now gets his light from the city for $900. A prominent social club had been paying $450 yearly for lighting its rooms. In order to retain its custom the private company has reduced the charge for the same light to $120 a year. Lansing, Michigan, bought out the private plant and reduced rates at once from twenty cents per kilowatt to eighteen cents and again to twelve cents in two years.

[1]Municipal Affairs, Dec., 1897. A Reply to R. R. Bowker. See Elec. Engr.

MR. E. M. TAYLOR, of the Newark, N. J., Telephone Company, recently carried out some interesting work in telephone transmission between Newark, Jersey City, Harrison, Bound Brook, Union Hill, Plainfield and other places. The phonograph was used for both the reception and transmission of the songs, together with large megaphones, placed in the hall at Newark. The entertainment was under the auspices of the Seth Boyden Council, O. U. A. M.

STERLING ARC LAMP COMPANY, of the Borough of Manhattan has been formed with a capital stock of $100,000. The directors are Andrew Faulds, Jr., J. G. Galland, Paul Raff and Michael Wallstein.

The Growth of Telephony.

FEW things in the electrical field are more striking than the growth of telephony. The art which has grown up around the inventions of Bell, Gray, Edison, Hughes, Scribner, and others, may not be so obtrusive in its outward manifestations as electric lighting or the trolley; but its effects on the social economy are certainly as widespread and beneficial. The will of the Lord is heard in its still, small voice as clearly as in the roar of the big dynamos and the rumble of the electric cars, and it serves quite as efficiently as they, though less ostentatiously to maintain and increase that intercourse upon which civilization most vitally depends. Twenty years ago the telephone was unknown to mankind at large; to-day there are said to be just about 1,500,000 telephone subscribers in the world, of whom by far the larger half are in the United States. Recent figures, whose full authenticity we do not undertake to guarantee, say that the grand total is made up about as follows: The United States leads the list with 900,000 (?), then comes Germany with 140,000, and Great Britain with 75,000; Switzerland, 50,000; France, 35,000; Austria, 20,000; Russia, 18,000; Sweden and Norway, 16,000; Bavaria, 15,000; Denmark, 15,000; Italy, 14,000; Holland, 12,000; Spain, 12,000; Belgium, 11,000; Hungary, 10,000; Würtemburg, 7,000; Finland, 6,000; Japan, 3,500; Cuba, 2,500; Luxembourg, 2,000; Portugal, 2,000; Australia, 2,000. The remainder is divided among the smaller countries, from Roumania with 400, down to Senegambia with 100. Our own estimate is that there are not more than say, 600,000 telephone subscribers in this country. The Bell system has about 400,000.

The annual report of the American Bell Telephone Co., digested elsewhere in this issue, bears eloquent testimony to the growing use of the telephone. It is, moreover, to be borne in mind that this report no longer represents the full use in this country, for the reason that there are now hundreds of independent exchanges, some very large, and many of them very busy. Still, the Bell figures are impressive enough, with 919,121 instruments under rental; 1,962 exchanges and branch offices; and a total revenue by all the allied companies of $4,435,515. Most remarkable of all is the use made of the system, showing a total of 998,000,000 telephone connections per year, or 3,099,472 per day, or 8 1-10 per subscriber daily, at a cost of from 1 to 9 cents each connection, according to the service rendered. As each telephone talk is never less than a few hundred words, and as a telegram costs at least 15 cents, it will be seen that as a means of intercommunication the telephone has seriously distanced the telegraph. Taking into account the work of the independent exchanges, the guess may be hazarded that the total telephone calls in this country are now from 1,200,000,000 to 1,500,000,000 per year. It is open to question whether the number of telegrams sent by the public has yet reached 100,000,000 per year. Once more the doubt must be expressed, whether the telegraph is used in anything like the measure of its possible utility and cheapness.

Moreover, while the telephone for long distance work does not compare with the telegraph in cheapness, it is rapidly widening its range, in spite of the necessarily high price for the service, its instantaneity being the great recommendation. We understand that just recently in these anxious times, the use between New York and Washington for all manner of service, has been tremendous; while long lines of railroad are employing it more and more. We illustrate this week an excellent example of railway telephony. There will be more illustrations of this kind as the years go by. Looking at the whole situation squarely, we must confess our belief that the telephone art to-day in America is advancing very rapidly, as the result of the independent movement, which has justified itself not alone by its swift extension but by the stimulus applied by it to the old companies. There are Bell exchanges to-day, however, that have ever been progressive, and that by their lavish expenditure and employment of the highest talent have placed telephony in this country far above any sort of comparison with that in Europe. That they will continue to hold their own by steady improvement and by a continuance of judicious innovations in service, as well as by scientific methods of metering that service according to the price paid, is a probability few will dispute.

The Accuracy of Electric Meters.

OF all the commercial apparatus, upon which popular abuse and denunciation have been heaped, none has needed less defence or had to stand severer attacks than the meters for registering the consumption of current. The mistrust of the general public as to the honesty of large corporations and the belief that they are paying for more than they have actually received may be ascribed to a natural human instinct, or, perhaps, a force of habit contracted while dealing with companies distributing gas, water or steam. Be this as it may, the condemnation of the electric meter, justifiable as it may have been in the past, has had its birth in nearly every large city in the United States, and according to latest reports has at last reached San Francisco, way off on the Pacific coast. We hope that this popular misconception or prejudice will continue its course in a westerly direction, until it is in the deep bosom of the ocean buried.

While it is, of course, impossible to guarantee the absolute accuracy of any commercial piece of apparatus, or to insure its correctness after it has been removed from the care and supervision of the officials of a company, it may be stated at the outset that no company can win permanent success by indulging in dishonest practices. To perfect their machinery, substitute the new and improved for the old and obsolete, to give better service and not overcharge customers is the underlying basis of all successful business management. We can cite no better illustration of this than the results achieved in the experience of the Edison Electric Illuminating Company, of New York. In its annual report for the year 1897 the following significant reference is made to the question of meters: "The Meter Bureau, under the general charge of the Controller, has continued its excellent efficiency during the year; it had under its care on December 31, 1897, 9,941 meters, of which 6,744 were Edison chemical meters and 3,197 mechanical meters. The usual careful attention has been given to complaints from customers, as to amount of bills, etc., of which 1,530 were received during the year. In connection with these complaints there were found 215 errors, of which 138 were clerical and 77 technical. The proportion of errors to bills rendered was 1 in 511, or less than one-fifth of 1 per cent., an increase of proportion above that of 1896, due in large measure to the extensive change from chemical to mechanical meters, involving a considerable strain on the Meter Bureau. There is reason to hope that the proportion will be considerably reduced in another year. The company continues its policy of offering to submit any disputed case to arbiters, and in general has succeeded in showing to customers its desire to treat every one with entire fairness."

In calibrating the mechanical meter care is taken that it does not run more than 2 per cent. fast or 5 per cent. slow, the meters all running a trifle slow on light loads. Applying figures to this apparently startling revelation, one finds that the customer will be but little affected even if the meter is out the maximum amount. For light loads the error might amount to a few cents each month, and for heavy consumers the companies have arranged such special rates and discounts as to cover any possible slight error in the meter, which, as stated, never exceeds 2 per cent. Again, should the company find that the meter was out more than 2 per cent. a reduction of the amount in excess of this percentage is made on the customer's bill. Meters are inspected at regular intervals or are checked at the consumer's request. And now we ask the consumer, whether there is any commodity, any piece of apparatus which he purchases, which is subject to closer checks and more accurate determinations than is his electric meter. We believe not, and are certain that the mechanical meter, if not tampered with, has no inherent faults and has fulfilled the following conditions essential to a successful meter: 1, accuracy; 2, range; 3, economy of energy; 4, simplicity; 5, durability; 6, minimum attention; 7, ease of reading; 8, ease of verification; 9, precautions against tampering; 10, cheapness; 11, not liable to freeze; 12, works equally well with direct and alternating currents; 13, independent of frequency; 14, good contacts; 15, portability.

The mechanical meter with plainly visible dials and in a glass case will undoubtedly remove the existing prejudice, for faith in any form of meter cannot be established, unless the people see the wheels go round.

Dr. Slaby On Wireless Telegraphy.

IN view of the general deep interest in electrical circles, touching the subject of wireless telegraphy, we venture to direct the attention of our readers to the discussion of the subject by Dr. A. Slaby, of Charlottenburg, Germany. In an article in the Century Magazine, entitled "The New Telegraphy," Dr. Slaby gives a splendid résumé of the work done by the early experimenters, such as Hertz and Tesla. He credits the former with establishing experimentally the identity of electricity and light, in quantity even if not in quality, and the latter with having made the first practical deductions, by directly transforming the electrical rays into rays of light. He calls the resonator of Hertz a weak and shortsighted electrical eye which was first made in the form of tubes, such as Branly suggested, by Lodge, whom he terms the father of the idea of telegraphing with electric rays and such tubes and who was the originator of the word "coherer." But, continues Dr. Slaby, the electrical eye which Marconi uses is essentially more sensitive; we may call it a clever improvement on the resonator of Hertz. He discusses in detail the coherer of Lodge and the receiver and transmitter of Marconi, establishing once for all the latter's indisputable claim of having worked out a practical arrangement for the apparatus which by the use of the simplest means produces a sure technical result. Marconi made telegraphy by sparks possible by using, on the one hand, earth connection between the apparatus, and on the other, the use of long extended upright wires. By this simple but extraordinarily effective method he raised the power of radiation in the electric forces a hundredfold. Dr. Slaby then describes the early experiments made in the Bristol Channel under the able supervision of Mr. Preece, the engineer-in-chief of the British Telegraphs, and his own later experiments at Potsdam, which were made possible by the liberality of the German Emperor. At a distance of eighteen kilometers, signals could be easily deciphered. Dr. Slaby concludes his very interesting articles by holding that we are really in the opening chapters of a grand development and none can say how far, and whither the path will lead us. He mentions the importance of the discovery in the military field, and for lighthouses and lightships, since the system works as surely on a bright day as by night and in fog. The chief condition for the success of spark telegraphy is that all obstacles which are found in front of the transmitter wire must be cleared away. An undeniable weakness of spark telegraphy, however, is this: every telegram is imparted to the whole world, every receiver can take it up. For practical purposes, if one desires to protect one's self from having despatches read by others, there remains always the use of a code arranged beforehand. In war, to be sure, telegraphy would become impossible as soon as a hostile spark generator should cause a permanent disturbance of the characters. A very interesting battle might occur in the waves of the ether. Notwithstanding these undeniable shortcomings, there is reason to rejoice at the discovery of the new telegraphy, and we cannot allow this reference to the subject to pass without noting also the very efficient work done in this country by Mr. W. J. Clarke. After months of patient experimenting, this inventor has designed and made available for use excellent apparatus suitable for the requirements of wireless or spark telegraphy in America, as shown in his lecture last week before the New York Electrical Society.

Electricity In Warfare.

WE are sorry to note that at this writing it begins to look like inevitable war with Spain, first of all to purge the national conscience of further complicity in the atrocities in Cuba; and, secondly, to avenge the "Maine," for no one can read the official report through without recognizing the culpable carelessness, or worse, of the foreign authorities to whom, as friends, the safety of the ship in their harbor was committed. Be the causes and reasons for war what they may, there is plenty of evidence that electricity as never before will play its part. We publish several items this week as to the electrical preparations going on, and each day brings some new tidings of electrical preparations, ashore and afloat. If the actual test of grim war comes, there will be deep interest in observing how valuable some of these preparations are. Some of them, such as the linking together by telegraph and telephone of coast defenses, and equipping even land forces with searchlights, are obvious and primary. But as Lieut. Fiske showed elaborately in our pages about a year ago, there are many novel applications, and it is these that most army and navy experts are concerned about.

We are heartily glad to note the steps taken to enroll volunteer electrical aid, and to know that such men as Capt. Eugene Griffin, Mr. Frank J. Sprague, Mr. H. Le Roy Emmet, and others, have been giving it their best thought and earnest effort. Whether war comes or not, one result of these stirring times must be the organization as a permanency of a strong reserve or volunteer electrical corps for duty along all our coast line.

Trolley and 'Rickshaw.

A TERRIBLE fellow that trolley, from the way in which he cuts into the established methods of travel wherever he goes. And like all his predecessors, he is cause of lamentation. If one delves into literature of the period when coaches first came in, there are storms of protest against giving up horseback transportation and sitting boxed up in a vehicle. Then as the steam locomotive came to the front, the stage coach became the theme of conservative lament, and around it was weaved all the charm of legend and romance. Now the steam locomotive is getting into the stage of pathos and swan song, while from the far East there reaches us a faint poetic appeal against modernity, as represented by the trolley. Our old friend, Mr. Thomas Ahearn, of Ottawa, Canada, now on his third or fourth voyage around the world with his family, sends us from Kandy, Ceylon, a weird outburst of grief, in verse, over the passing of the 'rickshaw. The sentiment is summed up in this terse stanza: "What more pleasant than the motion, Of a 'rickshaw speeding far? What more hateful than the motion, Of a Western tramway car?" But the 'rickshaw, and its coolie, and the khaki suit and belt of red must go. The unshod feet of the turbaned biped steed must go, before the invasion of the clanging, whizzing trolley. The loss is all on the side of the picturesque in the daytime, but at night the brilliant, flashing car will redress the scale; while fifty years hence our descendants will, like the Cingalese poet, drop into verse over the departing glories of the last trolley, and all its long era of marvel and mystery.

MISCELLANEOUS

Considerations Governing the Design of the Crocker-Wheeler Slow Speed Motors.—II.

BY GANO S. DUNN, CHIEF ENGINEER.

THE armatures of these motors have been difficult to design, since the low speeds require an extremely great number of convolutions, and the requirements of high efficiency compel the use of a wire of comparatively large area. This makes the proportion of copper to iron in the armature so great that it is difficult to find room for it, especially where the core is kept as small as possible to favor high efficiency at partial loads. An armature core, partially wound, is shown in Fig. 5. Were it not for the peculiar shape of the teeth employed, the wide slots between them would render the machine so inefficient as to be of little value. The overhanging lip distributes the dense magnetic flux coming up through the narrow tooth, so that by the time it reaches the polar surfaces of the field magnets the density is nearly uniform and eddy currents are avoided. The lip of the tooth serves also as a lock to hold the winding in place against the action of centrifugal force.

For the smallest size the wire is wound in place in trapezoidal slots. The core is made in halves to permit this to be done in a winding lathe and the parts are subsequently joined and mounted on the armature spider. For all the other sizes the winding is done on forms, previous to application to the armature. Each coil is wound, then properly shaped so it will nest with its neighbors, and then carefully insulated with layers of oiled muslin and tape applied by hand. When the winding has been put on the core, it is held down by the clamps at each end, and the connections of the coils are made to the commutator. The commutator bars have tails sufficiently long to keep cool and hold the solder, even if the commutator should through accident, become overheated.

The winding may be connected for multiple circuits or for two circuits, depending on speed, voltage and other conditions. Two-circuit windings are principally used because of the larger wire and fewer turns, making them simpler and cheaper, and because in these windings each pole has only a fractional influence on the total counter e. m. f., and therefore an eccentricity of the shaft with reference to the field bore or of the armature on the shaft or an inequality of some of the field windings, will not disturb seriously the electrical balance of the armature circuits. The two-circuit windings are always used for the low speeds, for several of the above reasons, and because at such speeds where the output is small, they permit the operation of the motor with as few as two sets of brushes if desired.

The windings of these motors, of which each individual coil is completely wrapped with insulation, are impervious to moisture and to dust, which permits them to be run in places where the air is filled with fine particles, without fear of damage and without the anxiety felt for an exposed winding, some parts of which are impossible to reach when cleaning. The manner in which they are applied to the core permits such ample ventilation that severe overloads can be withstood without destruction of the insulation, although they raise its temperature, of course, above the normal point.

The mechanical clearance between armature and field is for several reasons made large. It insures sparklessness, and, under the conditions of regulation, to be described later, is specially desirable. It insures, also, proper operation, even if, through wear of bearings or from failure to properly install, the armature is not exactly concentric with the field-bore. With an air gap of 1-16 inch, for example, a variation of 1-32 inch, from wear of bearings or other causes, would make a 50 per cent. change in the reluctance, and completely upset the magnetic balance of a multiple-circuit machine, but with an air gap of ¼ inch, a 1-32 inch variation would make only 12½ per cent. change in this reluctance, an amount within the power of the machine to withstand. Furthermore, in the first case, the unbalanced mechanical force tending to pull the armature sidewise, would be so excessive as to heat the bearings and cause serious loss of efficiency, if not a breakdown, while with the latter case the unbalanced force would be much smaller because of the small variation. A large air gap, too, permits the armature to get rid of its heat much more readily, and prevents the transference of heat to the field coils.

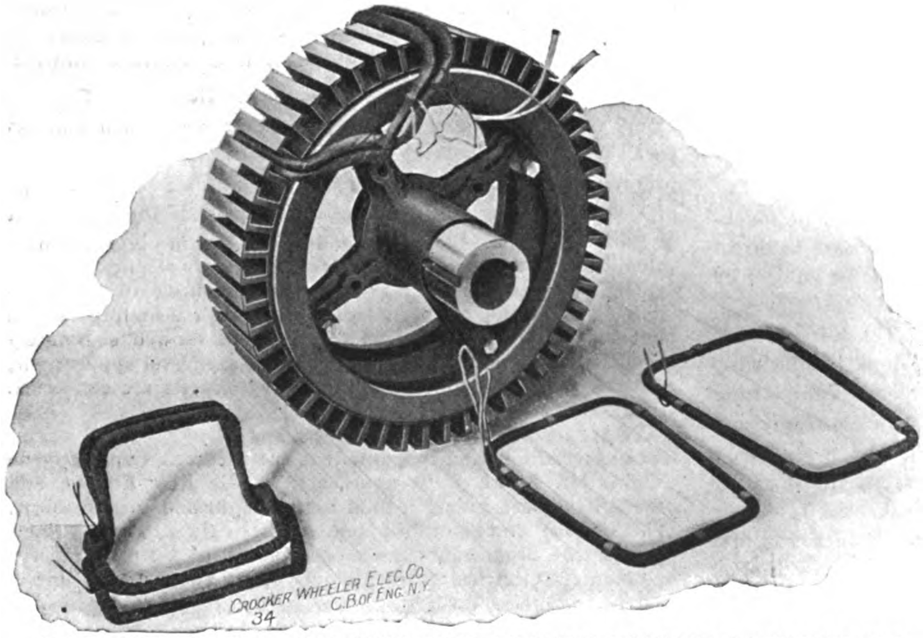

FIG. 5.—SIZE 1-100 C. W. ARMATURE CORE, SHOWING METHOD OF WINDING AND APPLYING FORMED COILS.

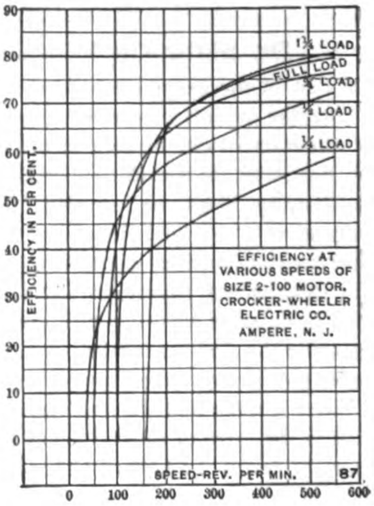

FIG. 6.—EFFIENCY AT VARIOUS SPEEDS OF SIZE 2-100 C. W. MOTOR.

The power of these machines is designated by the horse power each gives per 100 revolutions, and the sizes are therefore designated as follows: ½-100, that is, ½ h. p. per 100 r. p. m.; 1-100, 2-100, 3-100 and 5-100.

Fig. 6 shows the efficiency of windings of a 2-100 machine, covering a range of speeds from zero to 500 r. p. m., when loaded at ¼, ½, ¾, full, and 1¼ capacity. Where a curve indicates zero efficiency for a given speed, it means that the winding which would give that speed with the armature not loaded would have resistance enough to stall the armature if the load of the particular curve were demanded. Thus, from the curve, an armature which would run at 70 r. p. m. free would be stalled if called upon for three-quarters of its rated torque.

The upper limit of speed, on the other hand, is affected by no condition of armature resistance, but only by the centrifugal strains to which it is safe to subject the revolving parts, and by the capacity of the commutators to carry the large outputs the high speeds involve.

While special cases can be accommodated by alterations in de-

sign, the upper limit of speed for these machines is 500 r. p. m. for sizes ½-100 and 1-100, 400 r. p. m. for sizes 2-100 and 3-100, and 350 r. p. m. for size 5-100. It is possible to develop the same torque at all speeds without overheating because of proportions which make the temperature rise little dependent upon speed or actual h. p. output. For instance, if the armature is wound for a low speed, at which its ventilation is less, the hysteresis is also lowered, and this reduction serves as a compensation.

LETTERS TO THE EDITOR

The Proposed Electrical Corps.

I have seen a great deal lately about the proposed organization of a corps of electrical engineers for use in case of war, and similar to a corps said to have been formed in England some time ago. Now, how could such a corps be trained and for what particular purpose? Would those desiring to remain on land be given a special two weeks' course at Willett's Point and those taking up the navy have the same at Newport, or would they just trust to luck and a good brain training, and enter as privates same as any lineman or dynamo tender, and take the "haw bucking" of officers having a mere smattering of electrical training as compared with this corps? To make any valuable use whatever of the very considerable technical knowledge of such a corps, it seems to me it would have to be trained on the lines of the army and navy needs, and that much of the work would be special and almost personal. Please elucidate or develop some plan.

A. H. A.

Buffalo, N. Y., March 28, 1898.

Mr. Reid's Criticism and Its Critic.

I NOTE a letter in your issue of March 24 taking exception to various statements in my review of Wiener's "Dynamo Electric Machines." While I do not consider it a part of a reviewer's duty to uphold his opinions against anyone who may assail them, since everyone is at liberty to examine the book and form his own opinion, yet in this case, at your request, I will answer the objections advanced as fully as I can in the limited time at my disposal. My statements in regard to the misleading character of the title of the book, and to the effect of commutation on the armature flux, although they are mentioned in the article referred to, are not denied. Two other objections are prefaced by the expression "the writer believes," which he has a perfect right to do.

The densities referred to in table 6 and called "Field densities" appear to be pole face densities, although in the article referred to they are said to be gap densities. To whatever part of the magnetic circuit they belong, they are incorrect, since they should not increase as a regular function of the capacity, and are, in fact, affected by a multitude of conditions, such as speed, form of field magnets, gap length, requirements as to regulation, temperature and so on.

The statement of the law of E. M. F. at the bottom of page 47 differs radically from the statement of the same law given in the first sentence of article 4, page 6, in that the former includes length and cutting speed of conductor, which the latter does not. The statement on page 6 is correct.

In the case of series wound armatures with cross connected commutator bars, the author of the book simply misconceived the object of the cross connection. Each commutator segment is connected to one end of an armature coil, and each bar has exactly the same functions to perform; and therefore none of them is extra, but each in turn is concerned in commutation while under the brush.

The sensitiveness of iron to changes of magneto-motive force depends on its previous magnetic history, being more sensitive to increase of magneto-motive force on the ascending leg of the hysteresis curve and to decrease on the descending leg. If the author's statement were true, a small m. m. f. could be made to produce a very high density by being applied and removed a number of times, each application increasing the density more than the removal would decrease it.

In the first paragraph of page 34 increased diameter is said to allow of a decrease in the depth of the winding, which only applies to smooth core machines, to which the author does not limit the statement.

In regard to the review as a whole, it was written at your request, and after a careful study of the book. I have had no reason to change my opinion since that review was written.

THORBURN REID.

New York City, March 28, 1898.

W. J. Clarke's Lecture on Wireless Telegraphy.

IN his interesting lecture on Marconi's system of wireless telegraphy, delivered March 30, 1898, before the New York Electrical Society, Mr. W. J. Clarke stated that the electric waves caused no noticeable motion of the filings in the coherer, that is, none apparent to the eye even when aided by a powerful microscope (2,000 diam.). And this is not surprising. Why should they move?

The diminution in the ohmic resistance might be explained as follows: The ether waves induce an electric charge which breaks down the resistance of the dielectric between the particles in the coherer, and establishes minute arcs whose resistance is comparatively very low so that they are easily maintained by the battery in circuit. When the waves discontinue the jarring of the decoherer sets the air in the coherer in violent agitation, sufficient to blow out the arcs and thus raising the circuit to its initial high resistance.

To verify, or perhaps disprove the above theory, I would suggest that the coherer be examined in the dark and also a chemical examination of the contents of the coherer might be made after it had been in use for some time.

RICHARD KOCH.

April 1, 1898.

NEWS AND NOTES

Electrical Preparations for War.

THE Government is in correspondence with the General Electric Company relative to the cost and time of equipping every fortification along the Atlantic and Gulf Coasts with powerful searchlights, and it is believed that the contract will be let shortly. The contract will involve the expenditure of over a quarter of a million of dollars, as all the fortifications would have to be supplied with dynamos to furnish power for the lights. Should the occasion demand, the fortifications could all be equipped with lights in about four months.

The General Electric Company, which is constructing the electrical apparatus for the cruisers "Kentucky" and "Kearsarge," is pushing the work with all possible speed. These ships will be the first to be equipped with electrical moving turrets and hoisting machines. The General Electric people expect to complete the contract in about a month's time.

As a result of representations made by Capt. James Allen, signal officer stationed at Governor's Island, to Brigadier General A. W. Greely, Chief Signal Officer, of the absolute necessity of the expenditure of more than $25,000 in the telephonic and telegraphic connection between the fortifications in New York harbor, New York will get $25,000 more to complete thi work according to the original plans. Boston will get about $10,000, Philadelphia about $5,000, and Washington, Baltimore, Newport, and Portland, Me., will also get increased appropriations. The total increase for the Department of the East is $96,000. This increased appropriation will make it possible to do an especially important work. All coast fortifications are provided with range finders for the purpose of determining the distance from the fortification of an enemy's vessel. These, if they are to be used effectively, must be supplemented by telegraph apparatus, to enable the man in the tower to telegraph to the gun pits the range of the approaching vessel. The majority of the range finders in the fortifications are now so equipped. Now every one will be so within thirty days.

Both the War and Navy Departments have recently placed "rush" orders in Chicago for telephone supplies for coast forts

and navy yards. All orders have been marked "emergency purchases," indicating that the supplies were to be paid for out of the fund placed at the disposal of President McKinley by Congress. A full telephone equipment has been shipped to Pensacola, Fla. The points for which the telephone equipments are destined embrace all coast defense forts, and it is the intention of the Government to connect these with each other and all with Washington. The apparatus was supplied by the American Electric Telephone Co., of Chicago.

From one of Gen. Merritt's staff officers it has been learned that the Western Union and the Postal Telegraph companies have begun to organize corps of skilled electricians, whose services are to be offered to the Government should war be declared. The Postal Telegraph Company has already organized three companies of fifty men each in New York and an equal number in Boston for this service. The particular work expected of the men is the laying of submarine cables and connecting them with submarine mines and torpedoes. Every man in each company has been provided with a kit of tools, which, under orders, he carries with him day and night. The men have been informed, it is said, of the service expected of them, and they have been informed that, should war be declared, they would draw their salaries from the company as well as their pay from the Government.

The Safety Insulated Wire Co., of New York City, has been extremely busy on its rush order for cables for the Government, and has been working night and day to get the cables made and shipped. A lot more wire and cable has been called for, and contracts were to be awarded Monday, April 4. The specifications call for twisted pairs ærial wires, twisted pairs underground cables, lead covered, and a three conductor, lead-covered underground cable. Those who bid for the work must state the shortest possible time in which they can furnish five-mile lots of the wire and the cables. The bids must also state how soon after the delivery of the first lots 100 additional miles of ærial wire, in five-mile lots, can be delivered, and how soon sixty miles of the underground lead-covered cables and twenty miles of the three-conductor underground cable, each in five-mile lots, can be delivered. In awarding the contract, quickness in delivery will be considered quite as much as the price.

Most of the cable and wire will be used in connecting the range finders with the gun pits in the different forts. Some of it, however, will be used in connection with the work of mining the waters about a few of the fortifications.

Capt. Eugene Griffin, vice-president of the General Electric Co. and formerly of the U. S. Engineer Corps, has been in close consultation with the authorities in Washington. He has busied himself the last few days in organizing here an electrical corps from the ranks of the General Electric Co. and the New York Edison Co., as well as in organizing similar staffs at other Atlantic ports.

The Brooklyn Edison Co., secretary Royal C. Peabody, reports, is in readiness to aid the Government with searchlights and current for same, all along the Eastern shores of the Lower Bay, as far out as beyond Coney Island.

The East Pittsburg shops of the Westinghouse Electric and Manufacturing Co. are rushed with Government orders for electrical instruments and firing apparatus for submarine mines. Electrical automatic machines for the control of floating mines, torpedoes and signaling under water are included in the order. A new machine designed by Lieut. A. C. Engard, of the engineering corps of the navy, for the management of torpedoes, is being made, and it is said that it is unexcelled for accuracy, rapidity and destructiveness.

The Walker Co. at Cleveland has been busy on Government work, including orders for gun carriages.

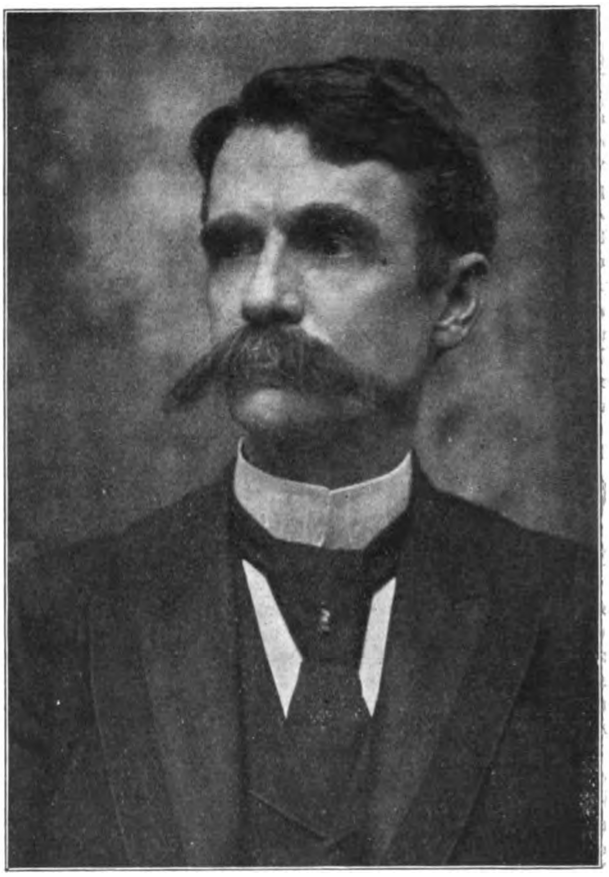
THE "MAINE" REPORT bears emphatic testimony to the fact that the electric light plant was all right in every respect. Lieut. G. M. F. Holman, who was in charge, testifies that the shock was precisely similar to many other submarine explosions he had heard. The electric wires were separated from the magazine by a double plating of glass, and there was nothing unusual about the temperature of the dynamo room.

A PROTEST. In three days, over 4,000 telephone subscribers in Massachusetts protested against the bill to put the telephone companies of the State under the control of the gas and electric light commission.

PERSONAL

Mr. W. D. Sargent.

THE fact that the New York and New Jersey Telephone Company is just marking another stage in its rapid growth by the occupancy of its fine new telephone exchange building, recently illustrated in these pages, directs interest to the personnel of the management, and especially to Mr. William Dunlap Sargent, vice-president and general manager. This gentleman is well known and highly esteemed in telephone circles. He was born in Pennsylvania, and entered the telegraph service of the Pennsylvania Railroad Company at the beginning of the war. He served for a brief period during the war in the United States military telegraph department of General Burnside at Cincinnati, and afterwards entered the service of the Western Union Telegraph Company, serving as operator, manager and assistant electrician. In 1873 he was superintendent of the original organization of the American District Telegraph in Philadelphia, and in 1877 became associated with Mr. Thomas E. Cornish, of Philadelphia, in the organization of the Bell Telephone Company, of Philadelphia. In 1882 he accepted a position with the New York and New Jersey Telephone Company, Brooklyn, since which time he has been uninterruptedly connected with the telephone service. Mr. Sargent's long and varied experience in the various branches of electrical service makes him, and he is considered as one of the leading telephone engineers of the country. He is a member, in Brooklyn, where he lives, of the Riding and Driving, Montauk and Brooklyn clubs. He is also a member of long standing in the American Institute of Electrical Engineers. We are indebted to "Brooklyn Life" for the excellent portrait herewith presented.



WILLIAM DUNLAP SARGENT.

PROF. S. H. SHORT has recently given a syndicate writer for a large number of papers a very interesting article on novel and possible uses of electrical methods in warfare.

REPORTS OF COMPANIES

Annual Report of the American Bell Telephone Co.

THE annual meeting of the American Bell Telephone Company was called to order in Tremont Temple, Boston, on March 29. President John E. Hudson read the report to stockholders, and the treasurer's statement. The election of officers resulted as follows: Clerk, Charles Eustis Hubbard; treasurer, William R. Driver; directors, Charles W. Amory, Thomas B. Bailey, Francis Blake, George L. Bradley, Alex. Cochrane, T. Jefferson Coolidge, Jr., J. Malcolm Forbes, Henry S. Howe, Charles Eustis Hubbard, John E. Hudson, Charles E. Perkins, Thomas Sanders, Moses Williams.

The annual report issued to the stockholders showed that the number of instruments in the hands of licensees, under rental, Dec. 20, 1896, was 772,627; Dec. 20, 1897, 919,121; increase, 146,-494.

The working statistics, Jan. 1, 1898, and the increase since Jan. 1, 1897, are as follows: Exchanges, 1,025; increase, 58; branch offices, 937; increase, 105; miles of wire on poles, 327,315; increase, 40,683; miles of wire on buildings, 13,776; increase, 1,182; miles of wire underground, 282,634; increase, 47,833; miles of wire submarine, 2,675; decrease, 143; total miles of wire, 626,400; increase, 89,555; total circuits, 295,904; increase, 31,259; total employés, 16,682; increase, 2,257; total stations, 384,230; increase 48,986.

The estimated number of exchange connections daily in the United States, made up from actual count in most of the exchanges, is 3,099,472, or a total per year of about 998,000,000.

The number of daily calls per station varies in different exchanges from 1 7-10 to 18, the average throughout the United States being 8 1-10, which is the same as the number reported last year.

The average cost to the subscriber by exchanges varies, according to the size of the exchange and character of the service, from less than 1 to 9 cents per connection.

Extra territorial and toll lines—Miles of pole lines, Jan. 1, 1898, 67,791; increase, 7,238; miles of wire, 324,88,; increase, 56,017.

The average daily number of toll connections is 75,208, or a total per year of about 24,200,000.

The total revenue reported by all companies for the year 1897 was $4,435,515.40, and the earnings of extra-territorial lines included in the above sum amounted to $1,949,132.61. Of the last amount this company received $211,507.21, an increase over 1896 of $29,241.89, not including earnings of the American Telephone & Telegraph Company.

The output of telephones and the increase of the number of exchange subscribers reported by the companies operating under our licenses are unprecedented in the history of the business. In fact, the gain of exchange stations recorded for the past two years equals the aggregate gain of the six years which preceded.

The system of measured service continues to grow in public approval. The subscriber pays for the specific number of outgoing exchange connections for which he contracts, or as many more as his needs require, and is at no expense for inward calls. This system of charges, based upon the amount of usage, is doubtless the more logical one, and its introduction has resulted in extending the service of the telephone to large numbers who would not otherwise have employed it as regular subscribers. While it supplements most usefully the older system of commutation, or unlimited service at yearly fixed rates, it is not likely to supersede it, for there will always remain a large proportion of the subscribers whose wants can be met only by the unrestricted use of their own circuits, with the right to call into requisition, as often as they desire, the circuits of other subscribers to the exchange, as well as the system of trunk lines which are necessary, in the great cities, to connect the numerous offices into which the exchange is divided. With the increase of the number of subscribers in an exchange, it is obvious that this right of unrestricted use becomes of larger consequence and of larger value. Much is to be said, therefore, in favor of the retention of both systems together, as contributing, in the largest degree, to the interests of those who regularly employ the telephone in the conduct of their affairs.

During the year the long distance company's lines have been extended to reach Omaha in the West, Minneapolis to the North, and southerly to Petersburg and Norfolk. There were in operation Jan. 1, 1898, 8,778 miles of pole line and cable, and 116,116 miles of wires connecting 238 offices; a gain during the year of 1,433 miles of pole line and cable, 8,706 miles of wire, and 55 offices.

The new construction completed in 1897 by companies with which we have contract relations, amounted to $8,712,914.10. Of this sum, $4,865,317.92 was expended upon exchange construction and equipment, and $3,847,596.18 upon toll lines. In addition to the above, $1,484,331.71 was invested in real estate to be used for company and exchange purposes. The entire expenditure for construction, including real estate, to the close of 1897, has been $85,946,102.27.

The Long Distance Company had invested, up to Dec. 31, 1897, in line construction, franchises, equipment, and supplies, $13,888,751.81. The company shows an increase in gross earnings in 1897 over 1896 of 16.1 per cent., the amount for 1897, gross, being $1,897,293.95.

The statement of Treasurer William R. Driver is as follows: The ledger balances, Dec. 31, 1897, were:

DEBTORS.

Telephones	$1,772,596.55
Real estate	1,052,695.92
Stocks and bonds	52,287,205.59
Merchandise and machinery	18,319.68
Bills and accounts receivable	3,275,059.70
Cash and deposits	1,833,964.11
Total	$60,779,841.55

CREDITORS.

Capital stock	$25,886,300.00
Capital stock premium account	6,110,582.00
Debenture bonds, 1888	2,000,000.00
Bills and accounts payable*	1,216,330.89
Patent account (profit and loss)	12,399,047.16
Profit and loss	6,551,431.94
Reserve	4,025,628.29
Surplus	2,590,521.27
Total	$60,779,841.55

*Of this amount $1,164,883.50 is for the dividends payable Jan. 15, 1898, to stockholders of record Dec. 31, 1897.

The comparative statement of earnings and expenses is as follows:

EARNINGS.

	1896.	1897.
Rental of instruments	$1,238,378.03	$1,597,959.36
Dividends	2,616,307.00	3,085,379.00
Commission from ex-terr. lines	182,265.32	211,507.21
Commission from tel. business	34,046.88	33,174.32
Real estate	80,864.38	84,709.85
Interest	171,355.23	117,071.93
Miscellaneous	4,107.41	1,043.25
	$4,327,324.25	$5,130,844.92

EXPENSES.

Expenses of operation	$409,052.31	$509,314.02
Legal expenses	100,744.78	136,333.49
Real estate	40,117.87	41,560.76
Interest and taxes	303,731.38	273,961.92
Miscellaneous	97.47	......
	$943,743.81	$961,170.19
Net earnings	$3,383,580.44	$4,169,674.73

Surp. acct., Dec. 31, 1896	$2,151,011.61	
Net earnings, 1897	4,169,674.73	
		$6,320,686.34

Surp. acct., Dec. 31, 1897		$2,590,521.27

Bell Telephone Output for March.

The American Bell Telephone Company's monthly statement of the output of instruments for the month ended March 20, with comparisons, is as follows:

	1898.	1897.	Changes.	
Gross output	28,909	19,192	Inc.	9,717
Returned	15,737	6,495	Inc.	9,242
Net output	13,172	12,697	Inc.	475
December 21 to March 20—				
Gross output	80,667	53,309	Inc.	27,358
Returned	38,566	20,911	Inc.	17,657
Net output	42,099	32,398	Inc.	9,701
Total outst'd March 21	962,792	804,687	Inc.	158,105

ELECTRICAL EXHIBITION. FROM MAY-2 TO MAY-31-

Edison Magnetic Ore Separation.

A great deal of public interest attaches to the work which Mr. Edison has been doing for some time past in magnetic ore separation, and the general curiosity on the subject will be satisfied at the approaching Exhibition, where Mr. Edison will kindly loan a model built for him by Mr. Sigmund Bergmann, which illustrates admirably the fundamental principles of the process. This model will be kept running by a small motor, and the iron will be continuously separated from the crushed rock in full view. Mr. W. S. Mallory, the manager of Mr. Edison's mining work, is sending to the Exhibition samples of crushed rock in its various stages, as well as samples of the separated ore, and of the briquettes which are sent to the furnace. He is supplementing this with some 4 or 5-ton masses of rock, which Mr. Edison takes bodily out of the hillside, by means of huge excavators, and the magnetic condition of these ponderous masses will be shown and tested by magnets. Around the exhibit will be placed photographs illustrative of the scenes at the mines themselves, and the whole will constitute one of the most instructive demonstrations possible. This valuable exhibit will be placed along one side of the Concert Hall of the Garden, in company with a number of very interesting special features which have already been arranged for.

OBITUARY

Daniel Andrews.

The death is announced of Mr. Daniel Andrews, president of the Hamilton, O., Gas Light and Coke Co., and the Hamilton Electric Light Co. He had not long been a resident of the city, but had made himself prominent and respected. The main cause of death was pneumonia. He was in his sixty-seventh year, and leaves a wife and four children.

Edward B. Knowles.

Every one in the electrical field will feel deepest regret at the terrible bereavement that has fallen suddenly upon Mr. E. R. Knowles, the well-known electrical engineer, in the sudden death of his son, Edward Knowles, aged only 20. The two were out together on Sunday morning at Bensonhurst, Long Island, wheeling, when the handle bar of young Mr. Knowles's wheel became loose, and he was thrown, breaking his collar bone and injuring the brain. He was taken home by his father in a carriage, and died during the afternoon. The youth was himself an electrician and had done work of great promise in various directions, particularly in the branch of arc lighting, in which he had made several valuable improvements, now in actual use.

LEGAL NOTES

Litigation on Alternating Current Motors.

THOMSON-HOUSTON CO. VS. WAGNER CO.

We are informed that suit has just been brought in the U. S. Circuit Court, Southern District of New York, against the Wagner Electric Manufacturing Company, by the Thomson-Houston Electric Company. The bill of complaint alleges infringement of the Thomson alternating motor patent No. 430,-328. The first claim of this patent reads as follows:

"1. The herein-described method of operating an alternating current motor in which the rotation is produced by the reaction between the field and a locally-closed armature circuit carrying currents induced from the field, consisting in organizing or connecting the motor armature circuit so that it may receive an initial impulse of rotation, and upon the attainment of a predetermined speed changing or modifying such connections, so as to put the armature coils on locally-closed circuit."

The Wagner self-starting single-phase motor is started by placing the armature in series with the field coils and at running speed the commutator is short-circuited. It is understood that the suit is directed particularly against this motor.

Firman Telephone Switchboard Patents.

We are in receipt of the subjoined item from the Western Telephone Construction Co.: "The attorneys for the Western Electric Company (Bell telephone manufacturers) having published a statement, over their signature, which, by inference, indicates that the Firman patent covers all forms of multiple switchboards, and that this patent was upheld in their favor in a recent California suit, we desire to publicly announce that the Firman patent does not, in any manner whatsoever, affect the multiple transfer system of the switchboard of this company. We challenge a single particular in which the Firman patent claims refer to our devices."

THE STOCK MARKET

Steady but Nervous.

Though much beset by war worries, the stock market has shown remarkable strength and while it would rally very emphatically on news of peace, it may be doubted whether it would go much lower if war were actually declared, for then the wearing uncertainty would be over. Meantime general trade continues good, with almost every condition full of encouragement.

During the past week, 25,459 shares of Western Union were sold at prices between 85½ and 84¾. Of General Electric, 17,270 shares were sold, down to about 32. In Boston, American Bell Telephone advanced from 241 up to 250 on sales of 804 shares. New York Edison advanced from 120 to 124.

Copper is quoted at 12 cents; heavy steel rail, Eastern mill, at 18 per ton. It is said that managers of the large steel works are beginning to express fears as to a coming scarcity of Bessemer pig iron.

PAUL BOURGET. No one who is interested in the best contemporary French literature can afford to miss the series of sketches and stories by Paul Bourget, which will begin in The Living Age for April 2. These sketches have been but recently published in France, and this is their first appearance in English dress. They are translated for The Living Age by William Marchant. They are extremely clever and characteristic.

ELECTRICAL MATERIAL of all kinds in large quantities has lately been purchased by the U. S. Government, chiefly for purposes of coast defence. Gen. A. W. Greely, chief signal officer, wants more immediately.

TRADE NOTES & NOVELTIES

Western Electric Column and Tuerk Ceiling Fans.

THE Western Electric Company's column fans, illustrated in Fig. 1, have but two speeds, 150 and 175 r. p. m., and are made with or without polished red birch tables, all metal work being finished in polished brass or oxidized copper. The motors are furnished with a switch, while the lights are controlled by a switch placed on the under side of the table. The tables can be furnished either square or round and are four feet in diameter.

Special attention is called to the Tuerk alternating current fan motor, shown in Fig. 2, which is furnished with two blades and is designed to be operated on a current of 60, 125 or 140 cycles, at 52 or 104 volts. This motor will be furnished finished in bronze, Bower-Barff, nickel, brass or white and gold. All shafts are mounted on self-oiling bearings. A switch is provided for starting and stopping the motors. By a very ingenious device the angle of the blades may be so shifted that the wind may be blown downward towards the floor or upward towards the ceiling. The motors are of the reduction type. A reduction in speed is obtained by the introduction of leather-faced friction wheels by means of which the motors are rotated at a slower speed than that of the armature; this device enables the use of a highly efficient, high speed, alternating current motor, obtaining all of the desired results of the slow speed fan.

A very handsome catalogue has been issued, describing in detail all of these motors and will be furnished upon application.

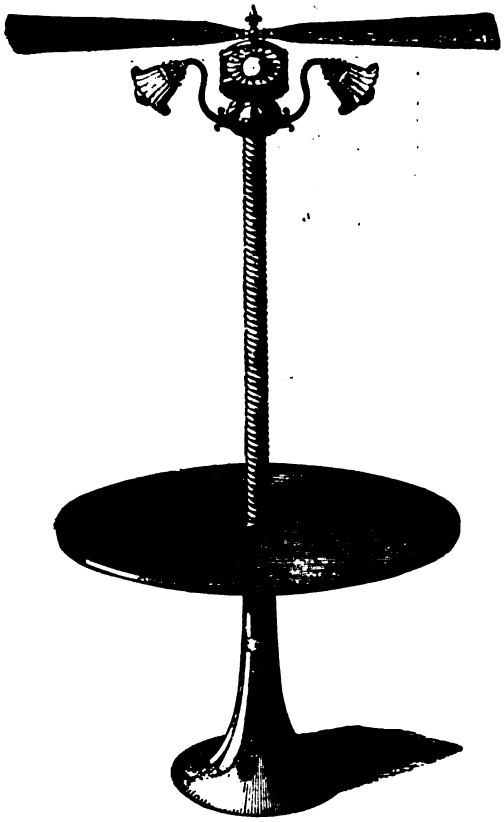

FIG. 1.—W. E. COLUMN FAN.

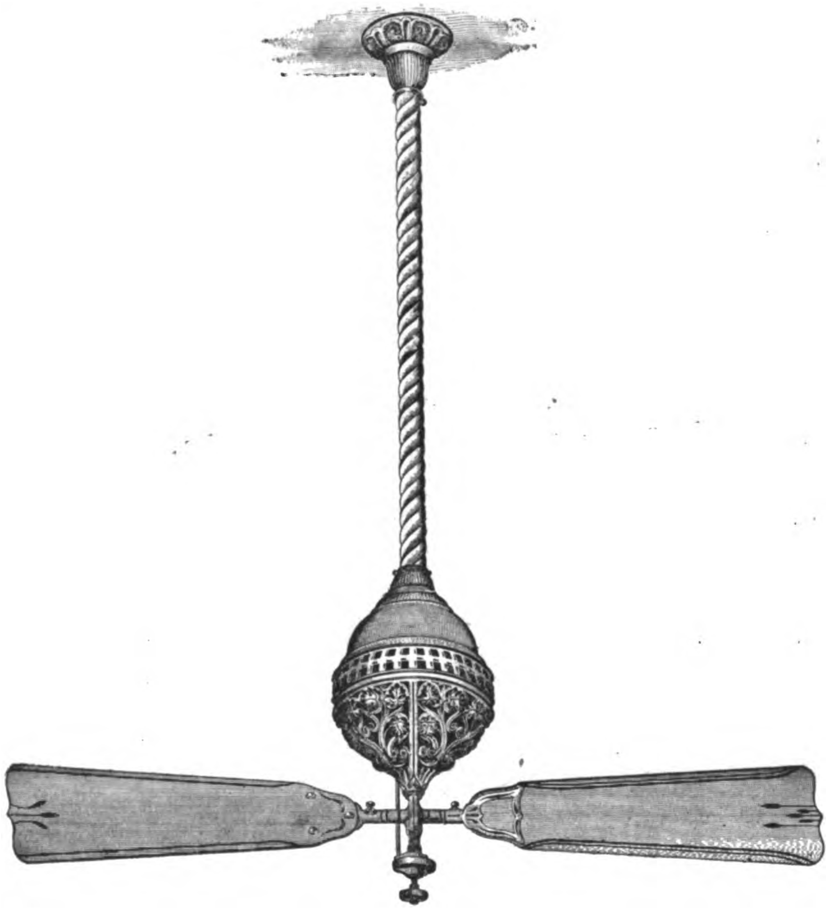

FIG. 2.—W. E. "TUERK" ALTERNATING CURRENT CEILING FAN.

PERU ELECTRIC MANUFACTURING COMPANY, Peru, Ind., have orders enough on hand to keep them extremely busy. Their porcelain insulators are finding an excellent market in both this and foreign countries.

Huge New Foundry For the General Electric Co.

THE General Electric Company, in view of the constantly growing demand for apparatus of its manufacture, has decided to make a large increase in its manufacturing facilities. On March 25, the company placed contracts for the construction at its Schenectady works of a new foundry, which will be one of the largest in this country. The present foundry has been for some time entirely inadequate to meet the demands upon it, and considerable work has been passed on to the admirably equipped foundry which the company has at Lynn. The work to be done has, however, grown even beyond the capacity of both the Lynn and Schenectady foundries, working overtime, and all is now to be concentrated in the new foundry, construction of which is to be begun immediately.

The building will be of brick, 500 feet long and 140 feet wide, with an "L" 100 feet by 120 feet. The latter will be used as a cleaning shop. Besides these main buildings, a number of sand sheds, several smaller buildings for the storage of foundry material, and a new pattern storehouse 200 feet long, 60 feet wide and two stories high, will also be erected. All combined, the floor space occupied will be about 12,000 square feet. Plans are also under consideration for a new machine shop 650 feet long by 165 feet wide, but the appropriation for this has not yet been authorized.

The buildings will be erected on the property which the General Electric Company recently purchased from the Gilbert Car Works. It lies to the west of the present works and parallel with the Erie canal. The foundry will be built several hundred feet from the canal and will be in close proximity to the sand sheds and pattern storehouse. Every precaution will be taken to eliminate risk from fire; indeed, the pattern storehouse will be made as absolutely fireproof as possible. The foundry as laid out will be a model of the most approved modern practice. Careful thought and study have been given to the matter, and the engineers of the company have drawn on the experience of other companies which have recently constructed foundries. The building will be of imposing proportions and will be in plain view from the New York Central tracks.

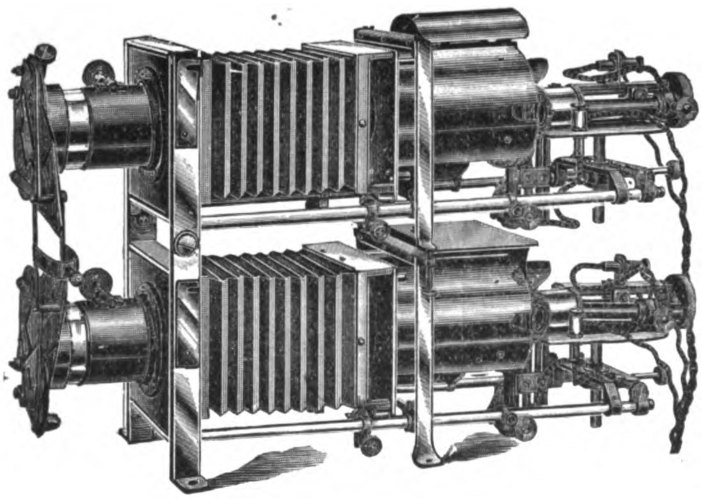
The contemplated machine shop will be built on Central ave-

nue opposite building No. 15, and will be devoted almost entirely to very large machine work. The size of the great generators which the General Electric Company has been manufacturing has of late been increasing until, to-day, a generator of 4,000 h. p. is not now regarded as of unusual size. In fact, generators of 5,000 h. p. are now in course of design, and the demand upon the shop in which the large machinery has heretofore been built has far outgrown its present proportions.

The middle aisle of the new machine shop will be 65 feet wide, with narrower aisles down each side. Electric traveling cranes will be installed to operate along each aisle and a gallery will be built along one side only. All the large machine tools will be removed from their present locations to the new shop, their places being taken by smaller apparatus. The total floor space of this building will amount to not less than 144,250 square feet.

The "Ideal" Electric Light Stereopticon.

AN illustration is shown herewith of the "Ideal" electric light stereopticon, which has been placed on the market by the inventors and manufacturers, A. T. Thompson & Co., 26 Bromfield street, Boston, Mass. The cut gives an excellent idea of its appearance and mechanism. It is one of the most compact stereopticons operated by arc lamps now obtainable, and, being supplied with every known improvement for the correct and rapid exhibition of lantern slides, it commends itself to all who may desire a first-class apparatus at a moderate price. The arc lamps are of novel design and construction, inasmuch as the carbons are arranged on the 90 degree plan, thus securing an increase of nearly 25 per cent. in volume of light over the old way of placing carbons in the perpendicular form. These lamps will burn two hours without changing carbons, and 15 minutes without turning the adjustment wheel. They may be used on either the direct or alternating system of lighting, a double set of gears being fitted to each lamp. The change can be made from one system to the other in one minute. Every lamp is tested for 50 amperes, or five times the usual amount of current passed, and



THE "IDEAL" ELECTRIC LIGHT STEREOPTICON.

the insulation will stand 500 volts indefinitely without injury. The metal hood which nearly surrounds the arc answers a double purpose, inasmuch as it excludes all light from the room and absorbs the heat and dissipates the same to other points than the condensing lenses. Peep holes in these hoods, covered with mica, enable the operator to examine the arc at all times. Another novel feature of this apparatus is the mechanical shutter, by the use of which dissolving effects are produced equal in every way to those obtained by the lime light.

Provision has been made for the use of the microscope and attachment, vertical attachment with lenses, water cells, etc., for chemical and physical laboratory use. The slide carrier and bellows are detachable at the condensing lenses, thus providing space for the introduction of the above mentioned apparatus. The bellows have a sufficient extension for the use of objective lenses varying in focus from 3 to 12 inches. The whole apparatus is finely finished in nickel with burnished brass trimmings, and the general construction is such that with ordinary care it should last a lifetime.

The lanterns are provided with microscopic registering devices, both horizontal and vertical; hence it is possible to exhibit any mechanical effects with perfect accuracy. Messrs. A. T. Thompson & Company will be glad to receive and answer any inquiries with regard to this specialty or any of their other optical and projection apparatus.

The New Edison Fan Motors.

THE problem of designing a fan motor, which shall give good ventilation, and shall also run economically by battery power, is one that has engaged the serious attention of the whole electrical world, and we are pleased to be able to record some very great advances which have recently been made in this direction. The Edison Manufacturing Co., of New York and Orange, N. J., are placing on the market a battery fan outfit which is greatly superior to anything they have produced up to the present time. The 9-inch battery fan outfit, manufactured by this concern, deserves special notice.

The motor is of the Paccinoti ring type, and runs on ball bearings. A series of most elaborate tests (extending over several months) were made, before this innovation was finally decided upon, and the results obtained fully justify the change which

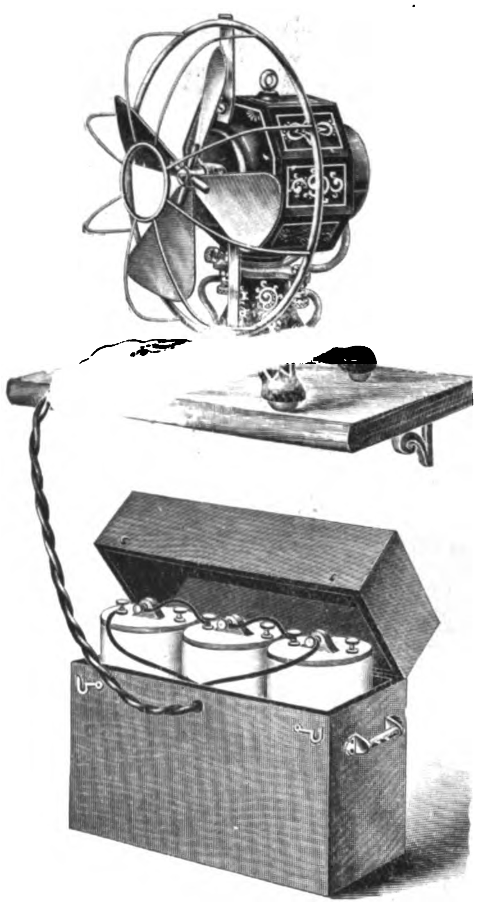


FIG. 1.—EDISON FAN.

has been made. When this outfit was first placed on the market, some five years ago, the motor had a 6-pole armature, and a battery consisting of four Edison-Lalande cells, type "S," in oak box, which ran the motor for 100 fan hours, at a speed of about 700 revolutions per minute, before needing to be renewed.

In the spring of 1897 a new motor was designed, having a Paccinoti ring armature, which was considerably more efficient than the old style motor, as the working current was reduced so that the battery would last for 125 fan hours, and the speed of the fan was increased to about 800 revolutions per minute.

The new ball bearing motor which is now furnished with this outfit takes only 1.75 amperes of current, and runs the fan upwards of 850 revolutions per minute. As the capacity of the battery is 300 amperes hours, it follows that it will run the fan for 170 fan hours before needing renewal. It will thus be seen that the efficiency of the new motor in saving of battery power, is 33⅓ per cent. over that of the 1897 model, and 70 per cent. over that

of the original model. This does not take into account the increase in speed of the fan from 700 revolutions per minute to 850 revolution per minute, which is even more remarkable.

The Edison iron-clad battery fan outfit, manufactured by the same concern, has also been greatly improved. The motor, which carries a 7-inch fan, and is furnished with three Edison-Lalande cells, type "S" (300 ampere hour capacity) in an oak box, has been greatly simplified in construction. The improvement consists in the substitution of a small drum commutator for the disc commutator, formerly used, and the extension of the rear shaft support (carrying the brushes) beyond the iron-clad field, so as to enable the brushes to be easily adjusted. The motor

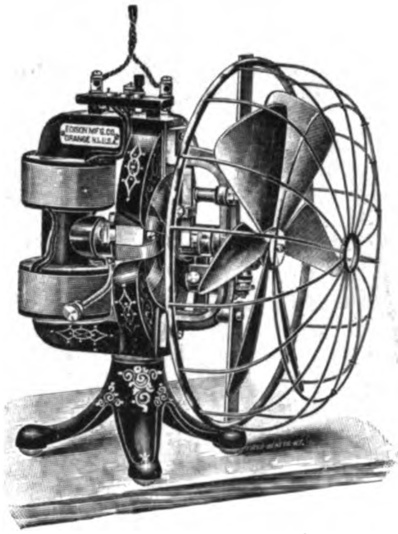

FIG. 2.—EDISON FAN.

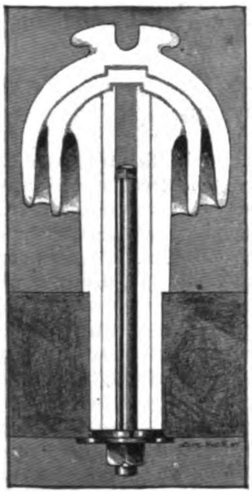
runs the fan at 1,200 revolutions per minute, and the battery will last for 150 fan hours before being exhausted.

The great success that has attended the exploiting of both these battery fan outfits, has induced the Edison Manufacturing Co. to enter the field of the 110 volt direct current fan motors, and they are now placing on the market a very satisfactory fan motor for this current, furnished with 12-inch fan and guard. This motor is similar in construction to the 9-inch Edison battery fan motor, but is furnished with a three-speed switch, running the fan at 1,000, 1,200 and 1,400 revolutions per minute, respectively. The efficiency of this instrument is very high, and the workmanhip of all the outfits is of the very finest grade.

New Style Boch High Potential Insulator.



IN our issue of March 24, we described a method of manufacturing highly efficient petticoat insulators, the invention of Mr. J. W. Boch. The method of "glazing" described in that article has now been applied by Mr Boch in the manufacture of the insulator shown in the accompanying illustration. In the construction of this insulator, porcelain is used for both the body and the post. The petticoat body is made in two or more parts, each petticoat being like an inverted bowl, with the smaller one nested into the larger one. The central portion constitutes a third part of the insulator. These three parts are secured together either during the process of vitrifaction or in the glazing, in order to make it equal in strength to a single homogeneous piece. The supporting post is at its lower end adapted to enter an opening made in the cross-arm, and an annular shoulder is formed on the post to rest on the cross-arm and form a point of support. The vertical opening in the support is of a diameter suitable to receive the metal securing pin which extends up into the post to any desired height, and is secured by a suitable cementing composition. A nut and washer complete the means for holding the whole in place on the cross-arm.

These insulators have been placed on the market by the R. Thomas & Sons Co., of East Liverpool, Ohio, with sales offices at 39 and 41 Cortlandt street, New York. Wherever installed they have given entire satisfaction.

Sprague House Elevators.

The Sprague automatic house elevators are being received with a great deal of favor, and many wealthy men of New York City and elsewhere are placing them in their houses. The machine embodies a number of highly ingenious features in its method of control, which is entirely automatic. By means of its devices, the machine may be operated from any floor, or from the car itself. By merely pushing a button from any floor, the car is brought to that particular floor without any further manipulation of the controlling apparatus, and when a door is opened, it is impossible to operate the machine from any other point, or until the car has reached its destination, and the landing door is finally closed. While the car is in operation it is impossible to operate any of the buttons aside from the one initially connected, and there is also a mechanical locking device at each door preventing its operation except when the car is at the corresponding landing. The simplicity and absolute safety of this machine is the great reason for its success.

The M. R. Rodrigues Mfg. Co.

The M. R. Rodrigues Mfg. Co. has recently been incorporated under the laws of the State of New York to manufacture electrical motors and appliances, and will be located after May 1 at Nos. 10 to 14 Whipple street, Brooklyn. The company is formed by Mr. M. R. Rodrigues and Mr. A. T. S. Clarke. Mr. Rodrigues is well and favorably known because of his long connection with the electrical field not only in the manufacturing line, but in many electrical associations; and it is due to his untiring energy that he has been able to build up for himself a very profitable manufacturing business during the number of years he has been engaged in this work. The new quarters of the company are beside the old location and are about twice as large as the old factory. A lot of machinery will be installed, and with the additional room secured the manufacturing end of the line will be prosecuted vigorously. Prompt shipments are assured.

The Peru Electric Manufacturing Co.

In 1892 a company including many of the most influential citizens of Peru, Ind., was organized with a capital stock of $100,000, for the purpose of manufacturing and placing on the market a line of electrical supplies, and it was known as the Peru Electric Works. In the latter part of 1893 fire wiped away the large porcelain building, and as the Dow plant across the railroad track was idle an offer for the buildings was made and accepted. After some alterations and repairing the move was made and the force of employés increased. Each year the company has seen its business grow larger and new buildings go up to accommodate the demand for more room. Although it now has one of the largest and most complete institutions of its kind in the country, it is again preparing for the erection of another large building. This will be twenty-five feet wide and seventy feet long. Forty-five feet of the building will be one story high, while to the other twenty-five feet a second story will be added. The structure, which will be located north of the large two story brick building in which the clay bins and press room are at present, will be made of brick with a fireproof roof. The clay bins will be moved into the new building and the space made vacant will be filled with porcelain presses. The two story part of the new building will be made fireproof to contain all the dies used in the business.

A porcelain kiln, surrounded by an ironclad building thirty feet square and one story high, has just been completed and will soon be pressed into service. This makes five kilns for the works. At present the company is enjoying a boom in trade and has a force of at least a hundred persons at work. The plant is one of the most thriving in the city. The present officers are: J. O. Cole, president; C. H. Brownell, vice-president; R. H. Bouslog, secretary and treasurer; R. A. Edwards, J. O. Cole, C. H. Brownell, J. G. Brackenridge, William Levi and William B. McClintic, directors.

The Diehl 1898 Electric Fans.

THE Diehl Manufacturing Co. of Elizabethport, N. J., who were the originators of suspended fans using a self-contained motor, have for many years maintained the high standard of their product by the introduction of improvements whenever possible. Their desk fans, illustrated in Fig. 1, were placed on the market last season, and met with instantaneous success. They are of the highest efficiency, due largely to an unbroken magnetic circuit, which is a special feature. They are constructed of the finest material throughout. The armatures are built of laminated iron assembled on steel shafts, the coils being wound with double silk covered wire; the commutators are cut from one piece of pure copper and insulated with India mica; the bearings are made of Tobin bronze, are self-aligning, and are lubricated by means of wick oilers; the switches and speed regulators are mounted on steel frames, and the finished motors are as complete in all respects as 5-horse power machines of the most improved type. Each outfit is beautifully finished in rich black japan, tastefully ornamented. The blades, guards and trimmings are of polished brass, nickel or japan, as desired. These specifications also apply to the bracket fans, illustrated in Fig. 2, which may be clamped and adjusted at any desired angle to the side wall, the adjustment being effected by the wing nut at the bottom.

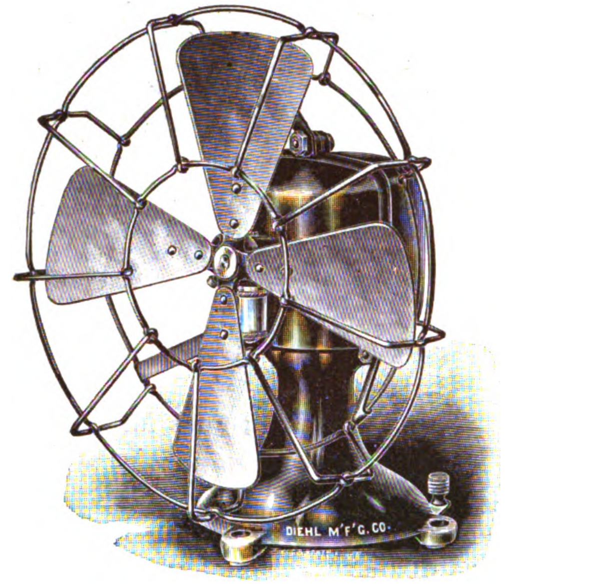


FIG. 1.—DIEHL PERFECTED DESK FAN.

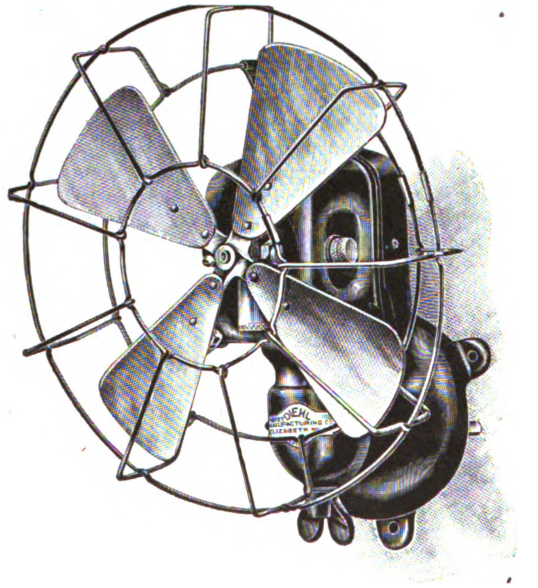

FIG. 2.—DIEHL ADJUSTABLE BRACKET FAN MOTOR.

The ceiling fans, shown in Fig. 3, present an attractive appearance and are so constructed mechanically and electrically as to appeal especially to the careful and intelligent purchaser and insure continuous service and freedom from repairs. The Diehl Company have issued a very handsome catalogue and price list, which illustrates a great variety of desk, bracket, ceiling, column and exhaust fans of any size, and wound for any voltage.

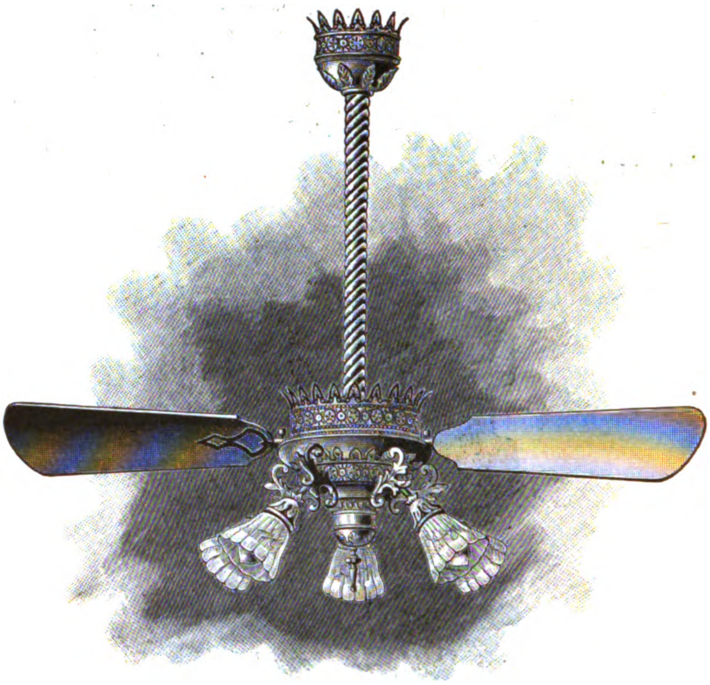

FIG. 3.—DIEHL ELECTROLIER FAN.

Tariff on Electric-Light Carbons.

The proper duty on arc light carbons under the present tariff law was the subject of a hearing on Friday last before the Board of Classification of the United States General Appraisers, in New York City. The law prescribes a specific duty upon carbons for electric lights at the rate of 90 cents a hundred, and various importers have had carbons made about a yard long, to be cut into proper lengths after being imported. The government maintained that on a thirty-six-inch carbon a duty should be levied at least three times as great as that on a twelve-inch carbon. This, however, is offset by the absurdity of such a scale in other directions, regardless of the quality or value of the carbon. Decision was reserved.

Large Orders for the Walker Co.

Among the foreign orders recently received by the Walker Co. may be mentioned: Twenty double No. 3-S street car equipments, three single No. 3-S equipments and eighteen double No. 3-N equipments for Paris, besides four 150 kilowatt belted generators with two generator panels. Messrs. Bagnall & Hilles, of Yokohama, have ordered two 25 kilowatt direct connected generators for Singapore.

Recent domestic orders include two 150 kilowatt three-phase synchronous motors for the Lachine Rapids Power Co.; a 700 kilowatt alternator, single phase, for the Buffalo and Niagara Falls Electric Light and Power Co.; two 400 kilowatt belt driven generators for the Syracuse Construction Co.; and one 120 kilokatt belted generator for the Northern Electric Co., of Baltimore. The Norton & Attleboro Railroad, of Attleboro, Mass., has purchased four double No. 4-A-S and two double No. 5-S equipments, besides a 250 kilowatt direct connected railway generator. Besides the generator above referred to, the Northern Electric Co., of Baltimore, have ordered 100 Walker arc lamps, making in all 300 in three months.

The company has also recently taken a contract from the Government to build three disappearing gun cariages for 8-inch rifles; they are to be of the Crozier type, 1896 model.

A New General Electric Enclosed Arc Lamp.

A MODIFICATION of its enclosed arc lamp has recently been perfected by the General Electric Company, which, while preserving the essential features of its well-known direct and alternating current lamps, with enclosed arcs, substitutes a flared porcelain reflector for the outer globe. The mechanism of the lamp is similar to that of the standard enclosed arc lamps, but the use of the reflector instead of the globe, allows a large amount of light which otherwise would be absorbed in the outer globe, to be thrown down by the reflector and thus utilized. Calculating this absorption of light at from ten to thirty per cent., the single globe lamp allows of the utilization of just so much of the total light from the arc, as well as that which is reflected. In cases in which the direct light from the arc is not objectionable and a general diffusion of the light not absolutely desirable, such as in cafes, hotels, restaurants, etc., the single globe is peculiarly adapted.

In designing the lower part of the frame, care has been taken

MODIFICATION OF GENERAL ELECTRIC ENCLOSED ARC LAMP.

to render it both light and delicate and yet sufficiently rigid to withstand ordinary usage, without interfering to any extent with the passage of the light or casting heavy shadows. It is highly nickeled, and thus, during the daytime, when the light is not needed, the ornamental appearance of the lamp is not detracted from. The inside of the porcelain shade is highly polished and gives a good reflecting surface. It is interchangeable and can be used with either direct or alternating current enclosed arc lamps. By an arrangement of the lower rim of the cover of the mechanism, the reflector may be substituted for outer globe of the double enclosed arc lamps. As in the direct current double globe lamps, a simple adjusting coil allows of the use of 5, 4½ or 4 amperes. By using a reflector instead of the globe, a very satisfactory light may be obtained from this lamp with a current of only four amperes. A reactive coil in the alternating lamps allows of adjustment for any line voltage between 100 and 120 volts and frequencies of 60 and 125 cycles.

The economy in carbons is the same as that obtained in the double globe lamps, and in addition the lowering of an outer globe is done away with. The globe in which the arc is enclosed is protected by wire netting.

M. B. WHEELER ELECTRIC CO. of Grand Rapids, Mich., has been formed with a capital stock of $25,000, for the manufacture of electrical supplies and specialties.

C. & C. Electric Co.

We are advised that the C. & C. Electric Company, of New York are, in spite of the war scare, enjoying one of the busiest seasons in the company's history, and that their extensive works at Garwood, N. J., are kept running night and day on orders.

During March the C & C Company took a large number of most gratifying orders of impressive proportions—enough to keep them busy for several months. Many of their recent orders have come from abroad, and the company is building up an export business which is the envy of many of its competitors.

Orders for Ball Engines.

The Jones Bros. Electric Co., Cincinnati, O., will increase their plant by the addition of a 250 h. p. tandem compound engine direct connected to a 150 kilowatt dynamo. The engine will be furnished by the Ball Engine Co., Erie, Pa., and the dynamo by the Westinghouse Electric Mfg. Co., Pittsburg, Pa.

The New Electric and Gas Light Co., of Guthrie, Oklahoma, are adding a large addition to their steam plant, and have recently ordered from the Ball Engine Co. a 175 h. p. engine, boiler and heater.

The Horne Building, of Pittsburg, which was burnt about a year ago, is being rebuilt on a more magnificent scale. The electric light plant will be large and complete. Two vertical cross compound engines, furnished by the Ball Engine Co., are being installed. These engines are direct connected to Siemens-Halske Electric Co. generators, and the whole outfit is a very handsome one.

Large Building Contract In St. Louis.

Contracts have been placed for the mechanical and electrical equipment of the large mercantile building now being erected on the north side of Washington avenue, between Ninth and Tenth streets, St. Louis, by the Commerce Realty Company. This building has been leased for ten years, beginning June 1 next, to the Hargadine-McKittrick Dry Goods Company. The contract for steam equipment, which has been awarded to the Kupferle Bros. Mfg. Co., covers three 150 h. p. water tube boilers with down draft furnaces, the Paul system of steam heating, two 300 h. p. Hoppes feed water heaters, boiler feed, house and air pumps, and the complete system of pipe work. One hundred and twenty-five pounds pressure will be carried.

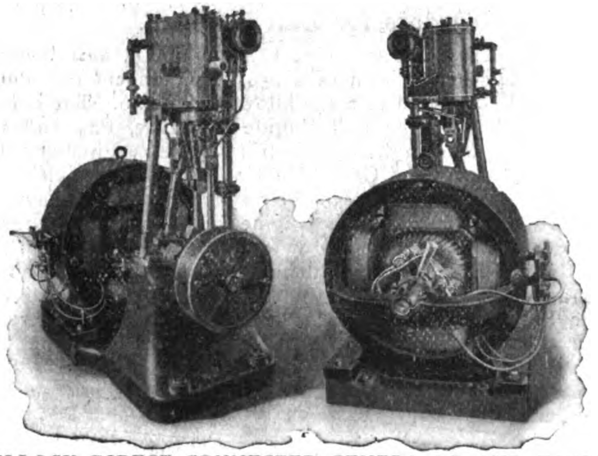
The General Electric Co. secured the contract for electrical equipment, covering three compound Imperial engines of 120 h. p. each, direct connected to three 75 kilowatt direct connected dynamos, speeded 260. There will be about 600 16 candle power incandescent lamps in the building, and 200 long burning enclosed arc lamps. The electrical plant will also furnish current for driving the entire elevator plant, the contract for which has been awarded to the Sprague Electric Company, of New York. This contract covers two passenger elevators, six freight elevators, one dumb-waiter and one ash-hoist. The distribution will be on the 220-volt two wire system for all the different kinds of service. The elevators are to be run from the same generator units as the lighting system. This installation represents a distinct advance in St. Louis in modern installations of this character, and its performance will be watched with interest. Messrs. Eames & Young are the architects. They have associated Messrs. Bryan & Humphrey with them as consulting engineers.

THE RAPID INCREASE in the number of indepenendent telephone exchanges has made the telephone supply business a very important item in the business of all of the electrical supply companies. One of the items used by the telephone companies for which there has been quite a large demand is that of rubber-covered telephone cables. The Paranite telephone cables which are being sold in the West by the Electric Appliance Company are securing a very high reputation among telephone people. The Electric Appliance Company are in a position to make most prompt delivery on these telephone cables for the reason that they represent the only rubber-covered wire factory located in the West. The Electric Appliance Company are enabled to ship any ordinary order for special telephone cables from their Indiana factory within a very few days after its receipt. The company are always pleased to submit samples at any time of what they are producing in this line.

CATALOGUES.

Bullock Bulletin on Direct Connected Generators.

THE Bullock Electric Mfg. Co. have just issued a new bulletin on their engine type of direct connected generators. The bulletin follows in general design their former bulletins,



BULLOCK DIRECT CONNECTED GENERATOR AND FORBES ENGINE.

consisting of eight pages devoted to handsome illustrations and short description. Their direct connected generator appears on the front page. The general design of this machine is similar to that of their standard multipolar machines, in that it consists of a circular yoke carrying inwardly projecting pole pieces of laminated soft steel of the highest magnetic permeability. The pole pieces are cast welded into the frame, thus forming a more substantial joint, both mechanically and magnetically. This generator is built in six standard sizes ranging from 25 to 200 kilowatts.

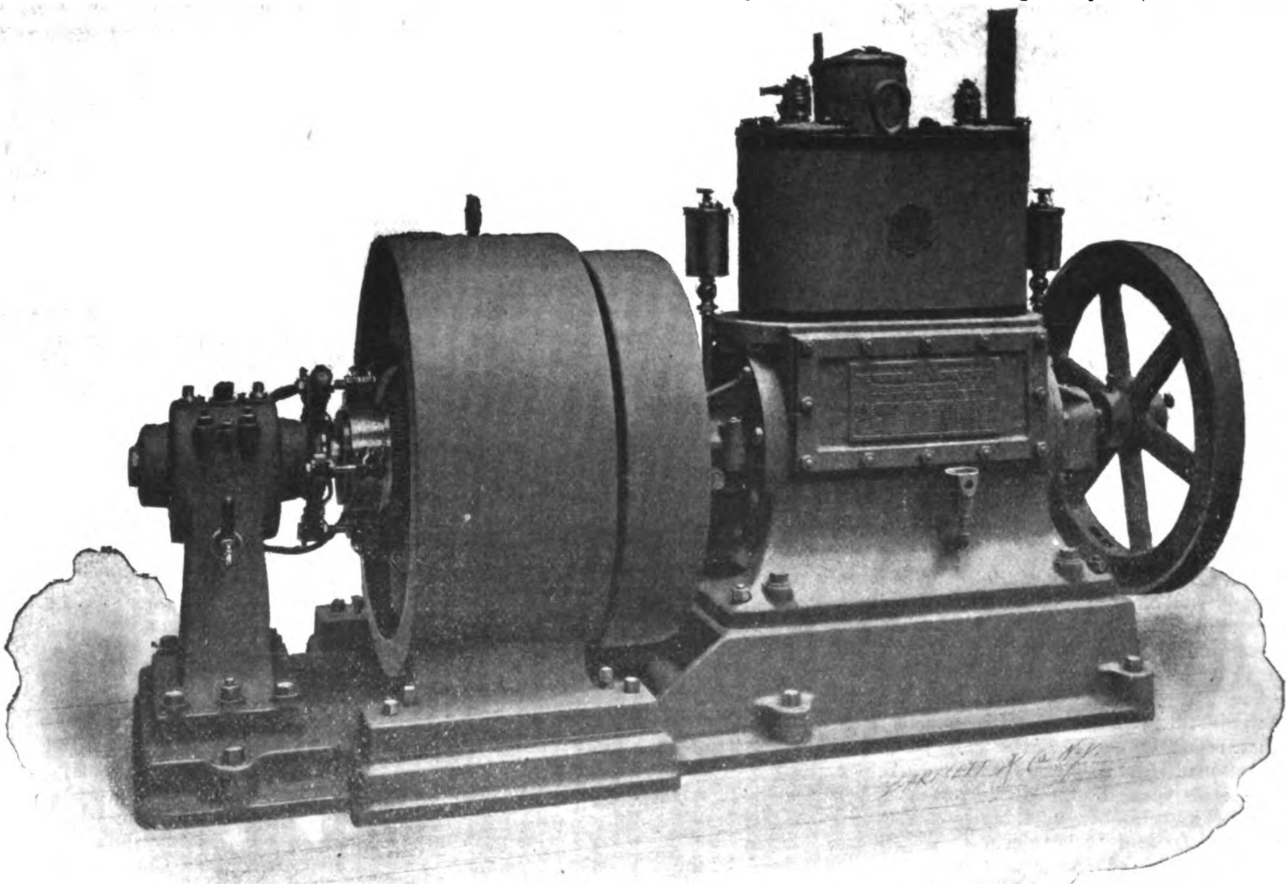
These generators are compounded to compensate for a drop of potential in the line. The shunt and series coils are wound on separate forms, and are removable at will. The field coils are so wound that they are open for the circulation of air, and perfect ventilation assured. All the compound coils are wound with bare copper, which is carefully insulated, and makes it practically impossible to burn out. The laminated core is made up of thin laminated plates of soft, well annealed steel. The periphery of the armature is slotted, and the windings are held in position by means of retaining wedges of hard wood driven into the notches near the top of the slot, longitudinally with the armature. This is peculiar to the Bullock machines.

On the third page of this bulletin are illustrated two views of the Forbes engine and Bullock generator. Under the illustration is given a table showing the sizes of engines and their corresponding sizes in generators. Another attractive generating unit displayed in this bulletin is the Bullock generator and Westinghouse engine.

In the course of a month a new bulletin will be published on motors for machine tools and their machinery.

New Johns Catalogue.

The H. W. Johns Manufacturing Company has issued a new and revised edition of its "Electrical Materials" in the compact and attractive form which has become well known to its customers and the trade at large. While the size of the book remains the same, the introduction of much new matter has greatly increased the number of pages. More space than heretofore is devoted to Vulcabeston in its various forms; the company's business in repair parts requiring more detailed information concerning such stock pieces as commutator rings, controller and motor parts, bushings, field magnet spools, etc. These are listed, with sizes and descriptions accompanying the illustrations. Many additions have been made to the list of trolley line materials. Among the new devices are splicing sleeves and ears



BULLOCK'S DIRECT CONNECTED GENERATOR AND WESTINGHOUSE ENGINE.

for "Fig. 8" wire, the Hartford section insulator or "break," trolley wheels, the "All-Steel" trolley bracket arms, designs for third-rail insulators, etc. Several more pages than heretofore are devoted to the "H. W. J." electric car heaters and the Electrotherm heating pad. Reductions in prices are noticeable throughout.

The New Headquarters of the Edison Mfg. Co.

AT Broadway and Twenty-sixth street, New York City, the Edison Mfg. Co. have just opened superb headquarters for handling their large and varied line of product, in the handsome new St. James Building. They have entered upon occupancy of the entire corner store and basement, giving them a total floor space area of over 8,000 square feet. The store is of lofty pitch, bisected by massive gilt columns, and has been finished in oak, with Pompeiian red finish for the wall, and heavy red carpets for the floor. There are roomy show windows all around, and the front entrance is beautifully recessed from the street, with a graceful glass awning thrown over it and part of the sidewalk. Right above the awning is the magic autograph, "Thos. A. Edison," executed in large fac-simile on a dark background, shining out at night in miniature incandescent lamps. Nothing could be more attractive than the exterior; nothing more satisfactory than the interior, and this was evidently the opinion of the crowds which availed themselves of the housewarming invitation on Saturday night last, between the hours of 7 and 9, when Manager J. W. Gladstone, and Mr. W. E. Gilmore, from the Edison laboratory works, were on hand to welcome their friends and extend the courtesies of the occasion. Not only were the show windows full of choice apparatus, but there were shown in their first form many of Mr. Edison's inventions, such as his vote recorder, phonograph, etc. These were inspected by thousands of people, who also listened to the phonographs at work around the store with fine cylinders on them, or else inspected the Edison X-ray apparatus, the Edison projectoscope, the Edison electro-medical apparatus, the Edison cautery transformers, the Edison fan motors, old style and new, the Edison-Lalande batteries, and a host of other beautiful appliances.

At the rear of the store is an elegant suite of offices, finished in oak and frosted glass, for Mr. Gladstone and the clerical part of his staff, with every convenience for the swift dispatch of work. In the rear of the store is a freight elevator, and the basement affords excellent facilities for the receipt and shipment of goods. Mr. Edison and his company are to be congratulated on securing such an admirable store, in a location that has no superior in the city for the exhibition and sale of standard electrical apparatus of the nature made and handled by the concern.

WESTERN NOTES

THE WALKER COMPANY claims that its type "S" Solenoid Blow-out Controller is the most popular one the company has ever placed on the market. The controller departments of their factories are turning out very large numbers of the type "S" apparatus.

AMERICAN ELECTRIC TELEPHONE CO., of 171-3 South Canal street, Chicago, have secured a very large contract covering apparatus for a 3,000 instrument outfit for the Saginaw Valley Telephone Co., which is to put in an underground system at Saginaw, Flint, Bay City and West Bay City. This plant was selected after a very exhausive test of apparatus on the market, and after a committee had visited several large "independent" exchanges.

WESTERN ELECTRIC COMPANY has brought suit against the Millheim Telephone Company for infringement, in the U. S. Circuit Court at Pittsburg.

WESTERN ELECTRIC COMPANY has issued a very interesting and handsome catalogue on its fan motors. Some of the details contained in it are given in our Trade Notes this week.

WESTERN ELECTRIC COMPANY have recently made a number of shipments of interior conduit and fittings. They always keep on hand a large and complete stock of conduit to meet all demands.

NON-SPARKING BRUSHES. The constantly increasing demand for W. E. non-sparking brushes shows that there is a necessity for an article of this description. The most stubborn case of sparking at the brushes and commutator is conquered by the use of the W. E. non-sparking brush, and it is highly recommended by many of the best dealers in the country.

SWINGING TREE INSULATORS. There has been some criticism by several men living north of Chicago in regard to the Western Electric Company advertising a swinging tree insulator when the snow was on the ground. But the circulation of the electrical trade journals extends from the most southern point of the civilized world to the most northern, and now is the time of year for at least 50 per cent. of the central stations in the United States to look after their outside lines and prevent them from coming in contact with the trees.

NAGLE & BALL, of Chicago, have been engaged as the electrical engineers of the Grand Rapids Board of Public Works, for the purchase or construction of an electric light plant. They are to receive $5,000, for all services, including plans and specifications, inspection and supervision. The firm is composed of A. F. Nagle and W. D. Ball.

DAWSON CITY, N. W. TY. The American Telephone Co., of Chicago, have just expressed to Seattle, a 100-number "Express" style switchboard, complete, with 100 telephones, to be used by a company at famous Dawson City, center of the gold rush. This apparatus is all packed in very narrow boxes, so that it can be placed on sleds and carried over the passes quickly and successfully.

WESTERN ELECTRIC CO. has recently opened a branch office in the Security Building, St. Louis, in charge of Mr. Irvine S. Jackson, who will devote his entire attention to the business in that city and the surrounding territory. This office will be furnished with every convenience for meeting the large requirements of the trade, both as regard prompt delivery of goods and satisfactory prices.

NEW ENGLAND NOTES

C & C. The location of the Boston office of the C & C Electric Company, of New York, has been transferred from the old quarters at 63 Oliver street, to more modern and commodious quarters at 19 High street, corner of Federal. The company's customers will be welcomed at the new offices by Mr. Wm. F. Palmer, who has recently succeeded Mr. H. A. Howard as manager for the company for New England.

MR. S. B. CONDIT, of the firm of L. A. Chase & Company, Boston, visited the New York market this week.

NEW YORK NOTES.

LUNDELL HORSELESS MOTORS. The Sprague Electric Company are meeting with considerable success in placing their Lundell Horseless Carriage Motor on the market. Quite a number are in use in this country, and very many abroad, particularly in England. In London, the Lundell Motor Equipment has recently been placed upon the mail van service, and excellent results are reported. Since the vans have been so equipped, it is stated that none have ever been behind time—a record which no other vehicle ever succeeded in obtaining.

SPRAGUE ELECTRIC CO. announce that the advance sales for their Lundell fan motors are greater than in any previous season. Doubtless their handsome new catalogue will serve to increase orders, as a great variety of handsome designs is therein displayed to great advantage.

McCARTHY BROS. & FORD have been appointed agents for the Sprague Electric Company for Buffalo, N. Y. The headquarters of the house are in the fine new Caxton Building in that city. Other appointed agents are Morton, Reed & Company, for Baltimore, Md.; Walker & Kepler, for Philadelphia; and Pettingell-Andrews Company, for Boston.

WALKER COMPANY has recently secured a very handsome and commodious suite of offices on the sixteenth floor of the Commercial Cable Building, 18-20 Broad street, New York. The suite includes a private hall, general offices, private offices for the officials of the company and all the latest conveniences for the modern transaction of business.

ADVERTISERS' HINTS

THE WALKER COMPANY, Cleveland, O., are calling attention to the several styles of electric locomotives they build for all classes of service, including mining locomotives for surface or tunnel haulage. Their New York office is now at 20 Broad street.

THE WESTINGHOUSE MACHINE CO., Pittsburg, Pa., have increased their facilities for the manufacture of gas engines and are beginning to get the better of their orders now. Some sizes are in stock for prompt delivery.

THE PRATT & WHITNEY CO., Hartford, Conn., advertise vertical and horizontal adjustable multi-spindle drilling machines in nine sizes and a full line of machinery for manufacturing bicycles, guns and sewing machines.

THE CROSBY STEAM GAGE AND VALVE CO., Boston, Mass., are well prepared to ship without delay all orders for valves for low or high pressures, and steam engine indicators, gage testers, vacuum gages, single bell chime whistles, feed water regulators, lubricators, etc.

THE ELECTRIC LAUNCH CO., Morris Heights, New York City, advocate the use of electric passenger boats as a paying investment at street railway parks and pleasure resorts. They stimulate traffic.

WHEELER REFLECTOR CO., Boston, Mass., state that they have made a careful study of abstruse problems in reflector lighting of all kinds and can now prescribe the special style of reflector to suit each particular case.

THE WESTINGHOUSE ELECTRIC AND MFG. CO., Pittsburg, Pa., advertise Wurts' lightning arresters for alternating and direct current circuits.

THE ELECTRICAL EXCHANGE, 166-174 South Clinton street, Chicago, are now the agents for the Standard Thermometer and Electric Co., the manufacturers of the famous Upton "Midget" enclosed arc lamps.

THE HOPPES MFG. CO., Springfield, Ohio, guarantee their live steam purifier to keep boilers clean and free from scale. Their new catalogue may be obtained for the asking.

EDWARDS & CO., 144th street, New York, are advertising electro-mechanical vibrating or single stroke gongs for exposed places, to operate on electric light or battery circuits.

HUGO REISINGER, 11 Broadway, New York, reiterates the warning to those who infringe his rights in using the "Electra" trade-mark on inferior brands of carbons.

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, Ill., say that all the trouble incidental to short circuits can be avoided by the use of "Paranite" insulated wire.

THE BERLIN IRON BRIDGE CO., East Berlin, Conn., offer an iron roof for sale at a bargain. Owing to business reverses of the original purchaser the terms at which it is offered make it a bargain worthy of consideration.

THE PACIFIC ELECTRIC CO., La Crosse, Wis., have just brought out three new things, "Karsline," "Inline" and "Playtone," which they say are needed by every electrician. They will tell exactly what they are, their price, etc., on request.

RILEY BROS., 16 Beekman street, New York, are selling stereopticon slides illustrative of the most recent happenings, such as the Maine disaster, the Cuban war, etc. The plain slides are sold at 40 cents each, and the supercolored at $1.00.

THE GENERAL ELECTRIC CO. advertise alternating current enclosed arc lamps and mention in detail some of their numerous advantages.

THE SAFETY THIRD-RAIL ELECTRIC CO., Temple Court Building, New York, are introducing a third-rail system, of which a model is on exhibition at their offices. The system is fully described on another page of this issue.

MACHADO & ROLLER, 203 Broadway, New York, advertise "A. E. G." incandescent lamps.

C. S. KNOWLES, 7 Arch street, Boston, Mass., is carrying a full line of "Imperial" transmission insulators as well as his replete stock of supplies.

VITRO CHROME CHEMICAL CO., 42 Milwaukee street, Milwaukee, Wis., offer "Vitro Chrome," an indestructible incandescent lamp color, which they claim to be equal to natural glass in appearance and durability for inside and outside decoration.

THE CUTLER-HAMMER MFG. CO., Chicago, state that there are now over 10,000 of their high-class rheostats in use. The number constantly grows.

THE GARVIN MACHINE CO., Spring and Varick streets, New York, call attention to a screw machine that will make duplicate parts and pieces in a manner that will surprise the user. They have a complete stock of metal-working machinery ready for delivery.

THE EDISON MFG. CO., Broadway and Twenty-sixth street, New York, are ready with their 1898 models of battery fans and outfits. They are designed to run 150 hours on one charge of battery.

THE COLUMBIA INCANDESCENT LAMP COMPANY, Olive street, St. Louis, Mo., request that a test be made of the "Columbia" before annual lamp contracts are renewed.

THE C & C ELECTRIC CO., 143 Liberty street, New York, say that every detail of their machines is carefully worked out and perfected.

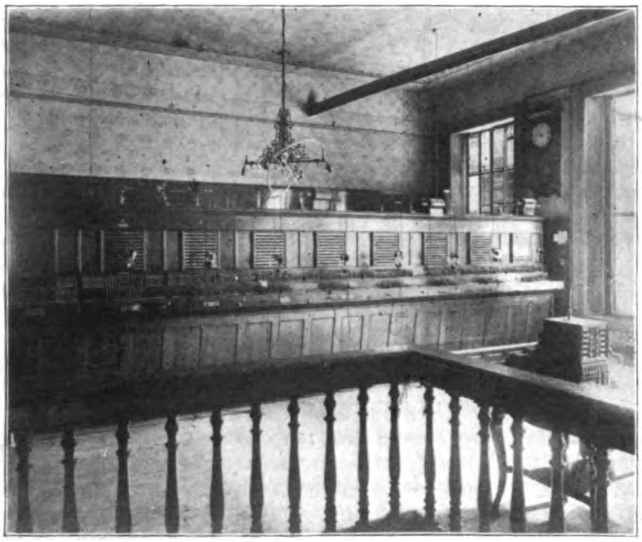
Vol. XXV. APRIL 14, 1898. No. 519.

TELEPHONY AND TELEGRAPHY

The Independent Telephone Exchange at La Crosse, Wis.

BY J. R. CRAVATH.

THE independent telephone business is by far the most active branch of electrical industry in the United States to-day. It is now in the active construction period that corresponds to the electric railway in 1890. New capital is constantly going into the business, new exchanges are being established, those already established are being extended, and in all quarters the independent movement is gaining strength. That some costly mistakes have been made, just as in the beginning of other branches of electrical work, must be admitted, but in the great majority of cases the investments in independent exchanges have proved to be wise, and the sympathy and support of the telephone using public has been with the movement.

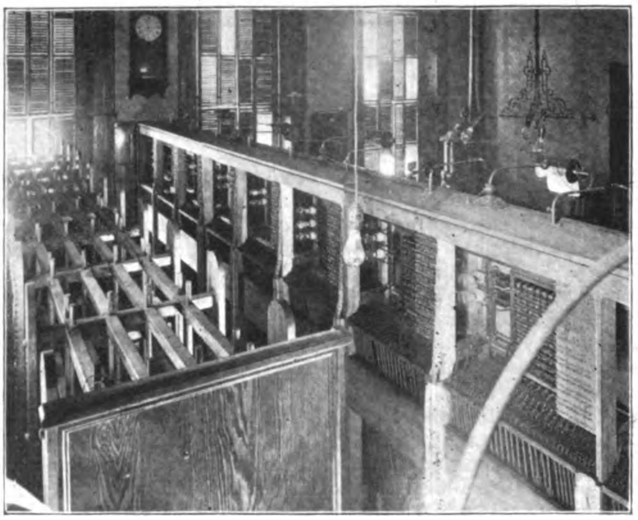


LA CROSSE TELEPHONE EXCHANGE; FRONT VIEW OF SWITCHBOARD.

The number of first-class paying independent exchanges scattered over the country is proof of the possible success awaiting enterprises of this kind. The La Crosse Telephone Co., of La Crosse, Wis., is one of these, and as it presents some interesting features from both a technical and an investment standpoint, it is worthy of an extended description.

La Crosse is a prosperous city of about 30,000 inhabitants. The exchange now has nearly 700 subscribers, and this is constantly on the increase. The Bell exchange has about half that number, many of whom are getting free service. The La Crosse Telephone Co. is composed of La Crosse business men, and has the following officers: Capt. I. H. Moulton, president; W. W. Cargill, vice-president; William Lohmiller, secretary and treasurer. Geo. R. Johnston, formerly of the Western Telephone Construction Co., who installed the exchange for that company, is now superintendent. Although chartered for several years, it was not until Oct. 1, 1895, that the exchange was put in operation. The rates (which have never been altered or cut since the exchange started), are $2.50 per month for business houses, and $1.50 for residences.

The accompanying engravings show the front and back of the exchange switchboard, which is divided into nine sections, one of which is for toll lines (at the extreme right) and one of which is left blank for future growth. This board is the product of the Western Telephone Construction Company, and is what may be called a multiple plug, in distinction to a multiple jack switchboard. It is well known that the complication and expense of a multiple jack switchboard as commonly employed in old line exchanges is something tremendous, though it has, up to within the last few years, been considered a necessity. It is interesting therefore to examine carefully anything that offers a simpler method of handling the business of a large exchange. The switchboard is wired for a complete metallic circuit throughout. In front of each operator is a panel of annunciator drops connected with 100 subscribers. These drops are a combination drop and spring jack. Thus when a subscriber rings, a shutter falls in front of the jack. The operator in inserting the plug in the jack to answer the call, restores the shutter by the insertion. The drop is thus made mechanically restoring rather than electrically restoring; and the wiring is simplified not only by the absence of electrical restoring wires but by the combination of the annunciator and spring jacks in one device. The subscriber's wires are connected only to the corresponding annunciator jacks on one section of the board instead of to all the sections as in a multiple jack board. Each operator can of course reach one section on each side of her. The connections out of her reach are made by an operator as follows: Directly in front of her is a set of plugs which are to be used for making connections with calling subscribers and also a set for connecting with called subscribers, as on all boards. Now, in multiple with these latter plugs are connected transfer plugs located at the right and left hand of every third operator along the board. Thus, suppose a board has seven sections for seven operators designated from right to left as at La Crosse, A, B, C, D, E, F, G. The cord circuits of certain plugs on A section will be connected with transfer plugs on sections D and G. There are also push buttons with which the A operator and D and G operator can converse, and so on; each operator is in communication with enough operators so that every number on the board can be reached. Supposing that A operator receives a call from a subscriber who wants a number on section C out of her reach, for example 354. A operator calls D operator, who can reach C, and tells her to connect a certain transfer plug (the other end of which plug is already connected to the calling subscriber on section A), to number 354. As soon as D operator does this, operator A rings for 354 just as if the called subscriber were on her own section, because the cord circuits on her section are in multiple with the transfer plugs on the other sections. The transfer plugs are of course never touched by an operator until she is told to use them by the operator to whose section they belong. When the conversation is ended and the subscribers ring off, the clearing out drop in the cord circuit connecting the two subscribers falls, showing the operator on section A that



LA CROSSE TELEPHONE EXCHANGE; REAR VIEW OF SWITCHBOARD.

the conversation is ended. She disconnects, but the plug is still in number 354, section C, and to notify operator C that she must disconnect 354, the following arrangement is devised: The sockets into which the plugs fall when not in use are wired with an incandescent lamp circuit which is closed only under

these conditions, namely, when an answering plug is out and a transfer plug is in a jack. So when A operator, in the case under consideration is notified by the clearing out drop to disconnect, the plug is pulled out and let fall back into its socket. This closes the lamp circuit and lights two lamps, one on section D, notifying that operator to disconnect, the other on section A, telling that operator as long as the operator at D has failed to disconnect. For this purpose two 26 volt lamps are used in series supplied from 110 volt lighting mains and connected in series with a resistance to reduce the voltage. These lamps both go out as soon as both operators disconnect.

The chief operator's board has a lamp for every section of the main board. Each lamp is so connected that it is lit whenever an annunciator drop is down on a section. It might be thought that these lamps would be lit all the time, but such is not the case, for the operators, aware of this tell-tale, make very quick work of answering a drop. The chief operator can bridge in her telephone and transmitter on any operator's circuit either for conversation or listening to learn what is going on.

Transmitters in the exchange are supplied by gravity batteries. The ringing is done with a ½-horse-power Crocker-Wheeler motor generator giving 60 volts alternating on its secondary and run from a 110 volt circuit.

A metallic circuit with common return is used for all instruments connected to this exchange. The common return wire is No. 6 copper, and the individual subscriber's wires are iron.

The force usually employed consists of 12 operators, 2 linemen, 2 men on general work, and 1 manager.

Practical Features of Telephone Work.—V.

BY A. E. DOBBS.

IN regard to the size of the return wire, there is a wide diversity of practice even among the various Bell companies, who have perhaps greater uniformity of engineering practice than is possible among independent companies. In some places a No. 4 wire has been run out to serve 500 subscribers; in others, No. 0 is used for half that number. Some ground the wire at the office and various other places; some only at the office, which is better. Some don't put on any ground at all, better still; while others do not even bring the wire into the office at all, cutting it off at the pole outside and letting the talk come in over the other lines, which is not a very good way, though there may be circumstances that justify it.

One company puts its subscribers in groups of from 20 to 40, using a No. 10 wire for each group.[1]

An acquaintance, unable to determine the question for himself, took a trip to a distant city to consult an eminent electrical engineer on the matter, and as a result of his advice strung six No. 6 copper wires to return the back talk of about 250 sub-

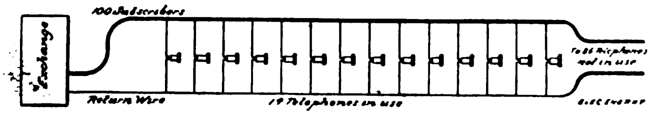


FIG. 14.

scribers; a clear case of wasted copper, for one of these wires would have answered just as well. And the worst of it was that there was more cross talk in that exchange than in any other modern exchange I have ever seen, and he cannot be convinced to this day that the cross talk does not come from an insufficient amount of copper. Had he studied more about cable and switchboard work he would have had better success.

By the way, his city friend was a man who ranks high in his profession, but he has spent all his life designing motors and superintending street railway installations, and can hardly be regarded as a telephone expert, even though he does frequently "get his name in the papers."

There is an impression among the new men in telephone work that a bulky return wire is necessary and if there is any cross talk the wire, already larger than necessary, is reinforced, and —the cross talk is still with them.

The fault will generally be found in the switchboard or cables, and a return the size of a trolley feeder would not help matters. But more of this later.

Before going further let us do a little work in simple arithmetic. Let us take, for example, a lead of 100 subscribers and try to get at the resistance of the return:

The resistance of the drop, say	150 ohms
Resistance of bells	80 ohms
Resistance of average line, including capacity, etc.	70 ohms
Total	300 ohms

This may be put down as the lowest average resistance of a line when not in use. Of course the resistance of drop and bells will vary over wide limits.

Of the 100 subscribers the occasions will be rare when more than six pairs of plugs (12 subscribers) are in use, but let us say seven pairs (or 14 subscribers).

On the lines in use we have:

Two induction coils of 250 ohms each	500 ohms
One ring off drop	100 ohms
Two receivers	150 ohms
Line resistances, etc.	100 ohms
Total	850 ohms

One coil however by its self induction throws back on the line almost as much current as it receives, but the self induction of the other coil will raise its resistance, in almost the same ratio so that 500 ohms for the two coils is not far out of the way.

As will be seen by reference to Fig. 14, the subscribers on a common return system—or a grounded system for that matter—are all connected in multiple.

We have shown fourteen telephones connected to the exchange

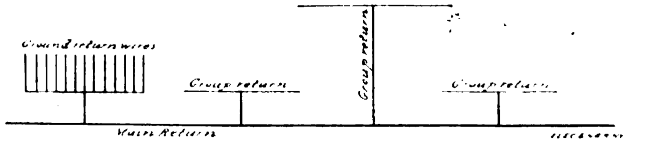

FIG. 15.

in actual use, the lead of 100 subscribers being for convenience's sake, represented in the form of a cable.

It will be seen that the current will not only come in on the return wire, but will distribute itself to every other wire in the system in proportion to its resistance. Now let us see:

Total return resistance of 14 lines in use $= 850 \div 14 = 67$ ohms

Total return resistance, 86 lines not in use $= 300 \div 86 = 3.5$ ohms

Now, if the average subscriber's distance from the central office be three-quarters of a mile, a return wire that will balance the resistance of the 86 lines not in use should help us out all right.

By looking over a table of resistances for copper wire we find that No. 9 B. & S. has a resistance of a trifle over 4 ohms to the mile, therefore the resistance of three-fourths of a mile of this size would more than balance the conductivity of the lines.

Our return now therefore would be:

86 lines	3.5	ohms
Common return	3	ohms
Combined return and 86 lines	1.6 +	ohms

From this we will see that the relative conductivity of these 86 lines, and the common return, is 1.6 to 67 ohms, a proportion of 42 to 1.

The one part left for these 14 wires is divided up among the 13 other wires, or in other words, the 14 lines, if their resistance is approximately the same, receive $\frac{1}{42 \times 14}$ or $\frac{1}{588}$ of the current.

We can therefore lay down the following rule for getting at the size of the common return:

1. Find the resistance of one line for the average distance from the exchange, including that of the drop and bell magnets.

2. Subtract from the total number of lines, the number of lines which may be in use at one time. (14 in 100 is a good number.)

3. Divide the resistance of one line by the number of lines so left, and select a wire, whose resistance to the centre of distribution will be equal to this quotient.

[1] As copper is nearly always sold by the Brown & Sharp gauge all copper wire will be given in this size; also, iron wire is generally sold by the English standard or Birmingham gauge (B. W. G.). The B. & S. gauge runs about two sizes larger for the same size of wire. Thus No. 10 copper is about the same size as No. 12 iron, while No. 12 copper matches No. 14 iron, etc.

In order to have reliable service it is not generally advisable to use a copper wire smaller than No. 10 B. & S., except on leads having not more than 25 wires.

When wires on different leads are joined together, the wire towards the office end should be increased in proportion unless it is already sufficient to do the work, and when they are all joined together at the office pole a wire equal in cross section to all of them, brought to the switchboard or bus-bar.

In places where electric light and power induction is unusually severe, it may be necessary to divide the subscribers into groups of from 20 to 40 lines each, keeping the subscribers in each group as close together as possible, carrying the return from each group back to the office.

Where this is the case and two or more return wires run on the same pole, they should be kept as close together as possible and frequently transposed, or—this is merely an hypothesis of the writer—it might be well to run out one wire large enough to supply all the subscribers and have the return wire for the different groups kept separate, and connected to the main-return on much the same principle as the feeder and main system in electric light wiring, Fig. 15, in which the main return wire should be heavy enough to leave but a small resistance between the different groups.

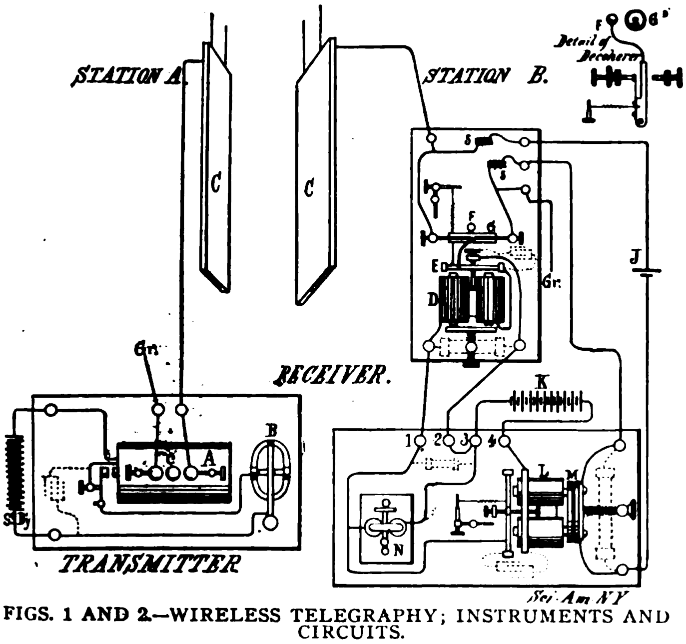
In some exchanges it is customary to ground the common return wire at the office, but I think that a better balance is preserved by not grounding. Still there are places where it is very inconvenient to run two wires, and being able to run a ground is quite an advantage.

In making house connections use porcelain knobs instead of brackets, for brackets on the side of a house are always unsightly, and well glazed porcelain affords insulation enough for all practical purposes, but do not cover the side of the house with them, for two or three are nearly always enough.

While on this subject we may as well say that wires from the pole to the house should ont be drawn very tightly, as it is not often necessary, and a tight side wire will not only pull the pole out of line, but is apt to be a "hummer."

Clarke's Apparatus for Wireless Telegraphy.

ON March 25, Mr. W. J. Clarke gave a practical demonstration in this city before the New York Electrical Society, of the Marconi system of wireless telegraphy, which proved highly successful. Mr. Clarke made use of his own apparatus, which have been perfected after months of experimenting. The apparatus illustrated below embody the latest improvements



FIGS. 1 AND 2.—WIRELESS TELEGRAPHY; INSTRUMENTS AND CIRCUITS.

based on recent investigations, and are commercially suitable to the requirements of wireless telegraphy in this country. Mr. Clarke showed the apparatus illustrated in Figs. 5 and 6 and diagrams, Figs. 1, 2 and 4, by reference to which it will be seen that both the transmitting and receiving stations are shown in Figs. 1 and 2, station A being the transmitting and stations B and C the receiving. The transmitter shown at station A gives the most efficient kind of spark for the purpose. The coil is fitted with an ordinary vibrating make and break, constructed so as to give just the requisite number of interruptions. A special Morse key, B, is placed in the primary circuit, and the condenser is so connected as to kill the spark at the key contact as well as at the vibrating contact. Mounted on the upper part of the coils are three solid brass balls, C, the centre one being stationary, and the outside ones adjustable, so that their

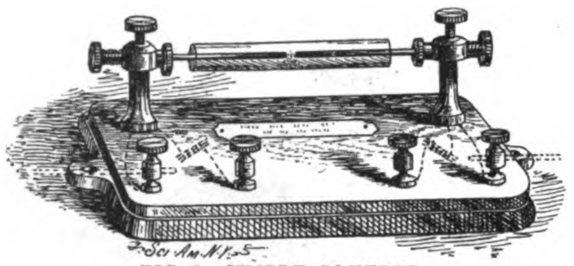


FIG. 3.—SIMPLE COHERER.

distance from the centre ball can be regulated at will. The two outside balls are connected to the terminals of the secondary coil, as are also the binding posts shown at the side of the coil. It will now be readily seen that when the key, B, is depressed, sparks will pass between the balls, and will immediately cease when the key is released. By means of the two binding posts at the side of the coil, one terminal of the secondary coil is connected to earth, and the other terminal to the large metallic plate, C, which should be placed high in the air. The coil may be operated by any suitable battery, but a small storage battery is very much to be preferred.

The receiver at station B consists of two separate instruments, the Clarke coherer relay being mounted on one base, and the

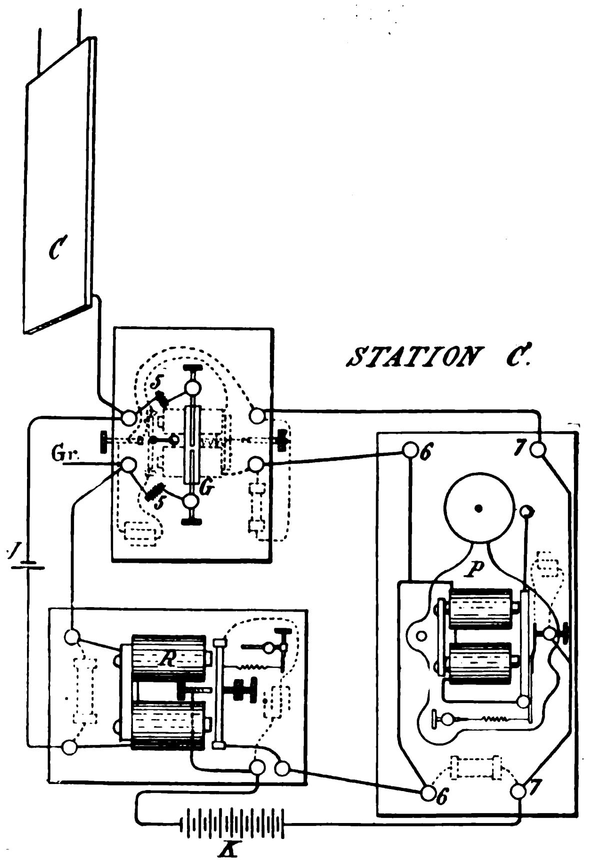

FIG. 4.—WIRELESS TELEGRAPHY; APPARATUS FOR BELL SIGNALS.

polarized receiving relay and sounder upon another. The coherer, G, is a small glass tube made of selected glass, and carefully fitted with two metallic plugs, whose distance from each other in the tube can be readily and accurately adjusted by means of the screw and spring adjustments shown at each end of the tube, Fig. 3. The space in the tube between the plugs is partly filled with specially prepared metallic powder, and the

two plugs are connected to the binding posts shown, through the small choking coils, 5. These posts are connected to the magnets, L, of the receiving relay through the main battery, J, and binding posts of polarized receiving relay as shown.

One terminal plug of the coherer, G, is connected to earth as shown, and the other terminal plug is connected to the large metallic plate, C, which like the plate at the transmitting station should be placed high in the air. When the powder between the plugs in the tube is lying in its normal condition its resistance is extremely high, often reaching 20,000 ohms, but when the key of the transmitter at the distant station is depressed, electric waves are sent out into space; these waves travel from the plate, C, of the transmitter to the plate, C, of the receiver, and finally reach the powder in the tube, G. Under the action of the waves, the particles of powder in the tube immediately cohere, and their resistance instantly drops down to between 7 and 25 ohms, which great decrease in resistance permits the current from the battery, J, to pass through the circuit, and energize the magnets, L, of the polarized receiving relay, which in turn operates the sounder, N, using the large local battery K. When the powder in the tube once coheres, it remains in that state until the tube receives a sharp tap, when operates the vibrating hammer as shown, which it will be seen will keep constantly tapping the tube as long as the key at the distant station is depressed, the powder refusing to decohere as long as the waves are passing through it; but the moment that the key at the transmitting station is released, the last tap of the vibrating hammer, F, decoheres the powder, and thus practically opens the circuit of the battery, J. In order that the apparatus may work properly, it is necessary that every part of it be very carefully constructed, and a wide range of adjustments provided; this last is especially true of the decohering apparatus, which must be so arranged that the vibrating hammer can be adjusted to strike the tube with just the necessary strength of blow. It is also found necessary to have all the magnets wound to a very high resistance, and their terminals provided with resistance coils of still higher resistance; and as the sparks produced by the contacts of the polarized receiving relay, and also by the vibrating contacts of the decohering apparatus, send out waves which affect the coherer, these sparks must be almost entirely suppressed by the use of suitable condensers in the bases of the instruments. This set of apparatus is used for the transmission of Morse signals to moderate distances only, but for longer distances it is simply necessary to use a much larger and properly designed induction coil in connection with the transmitter.

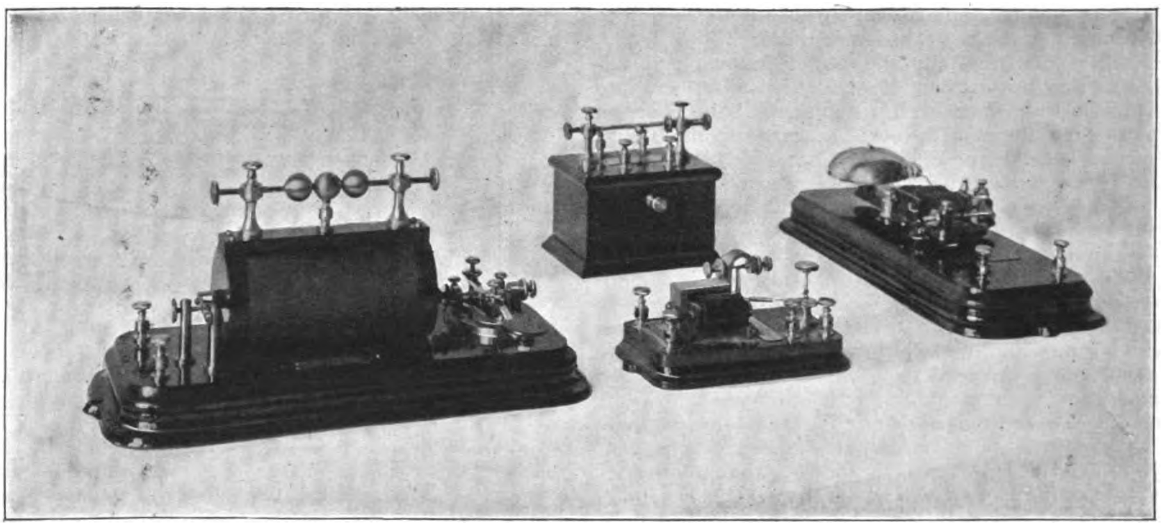

FIG. 5.—INSTRUMENTS FOR TRANSMITTING ELECTRIC SIGNALS BY MEANS OF WIRELESS TELEGRAPHY.

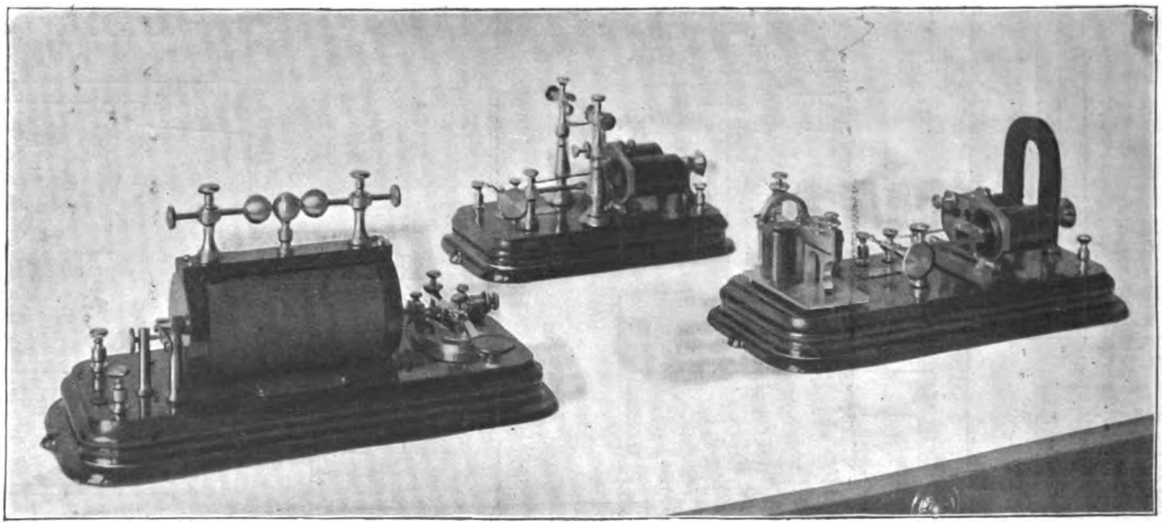

FIG. 6.—INSTRUMENTS FOR TRANSMITTING MORSE SIGNALS BY MEANS OF WIRELESS TELEGRAPHY.

the powder instantly de-coheres and its resistance rises again to an extremely high point. In order that Morse signals can be transmitted it is necessary, of course, that the tap on the tube be automatically accomplished. In order to secure this the decohering magnets, D, are provided and placed in multiple with the magnets of the sounder, so that the magnets and decohering apparatus will operate simultaneously; the decohering magnet

It is frequently desirable to dispense entirely with Morse signals, and this is especially true on shipboard or in places where there is much noise and where a much louder signal or a visual signal is required. To meet these requirements a much less expensive set of apparatus has been designed. The transmitter is

precisely the same as in the preceding case, but the polarized receiving relay, R, is much smaller and is not provided with as sensitive adjustments, it having been found that for bell signals they are not necessary. The sounder is entirely dispensed with, and is replaced by a high class vibrating bell, shown at P in the diagram of receiving station C, shown in Fig. 4. The bell is so arranged that it can be adjusted to work in unison with the vibrations of the decohering apparatus. The Clarke coherer relay in this case is mounted on top of a mahogany box which contains the decohering magnets, resistance coils for bridging the terminals and also condenser for suppressing the spark at the vibrating contact, as fully shown in the diagram at station C. The plugs in the cohering tube, G, are provided with the same adjustment as in the more elaborate set. The working of the apparatus is perfect in every respect. When required, the vibrating bell, P, can be replaced by an incandescent lamp which can be readily turned on and off from the distant station. It is certainly extremely interesting to place the transmitter of this set in one room and the receiver in another and then listen to the vibrating bell ring out loudly in response to every impulse of the waves. No ground connection, however, or air plate is required for either set of apparatus when the distance between the transmitter and the receiver is comparatively short. For the benefit of those who wish to experiment, and perhaps endeavor to build their own apparatus, a simple coherer is provided which is shown in perspective in one of our half-tone illustrations and in detail in the lower engraving. The outer binding posts of this coherer are intended to hold two light rods of metal of equal length in projecting out on either side. These rods or wings are necessary when it is desired to transmit to any considerable distance without using the earth connection or air plate. We are indebted to the "Scientific American" for illustrations.

ELECTRIC LIGHTING

Statistics on English Electric Lighting Plants.—I.

BY CLAUD P. D'OYLY.

FOR some years past the electrical papers have contained accounts of the new stations going up at different times in various European cities and have presented beautiful photographs showing pressed brick stations, underground conduits and transformer stations with glazed tile interiors. We have heard of and seen the concentric cables and the ornamental steel arc lamp poles and we have admired and have sometimes wished that we had the time, not to mention the money, to put in such elaborate work.

There are in England, Scotland and Ireland at the present time about 134 commercial and municipal electric lighting companies. About two-thirds of these use the alternating current and one-third direct current and storage batteries. About one-half of the plants are owned by the municipal authorities, as they are able to borrow money at a very low rate and are frequently willing to operate the plant at a loss for a few years. The public generally favor the idea that the four principal items affecting the general comforts of the taxpayers, viz., water supply, artificial lighting, drainage and highways, should be under immediate control of the local authorities.

Owing to the low price of labor they have not paid as much attention to coal and ash handling machinery as we have, but in other directions their money and energy have been expended prodigally to make work which shall be permanent and shall show small deterioration. I shall attempt in these few brief articles to show some of the effects of this expenditure on the operating expenses and net and gross earnings as far as they are comparable with results we have in this country. I have taken as examples stations of moderate output in smaller towns, of which Pontypool, with a population of 5,800, is the smallest, and Birmingham is the largest. The London stations do not give any data which can be compared with that of any similar stations in any other part of the world, unless it be New York; and here the interest required for money and the cost of labor change the conditions very much, so that really there is no comparison possible.

In considering plants in England, it must be remembered that at present the country is "money poor," that is to say, trustees and others having money to invest have the utmost difficulty in securing investment which will net 2½ per cent. per annum, and which investments will run without being disturbed or paid off, a reasonable length of time. British government bonds, which pay 2¾ per cent., and which in a few years will only yield 2½ per cent., are selling at 112, and any of the municipalities can borrow money at 3 per cent., usually from local investors, without any trouble about paying commissions to bankers and without advertising. The conditions of demand are very stable; they do not have new cities build up outside the present limit, necessitating doubling the voltage, additional stations, rotary transformers, etc. A plant can be laid out in the best method, and plans made for the very distant future; people do not offer inducements to manufacturers to move a plant with some thousand of employés into new neighborhoods, thus changing the whole nature of the locality. City councils do not grant franchises to new companies to occupy the territory already covered by a chartered lighting company; there are no State Legislatures to reduce the price received for the light in order to gain popularity; and the Board of Councilmen do not threaten to build a municipal electric plant every time the lighting contract comes up for renewal. There is not so much hostile feeling towards incorporated companies, and as long as the rates for current are being reduced and the service is being bettered, people are satisfied even if the stockholders are receiving 8 or 10 per cent. for their money. A very large number of the users of electric light are people of small incomes, who can use it for less money for a month than they can use gas, even at 65 cents per 1,000 feet. Many rich people who make no account of small expenditures still use the gas exclusively, chiefly because they object to tearing up the whole house for putting in the wires. All these people will be users of electric light later on.

One feature which rather attracts attention from an American engineer is the cheerful way in which in their report the boards of electric light companies refer to the loss from operation for the past year, without having had disastrous accidents or any cause for excessive outlay. They calmly congratulate stockholders on the improvement; the loss was reduced so much for the current year, etc.

In table 1 herewith will be found some figures on some plants which I took some time to look up. They show some of the results of operation, and which will prove of interest as demonstrating various financial results.

Kingston-on-Thames has an alternating plant which Mr. J. H Preece designed, using Siemens Bros.' apparatus. They have spent $112,500 up to the last return and have an income of $12,000; after allowing to the sinking fund $2,535, there is a loss of $6,900 for the year. In addition their report shows that their current cost to deliver 9.54 cents per k. w. h. and was sold for 8.36 cents, with a total of lamps installed of 5,384, each lamp 8 candle power.

Bristol, a city of 220,000 inhabitants, has expended $500,000 on a plant of about 1,300 h. p. and has 38,000 8 candle power lamps wired on the circuits. After allowing for depreciation for the year, $18,000, the result for the year was a financial loss of $25,000, but of this the interest is charged on the sum borrowed to put in the plant, and allowance is made for the sinking fund. The average price obtained was 10.62 cents per k. w. h. and the cost of same was 6.38 cents. This plant has been in operation two years. It serves on the city circuits 105 arc lamps, which should be credited against the net loss for the year. Newport, Monmouthshire, has an alternating station which has cost $172,000 and has 7,300 8 candle power lamps on the circuits; the revenue was $7,160 and the sinking fund allowance was $3.520; current was generated for 6.42 cents and was sold for 7.22 cents per k. w. h.; the net loss for the year was $7,000. Taunton, a Devonshire borough, of 18,000 inhabitants, takes pride in the fact that it is a pioneer in electric lighting among the smaller cities. It is the headquarters of Messrs. Newton & Company's manufacturing establishment, and shows a very capable and truly commercial spirit in its management and the results attained. There are about 7,200 8 candle power lamps wired on the circuits and 56 public arc lamps, and the plant shows a steady increase each year. There is $90,000 invested in the plant. The revenue for twelve months was $11,500, and after making the different charges, including $2,600 for depreciation, the net loss was $2,225. The price received for current averaged 9.78 cents, and the current cost to deliver 7.82 cents per k. w. h.

Bedford has an alternating plant capacity 420 k. w. and has 17,000 8 candle power lamps wired on the circuits. The cost of the plant has been up to date $293,000 or almost $700 per k. w. In the past year the cost per k. w. has been increased about 40 per cent., but it has been done in such a way as to increase the efficiency of the plant, so that where a year ago the current cost 6.56 cents to generate, it now costs something less than 5.76 cents per k. w. h. There is also being invested much money for increased mains and transformers and meters, and the lamps wired in on the circuit have been increased 4,000. Most of this capital expenditure, it is only fair to state, has not yet had a chance to be productive, but should show up well in the report for 1898.

Dover is another town with an alternating station of 325 k. w. capacity and railway generators of 200 k. w. capacity, which have cost in all $270 per k. w. The electric railway has only been in operation a very few months, but it shows that the cost per k. w. delivered will be materially reduced. In 1896 the cost per k. w. sold was 10.26 cents, and in 1897, with four months of electric railway operation, the cost per k. w. was 8.34 cents. The load required for the tramway was 12 per cent. of the total current generated. This might give a hint to some small towns where they are operating separately a small electric light and a small electric railway station, neither of which pays dividends.

Pontypool has a small plant, direct current, with storage batteries, and has 3,000 8 candle power lamps wired; the plant cost $33,000 and has a gross revenue of $4,600; after allowing $600 for depreciation the profit was $912; the current cost 8.96 cents per k. w. h. to generate and sold for 11.82 cents. The population of Pontypool is 5,800, and the plant started in with only 800 8 candle power lamps, but has grown continually and has paid dividends of 3 per cent. annually.

Brighton has a population of 116,000, and has a direct and alternating plant which has cost over $700,000. While the plant has not progressed with the vim of an American plant, there has been a very healthy growth, and the cost to the consumer of current has been reduced under the able management of Mr. Arthur Wright. The station has an output of 1,200 k. w. and has cost about $600 k. w., and is the property of the municipality. There are something like 70,000 lamps wired on the circuit, and the charges are 14 cents per k. w. h. for an average of one hour per lamp per day and 3 cents for all over that. That settles the expense where it belongs, on theatres, and churches, and shops, which only use current at the time of the peak of the load, and it reduces the price below that charged for gas, to householders. The revenue of the Brighton plant is about $90,000 per annum, but has been expanding at a great rate since the council reduced the rate from 6 cents to 3 cents after the first hour. The price received in Brighton for the current averages 9.41 cents per k. w. h. and the cost for generation and delivery of same is 4.72 cents. The operation of this plant would show a large profit under a Board of Directors, but under municipal control much that is clear profit is charged to depreciation, sinking fund, etc.

Bradford, the centre of the woolen manufacturing district, has a direct current plant, which has cost $356,000, of a capacity of 1,400 k. w., about $250 per k. w. The current is generated at a cost of 4.48 cents per k. w. h. and sold at a net price of 9.56 cents per k. w. h.; the lamps on the circuit amount to 38,500. Coal is very cheap at this point, which brings down the cost of manufacture. The highest point for cost of fuel of any of these enterprises was 3.24 cents per k. w. h. and the lowest 1.08 cents; but the conditions are so different as regards supply of coal that an analysis cannot be made, although the Brighton plant is one which is handicapped.

TABLE I.

Town.	System.	Capital to Revenue, to Last Return.	Depreciation and Last Return.	Sinking Fund.	Net Financial Result.	Price per Unit. Av. Price Obtained, Cents.	Cost per Unit, Cents.	No. of Lamps, 8 c.p.

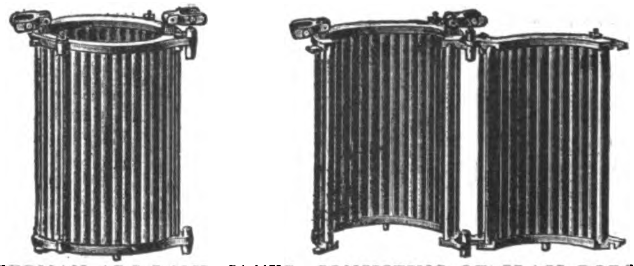
German Arc Lamp Covers for Modifying the Intensity of the Light.

A unique arc lamp cover, which has already found a considerable market in this country, has been introduced and patented by the firm of Schmidt & Westerman, of Hanover, Germany. It is meant to replace and improve upon the use of the ground glass or opalescent globe and consists of cylindrically arranged glass rods as shown in the figures. These glass rods are held in place by two iron rings, which are



GERMAN ARC LAMP COVER, CONSISTING OF GLASS RODS, OPEN AND CLOSED.

grooved so as to receive the rods and are held together by means of wire rods fastened by nuts. The glass rods do not absorb as much light as the opalescent or frosted globes, but disperse and distribute ahe light very efficiently and eliminate all traces of shadow.

The cylinder, consisting of glass rods, can be easily opened, and, therefore, can be cleaned with ease. It may also be mentioned as a special advantage that in case of breakage the entire cover need not be thrown away, but single rods can be replaced. These covers can be fitted to any lamp and can be supplied with any type of reflector or locking device.

FAR ROCKAWAY, L. I. The Citizens' Electric Lighting Co. are to build a new electric lighting plant to supply Inwood, Rockaway Beach and Far Rockaway; also Lawrence, Cedarhurst, Woodsburgh and Hewletts.

HIGHLANDS OF NAVESINK, N. J.—The first order fixed white light at the Highlands, overlooking Sandy Hook, is to be replaced by an electric light showing a white flash of about one-tenth of a second duration every five seconds.

SEOUL, KOREA, is to have a company for electric light and traction, with a capital of $600,000. Mr. H. Collbran, of Denver, Col., has a contract for six miles of trolley construction on the Seoul-Chemulpo Railroad. The Seoul Electric Co. is composed entirely of Koreans, with the governor of the city as president.

MISCELLANEOUS.

Liquefied Air.

BY SOL. D. BENOLIEL, E.E., A.M.
Adelphi College, Brooklyn, N. Y.

THE commercial introduction of liquid air is due to the efforts of Mr. Charles Tripler, who claims to have succeeded in liquefying the atmosphere as far back as January, 1890, but who, until now, has withheld his valuable invention from the public. His compressor is an ordinary steam engine consisting of three cylinders placed in the same straight line, each one being operated by the same piston rod. The air is carried through three degrees of compression, reaching a pressure of 2,000 pounds to the square inch in the third cylinder. The cylinders are all water jacketed in order to remove the heat caused by the high pressures exerted upon the air. From this cylinder the air is allowed to escape partly through a long and very narrow tube of about one-thirty-second of an inch in diameter, and partly through a tube that surrounds it and which serves as a jacket, the whole apparatus being well insulated with a magnesia covering. The air in expanding from this pressure of 2,000 pounds down to atmospheric pressure, does work, and consequently loses heat, but not sufficient to cause the air to reach the critical temperature or that temperature above which no amount of pressure can liquefy it. It is a well-known fact that the more work an expanding gas has to do, provided no heat is communicated from without, the more will its temperature be reduced. Mr. Tripler has ingeniously taken advantage of this fact by the construction of a peculiar valve through which the air must pass after leaving the cylinder, and in doing so a great deal of its energy is used up, resulting in a great drop in the temperature of the air. It is particularly upon the construction of this valve that Mr. Tripler bases his invention. The air flowing through the outer tube or jacket is wasted, serving only to prevent communication of the heat to the inner tube. A short time after the engine has been started a continuous stream of liquid can be drawn with the expenditure of but 40 horse-power. That liquid air can be produced cheaply enough for commercial purposes is certain, since with the crude experimental apparatus in use, ten horse-power hours can produce about one gallon of liquid air. Mr. Tripler has in mind many improvements upon his apparatus which he will introduce in any new plant he may set up, and there is not the slightest doubt, that if the manufacture of liquid air be carried out on a large scale, its cost of production can be reduced to one-half.

Air has been previously liquefied, but the process was long and very expensive, and consisted in the successive employment of liquefied gases boiling at lower and lower points on the scale, the final cooling being affected by the rapid cooling of the product itself.

Within the last three or four years patents have been taken out by Dr. C. Linde in Germany, and Mr. W. Hampson in England. In both of these processes liquid air is produced without the aid of any intermediate refrigerating agents. Dr. Linde in 1895 succeeded in liquefying air with a pressure of 2,850 pounds only after a two hours' run. Mr. Hampson devised a piece of apparatus in 1896 in which he claims to have done much better. In both cases the quantities of the liquid air obtained were very small. In fact, it has been said that it is doubtful if either of these men ever saw a couple of gallons of this liquid air at any one time. Although both of these processes were great improvements over former methods, yet compared with Mr. Tripler's invention they cannot be considered as commercial.

The properties of liquid air and of its constituents as well as the effects of the exceedingly low temperatures upon the properties of materials have been partly investigated by Dewar, Wrobleosky, Olszewski, Pictet and Cailletet.

Liquid air is opalescent and has very much the appearance of a milky fluid. This is due to the suspended solid particles of carbonic acid gas which can be very easily filtered out. Its density is little less than that of water, being 0.93. It boils at the very low temperature of about — 310 deg. F., so that it is very difficult under ordinary conditions to prevent it from boiling. Prof. Dewar has devised a tube, shown in Fig. 3, to hold his liquid air, which was jacketed by a highly exhausted vacuum. He found that the liquid air placed in it would evaporate only one-tenth as fast as it would if placed in an unprotected vessel.

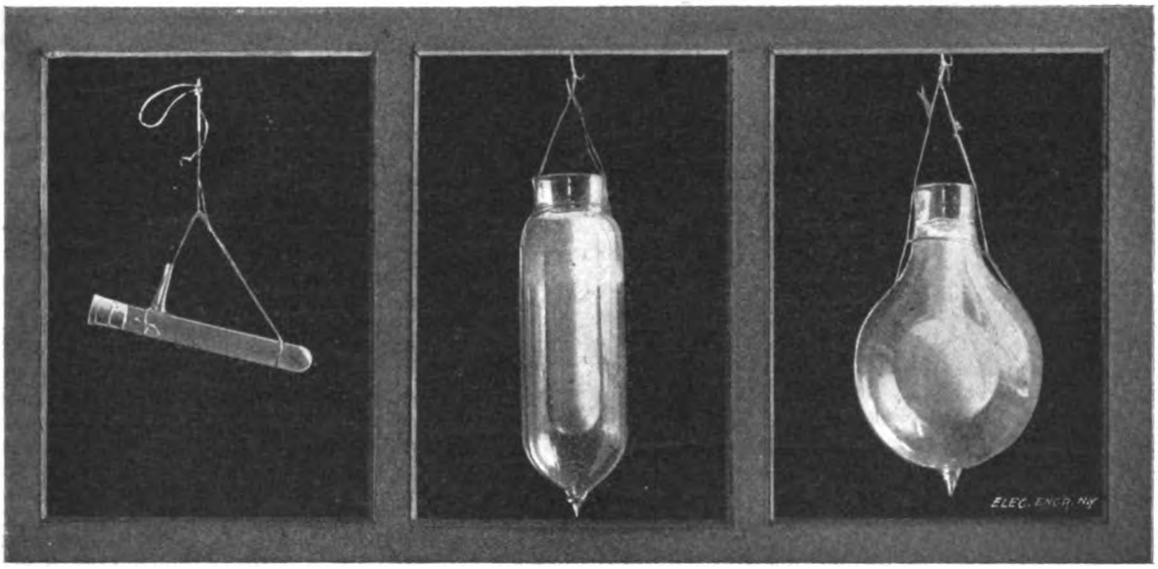


FIG. 1.—APPARATUS USED TO PROVE LIQUID OXYGEN MAGNETIC. FIG. 2.—PROF. PECKHAM'S VACUUM BULB. FIG. 3.—PROF. DEWAR'S VACUUM BULB.

Prof. Peckham has suggested the use of a different form, see Fig. 2, which has the advantage of being much easier and cheaper to manufacture. It also has the advantage that the surface from which the liquid evaporates is small and constant no matter to what level the liquid may be in the tube, whereas in Prof. Dewar's, the surface from which evaporation takes place is quite large when the bulb is not full.

The boiling point of liquid oxygen is — 299 deg. F., whereas liquid nitrogen boils at — 317 deg. F. When liquid air is allowed to stand, the nitrogen boils off faster than the oxygen, the result being that the air becomes continually richer in oxygen. Ordinarily air contains but 20 per cent. of oxygen, but by transferring the liquid air several times from one vessel into another and then upon filtering out the solid carbonic acid gas, a bluish liquid is obtained which is almost pure oxygen.

One of the most interesting and at the same time one of the most successful lectures given this year before the Brooklyn Institute of Arts and Sciences, was that by Prof. William C. Peckham on liquid air, at Adelphi College, Brooklyn, on Friday evening, March 25.

The experiments performed by Professor Peckham may be grouped under the following headings: 1. Excessive low temperature of liquid air and its utilization in freezing a number of substances having low freezing points. 2. Its great expansive power when enclosed. 3. Chemical action of the liquid oxygen upon different substances. 4. Effects of this very low temperature upon the properties of various materials.

1. Some liquid air was thrown upon a cake of ice. The ice was so warm compared with the air that it sizzled, the air assumed the spheroidal state and acted very much like drops of water on a red hot stove. A jet of steam in passing over a vessel containing some of the liquid air, was instantly frozen, and fell into a dish in the form of little hailstones. Supposing that the steam was only cooled down to the temperature of ice, it lost in an instant 1,290 deg. F. Some absolute alcohol was placed in a test tube and a string inserted, the whole being placed in the liquid air. In a short time the alcohol was frozen solid and was exhibited to the audience suspended by the string.

2. Its great expansive power was shown very strikingly by confining some of the liquid air in a closed tube and closing it up very tightly. In a short time the temperature of the room had caused so much of the air to expand that a great pressure was generated in the tube, which resulted in a sharp explosion and the blowing out of the stopper with a terrific force.

3. Liquid oxygen, although boiling at the low temperature of —299 deg. F., does not seem to lose its chemical properties as do a number of the active elements, prominently fluorine. An electric arc light carbon, heated red hot and inserted into the liquid burned brilliantly. Liquid oxygen has also the same chemical effects upon phosphorus and iron.

4. At very low temperatures a number of substances such as iron and tin become very brittle, breaking as easily as glass, whereas other materials, such as copper and aluminum do not change at all. The tensile strength of all materials increases as the temperature is lowered. At the temperature of —292 deg. F., iron has twice as great a strength as it has at ordinary temperatures. A wire that broke at 14½ pounds at ordinary temperature was cooled down and it was found that its tensile strength rose greatly, breaking only when the spring balance indicated a pull of 25 pounds.

Certain materials, such as ivory, when cooled down to this very low temperature, became phosphorescent when exposed for a short time to a strong light, as that from an ordinary arc lamp. This was tried with an ivory ball, and upon the room being darkened, it was found to be phosphorescent and had very much the appearance of a small artificial moon. An egg was found to exhibit the same phenomenon, though not to such a marked degree.

A tube containing liquid oxygen, having an outlet to allow for the free expansion of the liquid, was suspended by a silk thread, as shown in Fig. 1. As soon as the pole of a magnet was brought near it the tube was strongly attracted, proving that liquid oxygen is magnetic.

Dewar and Fleming found that the resistance of all the pure metals decreased greatly at low temperatures, and that the temperature co-efficient of resistance for all the pure metals, except platinum, increased as the temperature was lowered. The curves plotted tended to show that all the pure metals would become perfect conductors at absolute zero, or —273 deg. C. The fact that the change of resistance of platinum follows a straight line ratio, serves as a means whereby low temperatures can be measured merely by the change in the resistance of a coil of platinum at the different temperatures. The writer measured the resistance of a copper coil at ordinary temperature. The coil was then cooled down, though not to the temperature of the liquid air, as the supply of the latter was very nearly exhausted. He found that the resistance of the coil dropped from 1.8 ohms to about 0.6 ohms, showing a drop in resistance of about 70 per cent. Dewar and Fleming found that a coil of copper wire having a resistance of 17.5 ohms at 0 deg. C., fell to 1.65 ohms at —201 deg. C. If the temperature co-efficient for copper had remained constant along the whole range of temperature, it would have had a resistance of 3.43 ohms at this low temperature. The curves for alloys seem to show that the temperature co-efficient is approximately constant over very long ranges of temperature, the alloys having finite resistances at absolute zero.

The question whether liquid oxygen is a conductor or insulator seemed interesting. It was found, though very roughly, that liquid oxygen was a non-conductor of a specific resistance very much greater than that of distilled water.

The effect of low temperatures upon the magnetic properties of iron, was investigated by Dewar, who found that a magnet immersed in liquid air had its power increased about 50 per cent.

The practical use to which liquefied air may be put is of course very important, and will probably interest the public most, although it is hoped that the investigation of the effects of intense cold upon the properties of different materials may throw a good deal of light upon a number of scientific phenomena. The very low temperature of liquefied air, as well as its great latent power for the production of cold, renders it a very desirable product for purposes of refrigeration, and it is thought that this may prove, compared with present operative processes, a better and more economical method.

It has already been said that on account of the lower boiling point of nitrogen, liquid oxygen can be mechanically separated from the liquefied air. It is thought that the method for obtaining oxygen in this way from the liquid will compare very favorably in cost with the chemical methods now in use.

It is possible also, that the great expansibility of the air from the liquid to the gaseous form, producing great pressures when restricted in space, may be utilized as power to operate motors working by means of compressed air.

Manufacturing Aluminum and Its Sulphides.

AN interesting application of electrolysis to the manufacture of aluminum, sulphide of aluminum, etc., has recently been successfully caried out by D. A. Peniakoff, at Huy, in Belgium. The essential features of the process, according to the "London Electrical Review," are as follows: A single or double anhydrous aluminum salt, such as a fluoride or chloride, fused with the sulphide of an alkali or alkaline earth, together with a chloride or fluoride as a flux, yields a mixture containing aluminum sulphide, from which, in the same crucible, aluminum may be reduced, either by the action of an electric current, or by means of reducing gases (such as hydrocarbons, for example). The following formulæ present examples of the preparation of aluminum sulphide:

(1) $Al_2 F_6 + 3 Na_2 S = Al_2 S_3 + 6 Na F$.

(2) $Al_2 F_6, 6 Na F + 3 Na_2 S = Al_2 S_3 + 12 Na F$.

(3) $Al_2 Cl_6, 6 Na Cl + 3 Na_2 S = Al_2 S_3 + 12 Na Cl$.

When the bath is constituted according to the reactions (1) or (2), if aluminum be reduced from the fused mass, the supply of aluminum sulphide is kept up by additions of aluminum sulphate and carbon; aluminum fluoride and sodium sulphate are first formed, according to the equation $Al_2 3 SO_4 + 6 Na F = Al_2 F_6 + 3 Na_2 SO_4$, and the sodium sulphate is reduced to sulphide by the carbon, with subsequent production of aluminum sulphide, according to equations (1) and (2). It is stated that even where the sulphide of aluminum produced in the bath is subjected to electrolysis, the sulphide alone may undergo the electrolytic action, and not the fluoride, as the latter requires for its electrolytic decomposition a far greater electromotive force than that which suffices to bring about the decomposition of the sulphide of aluminum. Besides, where electrolysis is resorted to, the sulphur separated from the aluminum serves, for the most part, to reduce the alkaline sulphate to the condition of alkaline sulphide, thus adding its effect to the action of the carbon.

MR. GEORGE WESTINGHOUSE, JR., offers the entire electrical equipment as a gift to the proposed new Allegheny Observatory, comprising generators, motors, etc., of Westinghouse make.

CHICAGO LIGHTING.—The Comopolitan Construction Co. has been formed with a capitalization of $500,000, to build a $500,000 plant for the Cosmopolitan Electric Co., which claims to have laid already 75 miles of conduit for its work. The latter concern has a capital stock of $2,000,000. There is much curiosity as to the outcome of this scheme.

MAYOR VAN WYCK, of Greater New York, has vetoed the resolution to spend $35,000 on an electric light plant for the Recreation Pier at East Twenty-fourth street.

LITERATURE

PRACTICAL ELECTRICITY. By Prof. W. E. Ayrton. Volume I. London, 1896: Cassell & Co., Ltd. 643 pp.; 5 x 7 inches. Cloth. 247 Illustrations. Price, $3.50.

Prof. Ayrton's work, which appeared originally some ten years ago, was at once accorded a place among the standard treatises on the subject, and many a student has obtained his first inkling of the principles of the science from its pages. In more than one respect Prof. Ayrton's "Practical Electricity" differs from other works of the same general nature. Without desiring to disparage the good work of others, we think it may be fairly said that Prof. Ayrton has probably thrown more philosophy into his work than has any other similar writer, at least in the English language. By that we do not mean to say that the work is at all philosophical in the ordinary sense of the term; on the contrary, it is about as practical a work of its kind as could well be gotten together. In the elucidation of principles it is particularly strong, and the methods for bringing out the truths are exceedingly apt. The present volume which treats of current, pressure, resistance, energy, power and cells, has been completely re-written and is based on the international system of the electrical units. Both as a text book as well as an elementary laboratory manual the book stands without a rival.

ENGINEERING CHEMISTRY. By Thomas B. Stillman, Ph. D. Easton, Pa., 1897: Chemical Publishing Company. 523 pp.; 6 x 9 inches. 154 Illustrations. Cloth. Price, $4.50.

There is scarcely an industrial establishment of any kind which does not at one time or another require the analysis of material worked up or produced by the factory, not to mention many other tests which are desirable to obtain factory economy. Some handy work which will enable a fairly intelligent engineer to carry on an analysis, must be of the greatest value. Dr. Stillman has gotten together in the present work, a most comprehensive series of analyses, the complete list of which would alone occupy considerable space. We may, however, state broadly that we find therein full and complete direction for the determination of the amount and purity of metals, in most industrial salts employed, such as alum, etc.; lead, phosphoric acid, iron in ores, sulphur, carbon, etc. There is also an extensive treatment of coal and coke; analysis of water to determine the scale forming ingredients; composition of boiler scale; analysis of chimney gases; the manufacture of water gas and the calculation of heating power of various illuminating gases; practical photometry; the examination of the lubricating oils, of paints; pyrometry, etc.

We have selected but a few of the subjects treated of at random, but they will give a fair idea of the scope of this excellent work. Besides the complete direction for carrying out the analyses, all the apparatus required for that purpose is fully illustrated by the very clever engravings, so that those having even a limited knowledge of chemical analysis ought to be able to obtain results approximating closely to the truth The book is unquestionably one of the best of its kind which has yet come under our notice, and will be an excellent vade mecum for chemists, as containing the best of up-to-date methods.

INSTRUMENTS ET METHODES DE MESURES ELECTRIQUES INDUSTRIELLES (Instruments and Methods of Industrial Electrical Measurements). By H. Armagnat. Paris, 1898: Georges Carré et C. Naud. 586 pp., 5 x 8½ inches. 175 Illustrations. Flexible covers. Price, $2.40.

As chief of the bureau of electrical measurements of the Carpentier Laboratory, the author has had unusual facilities for acquiring the experience to fit him to undertake the work before us. He says very truly, that beginners lack most generally the knowledge of measuring instruments, their qualities, and particularly the limits of their employment. The book is divided into two parts, the first of which treats of the general principles embodied in measuring apparatus, the second part being devoted to the description of actual methods of measurement in general use, with full direction for carrying them out.

While the author has not entirely eschewed mathematics, a knowledge of them is essential to the complete understanding of the work, but even those little familiar with their application will find enough in it to make it valuable to them. The illustrations also will be found very helpful, representing as they do a good collection of standard measuring instruments in use at the present time.

ELEMENTARY MANUAL OF MAGNETISM AND ELECTRICITY. By Andrew Jamieson. Fourth edition. London, 1897: Charles Griffin & Co., Ltd. 297 pp.; 5 x 7 inches. Cloth. Price, $1.40.

This manual is too well known to require a detailed review at this late day. The present edition has been revised and brought fully up to date. For compactness and directness of application of the principles to practice, we know of no more valuable aid to the beginner. The illustrations are admirable and chosen with evident care. The book can be highly recommended in every way.

PATENTED TELEPHONY. Published by the American Electrical Engineering Association. Chicago, Ill., 1897. 5½ x 7½ inches. 102 pp.; 27 Illustrations. Cloth. Price, $1.50.

In these days of fierce telephonic competition, calling into existence many types of telephonic apparatus, not a few are interested in the ever present patent question; for although the sky of telephonic litigation appears serene at the present time, there is probably no telling when the storm may break forth again, and to be fore-warned is fore-armed.

The present volume presents a review of the patents pertaining to telephonic apparatus, and although in a small compass, gives the result of a considerable amount of research. It abstracts from the specification and claims of most of the so-called "controlling" patents still in existence, and is, one may say, a very good résumé of the present state of the telephonic art. All engaged in telephonic work will probably find much to interest them in its pages.

The "conclusions" given at the end of the volume will make interesting reading to many in the ranks of the "opposition" as well as those in the Bell camp.

GREELY'S SIGNAL SYSTEM FOR THE COAST. General Greely, Chief of the Signal Service of the army, is hastening the completion of plans for establishing a system of telegraphic communication along the coast from Portland to Jacksonville. Between New York and Savannah the Weather Bureaus maintain several sections of telegraph lines. These will be connected. It is proposed to erect at stated distances along the coast signal stations. They will be of uniform pattern, to cost about $2,000 each. Semaphores will be used to communicate with vessels at sea. To General Greely has been allotted $100,000 out of the emergency fund of $50,000,000, which will be used in perfecting the signal service.

CHICAGO POLICE TELEPHONES.—Every police station is soon to have a public telephone, so that citizens may call for help without having to rush around to discover a policeman. City Electrician Ellicott has also replaced the gravity batteries with storage batteries in the police and fire departments, effecting a saving of $5,800 a year.

ILLUMINATING PITTSBURG.—The Knights Templar Committee at Pittsburg, where the next triennial conclave is to be held, has closed a contract with the Sawyer-Man Co. (Westinghouse), for 30,000 lamps of 16 candle-power, with which to illuminate arches and buildings.

MR. C. H. BOOKOUT, who is a full-blooded Indian, has become station agent at Wilmore, Kan. He was once a section hand, but studied telegraphy.

CHICAGO TELEPHONE CO., in case of war, has proposed to notify all its 18,000 subscribers by telephone inside of twenty minutes.

Vol. XXV. NEW YORK, APRIL 14, 1898. No. 519.

Emasculating the Broad Patent on the Trolley.

THE full text is given in our Legal Notes this week of the decision in the U. S. Circuit Court of Appeals reversing the order given for an injunction under the broad Van Depoele patent, against the Union Railway Co. and the Walker Co. as manufacturing the underrunning trolley, alleged to infringe. This virtually ends the contention, for a time anyhow, and leaves open to the public the use of the trailing, freely mounted trolley arm pressing upward against the service conductor. The matter in various forms has had such diversified shape and fortune that even those interested in electric railway work have lost the run of it. If we recall the facts aright, the Van Depoele patents, always regarded as a valuable asset of the Thomson-Houston Company, were brought to bear against the Westinghouse Co., to exclude them from street railway work, and the decision of Judge Townsend, in 1895, sustaining one patent, was a decided victory for the General Electric Co., preceding, and probably helping to precipitate, the federation of the two concerns. The Walker Co. then involuntarily took up the gage of battle, and is to be credited with carrying through a difficult struggle to its present pronounced success. In what is known as the "Hoosick case" the lower court upheld Judge Townsend's decision, but the Circuit Court of Appeals, through Judge Wallace, decided the case in favor of the Walker Company, holding the patents invalid as to five of the claims, and thus practically reversed the Townsend decision.

The fight then reverted to two other claims. In February last, Judge Lacombe decided in favor of the patent on these two claims, but the Circuit Court of Appeals has just reversed the decision, and has practically held the entire patent void.

The decision, as in the Hoosick case, is that Van Depoele took out an earlier patent for substantially the same invention, although with narrower claims. That earlier patent is in force, and will probably remain in force for some years, but its claims are narrow and have been so construed by the same Circuit Court of Appeals in the "Elmira case." The data as to these points will be found in the decision itself, which would appear to leave the making and use of the underrunning trolley broadly open. It is not to be forgotten that these U. S. Circuit Court of Appeals' decisions are practically final in patent litigations. We think there can be little question as to the value to the art of the late Mr. Van Depoele's pioneer work, but such decisions, so far as they are operative, show once again that it is as dangerous to patent too much and too often as it is to patent too little or not at all. "Broad patents" once secured, are best let alone for what they are worth. The Walker Co. has had no small courage in making this uphill, dubious fight, and even should further struggles impend, is in a position to reap decided advantage from it. We print elsewhere the view taken of the situation by the General Electric Co.'s legal advisers.

General Electric Affairs.

PERSISTENT rumors, now believed to be well founded, have been afloat as to an early readjustment of the finances of the General Electric Company. It is certainly high time, for there is no question that it is a detriment to any line of industry to have its largest producer in prolonged non-dividend paying condition. At the present moment, dividends on preferred General Electric stock have accumulated up to 35 per cent., or just five years at 7 per cent., and that on $4,250,000 preferred is about $1,500,000. The $30,460,000 common stock has got nothing in a like period. The impairment of capital, avowed, is about $13,000,000 and no dividends can be paid until that is repaired in some way. The company has an enormous productive capacity and is as busy as it can be. Indeed, one result of the huge capitalization of the company is that it has engaged in many lines it might well let alone, in order to secure a huge turnover, justifying that capital's existence, running up with the bonds, over $40,000,000.

It is said that the new plan will go through, and as now understood it is as follows: The capital impairment is to be made good by reducing the thirty millions of common stock 50 per cent., making the amount of that class of shares outstanding some $15,000,000. The claims of the preferred stockholders to unpaid dividends are to be settled by turning over to them some $2,000,000 of 5 per cent. debenture bonds of the company now in its treasury. This, it is said, would be acceptable to all interests, and, upon the basis of the current earnings, the company would be able to pay 4 per cent. annual dividends on the reduced amount of common stock. This plan will probably be submitted at the company's annual meeting in May if present hopes are realized.

Prof. Fleming's Use of the Heavisidian System of Nomenclature.

IN his recent lecture on "Magnetism and Diamagnetism," before the Royal Institution, Prof. Fleming made use of the rational system of units proposed by Mr. Oliver Heaviside, which once again calls to mind the necessity of a universal adoption of units and definitions. It will no doubt take some time before electrical engineers are in a position to use the terms fluxivity, retentivity, magnetivity, coercivity, and gaussivity, etc., correctly, for even Prof. Fleming inadvertently made use of the term "magnetic force" for "gaussivity" several times during the course of his lecture. He also urges great objections to the use of the term "force" in connection with any other idea than that of change in momentum of material substances. Instead of employing the term "magnetomotive force," he believes it would be better to express the same notion by speaking of it as the "gaussage" of the magnetic circuit. The magnetomotive intensity or gaussage per linear centimetre might be called the "gaussivity" acting on the circuit at the specified place. The principal magnetic facts could then be expressed by the simple statement that gaussage (measured in ampere turns) produces magnetic flux (measured in webers) in magnetic circuits. The intensity of this cause or effect is described by stating that the

gaussivity (in ampere turns per linear centimetre) produces in the circuit a certain "flux density" or flux per square centimetre. The "reluctance" of the magnetic circuit is that quality of it in virtue of which gaussage is required to produce "change in magnetic flux." The "reluctivity" of a circuit at any place is the reluctance of a cubic centimetre of it at that place and under the assigned conditions. The "retentivity" is that magnetic quality of the material in virtue of which magnetic flux persists after gaussage is withdrawn. The "coercivity" of the material is that magnetic quality of the material in virtue of which a reversed gaussage is required to annul or wipe out magnetic flux. This nomenclature certainly appears to be very reasonable and acceptable, and one which should commend itself to every teacher and student of electricity and magnetism. If it does meet with the approval of the scientists of this country, we should advise its speedy introduction into our colleges and text books, following the splendid example set by Prof. Fleming. If, on the other hand, the system has inherent faults which may become apparent, and might confuse rather than simplify matters, the proposed system should at once be made the subject of a discussion having for its final object the introduction of a system of nomenclature which will be acceptable to all.

The Electrical Exposition and War.

WE publish on another page the latest list of participants in the approaching Electrical Exhibition, and surprisingly large as it is, we understand that many other names are being added. The grim uncertainties of war might discourage some exhibitors if it were not known as an actual matter of fact and experience that at such times places of amusement are fuller than ever, it being difficult for people to stay at home in their houses while big events are taking place and while vital news may come at any moment. Moreover, it may be surmised that an art of which so many branches touch upon the implements of warfare will have numerous things to demonstrate of peculiar interest and importance at such a season. The exhibition management has, to our knowledge, been pursuing a highly liberal policy in the provision of special features, some of which have already been noted in our columns; and we are certain that when the full result is seen, both the public and the exhibitors will be not only pleased, but gratified and delighted.

After all, in these modern days, "peace is long" and war is short, and in the realms of peace electricity has a future of unbounded prosperity and magnitude. But there is still a tremendous amount of work to be done in educating the general public up to the approval and purchase of the novel electrical appliances as they come forward; and these exhibitions are in some respects unequaled as factors for that purpose. The electrical press is steadily doing a great work in all directions in behalf of the interests it represents, and its public spirit has been shown in the zeal with which it welcomes every new agency that can aid it in the work. But people who are loathe to read technical literature can be quickly reached through the eye and ear, and an impression is thus made which lasts and becomes fruitful.

Electricians in the Navy.

IT is announced that an executive order of the President has established the ratings of chief electrician, electrician first class, and electrician second class, to be taken from civil life for service in the navy. They will be required to pass a physical examination and professional examination at the Navy Yard, New York, before a board that will be established. The pay will be $50, $40 and $35 a month, with rations. This will be interesting news to many who have watched the gradual introduction of electrical apparatus into the U. S. Navy for a large variety of uses. In the early days, the care of electrical work was entrusted to one of the junior officers with tastes for electricity, but now there is enough electrical apparatus on board any up-to-date man-of-war to keep two or three competent electricians busy all the time. The salaries named are not large, and certainly will not command the best talent on the market, but the probability is that such berths will offer inducements to many well informed young men willing to serve their country afloat.

The Telephone as a Life Saver.

IN view of the fact that there are excellent telephones for divers' helmets, it is hard to explain or excuse the recent death of a diver at Key West. It appears that Chief Gunner's Mate Johnson, of the gunboat Newport, was asphyxiated last week while in a diving suit examining the ship's bottom. It was the usual quarterly examination. The air pumps were kept working regularly. The diver gave no signal to be hauled up. At last the tenders became alarmed and pulled him up. He was dead in his suit. The cause of the asphyxiation is not yet clear, but it is supposed that the air pipe fouled at the bottom, and was squeezed so as to cut off the supply of air. We may be wrong, but the mere tinkle of a bell from below, or the cry of distress to anyone listening at the telephone would be sufficient to prevent such deaths, and the apparatus costs so little!

General Electric View of the Trolley Decision.

AS we go to press, we are in receipt of the following from the General Electric Co., in regard to the trolley decision of the U. S. Circuit Court of Appeals :—

"The decision rendered by the Circuit Court of Appeals in the suit brought by the Thomson-Houston Company against the Union Railway Company under Van Depoele under-running patent No. 495,443, is not final but came up under a motion for a preliminary injunction. It is understood that testimony is now being taken, and that the case will be pushed to final hearing in the immediate future. The decision of the Circuit Court of Appeals was to the effect that an injunction should not be granted pending the final hearing.

"This is but one of a number of trolley patents under which the Tomson-Houston Company is suing various manufacturers or users of the infringing trolleys. Among the other suits is one under Van Depoele patent No. 424,381, the special feature of which is the use of a tension spring occupying a horizontal position and pressing the trolley arm upward. This construction is universally used as it permits the trolley arm to be brought down close to the roof of the car. Another patent under which suit is pending is No. 502,243, which relates to the use of oppositely acting tension springs, of which one set "rests" while the other is in use.

"Another patent of Van Depoele under which suit is pending is No. 495,383, which covers the reversible trolley, that is to say, one which may swing freely around its vertical axis so as to trail in either direction.

"Two other cases will be argued during the present week, one on the Anderson patent No. 412,155, and the other under the Baker patent No. 437,961. These patents relate respectively to means for conducting current from the trolley wheel to the harp, and to the use of buffer-springs for checking the motion from the trolley arm when it escapes from the wire.

"All the principal manufacturers are under injunction with reference to the Van Depoele switch patent No. 424,695, this patent having been sustained at final hearing.

"In view of these several patents relating to the essential features of the under-running trolley, the effect of the decision of the Circuit Court of Appeals does not throw the under-running trolley open to the public; the switch patent alone practically controls the situation, as it is impracticable to run a road of any considerable size without the under-running switches."

Considerations Governing the Design of the Crocker-Wheeler Slow Speed Motors.—III.

BY GANO S. DUNN, CHIEF ENGINEER.

THE details of these motors have received equally careful attention The brush-holding "rigging" is shown in Fig. 7. The design adopted is particularly desirable where the number of poles is large. Two carrying rings are used, which, while mechanically supporting the brush rods, connect them electrically, the rods being fastened to them. One of these rings holds all the positive, and the other all the negative studs. The rings are insulated from each other, but are mechanically one, and shifting of brushes is obtained by moving them just the same as a purely mechanical holder would be moved. The rings therefore do away with the insulating of the brush rods and the connecting of the alternate studs by cables. On account of the room saved by this arrangement, the carrying rings can be placed next to

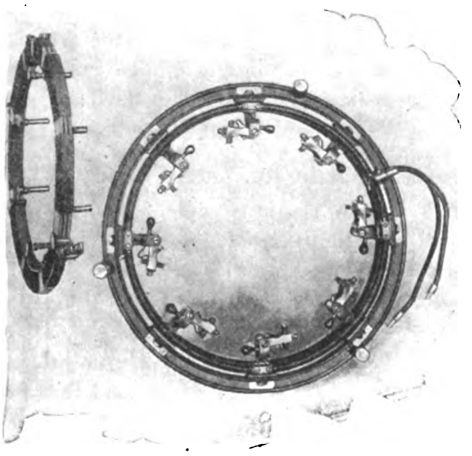

FIG. 7.—SIZES 5-100 TO ½-100 C. W. MOTOR BRUSH RIGGINGS.

the armature, permitting the studs to point outward and over the commutator, which enables a brush holder to be withdrawn for cleaning or adjustment even while the motor is running. The keeping of the carrying ring close to the frame, not only leaves the commutator clear and easy of access, but greatly enhances the pleasing appearance of the motor.

The commutators, being for machines of many poles, are of large diameter and short, and have a great many bars. The connections from the armature are made to tails riveted to each bar and these are long enough to prevent the melting of the solder holding the wires in place in case of serious overheating from the action of the brushes or other causes. The armature has an extended sleeve upon which the commutator is keyed, so the whole acts as one part.

Before passing to the description of methods of control adopted, the writer would point out a characteristic of low-speed motors which in certain cases gives them an important advantage over others. Their moment of inertia is low and permits starting from rest in a minimum of time and with a minimum of current. The energy necessary to bring a rotating body to a given speed is, in the case of an armature, approximately proportional to its weight, its diameter, and the square of its speed. If we compare a size 2 standard armature, giving 2 h. p. at 1,000 r. p. m., with a size 2-100 armature, giving 2 h. p. at 100 r. p. m., we shall find that the product of the moment of inertia by one-half the square of the angular velocity of the former is 900 foot-pounds, while for the latter it is 280 foot-pounds, or nearly four to one, in spite of the fact that the high-speed armature weighs only one-fifth as much as the other. This means 3.2 times as much work must be expended upon the armature of the high-speed motor to bring it from rest to normal speed as is necessary for the low-speed one; where the duty the motors have to perform requires quick and frequent starting and stopping, as with elevators and cranes, the driving of roll tables in iron mills and in printing press work during the time of "making ready,"

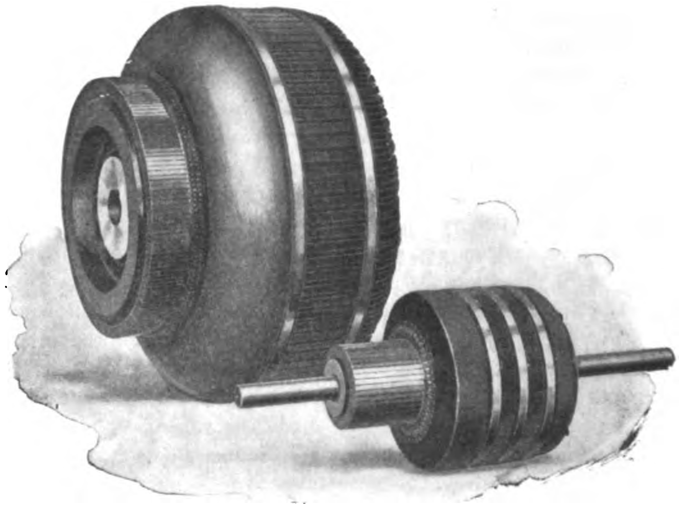

FIG. 8. COMPARISON OF ARMATURES OF MOTORS.
(Size 2-100, 8 pole, 2 h. p. at 100 rev., with size 2, bi-polar, 2 h. p. at 1,000 rev.)

this difference is very noticeable and plays an important part in the economy of the plant. Fig. 8 illustrates graphically the comparative sizes of these armatures.

REGULATION AND CONTROL.

The regulation, or constancy of speed, under variations of load of the shunt wound slow motors, depends greatly upon the speed for which they are wound, since it is largely dependent upon armature resistance, which, as we have seen, varies with the square of the speed. For the speeds at which

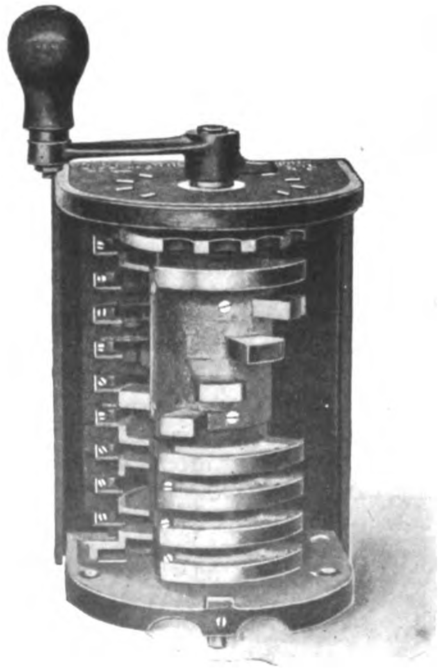

FIG. 9. 25 AMPERE COMMUTER.

the motors usually run, which is in the neighborhood of two hundred revolutions, the regulation is much less perfect than for high speed motors. A 5 h. p. standard motor at 950 revolutions will slow down 4 per cent. when full load is thrown upon it; but a size 2-100 giving 4 horse power at 200 revolutions per minute will reduce its speed about 15 per cent. under the same conditions. This imperfect regulation does not make itself felt,

however, for in most of the work of these motors there is a large element of constant load which makes any variation only a small portion of the total, and is, consequently, accompanied by a variation in speed, which is only a small portion of the full load speed variation.

In these motors there is a demand for a control of speed over a considerable range, which is met by designing them with distant sparking limits, so that the field may be much weakened and the speed correspondingly increased without trouble at the commutator. In shunt machines the field is controlled by an ordinary rheostat, or is wound in multiple sections, whose circuits are opened successively. Series wound motors have their speed controlled by the short circuiting of various portions of the field in certain order.

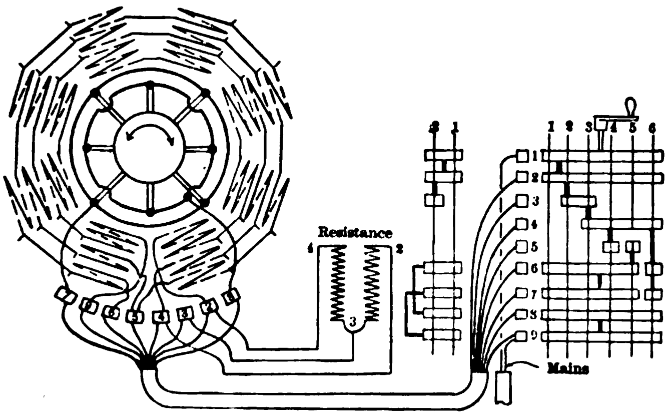

FIG. 10.—REVERSING COMPOUND-WOUND DIRECT MOTOR WITH COMMUTATOR.

Compound wound motors, the kind sometimes used for printing presses, have a constantly excited shunt field, supplemented by a series field in two sections, the whole controlled by a controller of special design; or they may have an unvaried series coil, with a shunt coil whose strength is changed by a field regulator in the well-known way.

To increase a motor's speed by weakening its field is so easily accomplished that it is not appreciated how severe are the conditions it imposes, conditions which, were they not met by special design, would be impossible for the motor to withstand, and with which it is difficult for even special design to cope.

It is well known that sparking at the commutator depends largely upon the character of the magnetic fringe around the edges of the pole shoes, and that it is also dependent upon the amount of current flowing in the armature. The weakening of the motor field, which compels the armature to increase its speed, weakens simultaneously the magnetic fringe which is relied upon to perform the operation of commutation, or the proper reversal of current in each little section of the armature when passing the region of the brush. This reversal, no longer properly accomplished, causes sparking, which sooner or later destroys the commutator.

But the weakening of the fringe is not all. The increase of speed causes the motor to do more work or develop a greater horse power. This draws proportionally more current from the line, putting upon the armature, already struggling with the burden of commutating in a weakened fringe, the additional burden of an increase of load. It is needless to point out how the 50 per cent. increase of armature current causes a more than doubled heating of the conductors.

From the foregoing it might be inferred that a motor rated for the maximum speed and output would solve the problem, but, unfortunately, even more than this is required, for such a motor would not be capable of reaching the lower speeds, as its field magnets would be saturated.

Having described the difficulties that apparently simple speed regulation involves, we will explain how they have been met in these motors, all of which are capable of an increase of 50 per cent. above normal, and a decrease of 10 per cent. below normal speed.

The magnetic fluxes employed for normal speed are much in excess of the fluxes required; therefore, when the weakening has taken place, there still remains a proper strength for commutation. This excess of magnetic flux obviously involves a corresponding increase in the size, weight, and cost of the magnetic circuits of the frame and armature. The increase of the load accompanying the increase of speed, which tests most severely the sparking limits, is provided for by proportioning the commutator and brushes so that they will appropriate more than their usual share of the labor of commutation, and prevent the sparking that would occur as a result of the overloaded armature's reaction upon the weakened fringe. This involves a large commutator with small differences of potential between the bars and large allowance of brush area, subdivided to obtain as much commutating edge as possible.

The speeds below normal are obtained by pushing to full saturation the iron worked normally, for reasons of efficiency, to only a moderate portion of what it is capable, and by utilizing the resistance of the series coils when they are employed, to cause a slight reduction of voltage. This forcing requires considerable field energy, but the exciting coils are designed not to be overheated by it, and the only drawback is a slight reduction in efficiency at the very lowest speeds.

The speed variations we have just described are accomplished without the introduction of external resistance into the armature circuit, and if it should be desired, they may be accomplished without the use of a regulator in the field circuit; but as a rule, this is the most convenient means of control, and, since it operates on the extremely small field current, the losses it involves are insignificant. Throughout the speed range we have been describing, the motor's regulation is not sensibly impaired. At whatever speed the regulator calls for, the motor will run constantly within the limits set for it.

Although a range from 10 per cent. under to 50 per cent. over normal speed, or 60 per cent. of normal in all, is great enough to meet almost all conditions, additional range may be had at the lower limit by the employment of resistance in series with the armature. For many classes of work the loss of constancy of speed which this involves is of no importance, since the load does not appreciably vary, and, under these circumstances, it is possible therefore to increase the range of speed control from 50 per cent. above to 50 per cent. and even 75 per cent. below normal.

These motors may be connected as plain, shunt, series or compound. The great objection to the series winding is that unless the current which a motor will take when running a given machine is accurately known, and the motor wound for that current, it will not run at the right speed when driving the machine, because its field strength and drop in voltage in the field coils will not be as calculated. Another objection to the series winding is that if the load fluctuates the speed will also vary widely.

The advantages of the shunt winding are: Constant or very nearly constant speed under all variations of load, and simplicity of control, which is effected by means of a regulator in the field circuit which wastes very little energy. The shunt motor is started and reversed by means of a controller and small resistance, which is entirely cut out of the armature circuit when the motor attains normal speed.

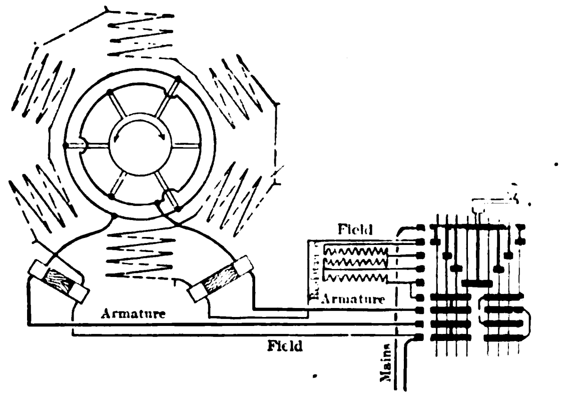

FIG. 11.—REVERSING SHUNT-WOUND DIRECT MOTOR WITH CYLINDER REVERSER.

The chief advantage of the compound winding is seen when the motor is under variable or "lumpy" load. The series coil of the field winding gives added field strength with increase of load, and, besides, by increasing the counter electromotive force, reduces the momentary excessive rush of current that would

otherwise flow, and which might cause dimness of nearby lights, or drop in speed of other motors. The shunt coil makes the speed less dependent upon the work of the armature than in the series motor. As explained above, the series motor varies widely in speed with the current. With the compound motor the power may vary within wide limits without a marked effect upon the speed.

CONTROLLERS.

Two kinds of controllers have been designed for these slow motors; the ordinary cylinder reverser, giving as many speeds backward as forward, operating through a resistance having one

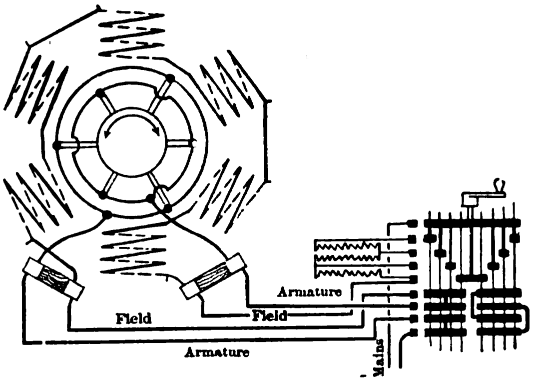

FIG. 12.—REVERSING SERIES-WOUND DIRECT MOTOR WITH CYLINDER REVERSER.

section for each speed, and regulating the speed of the motor by cutting down the voltage supplied by the line in the usual manner.

This cylinder reverser with a small resistance serves as a reversing starter for a compound motor, which has an unvaried series coil, but which has a shunt coil, that is weakened or strengthened by means of a field regulator. This method of controlling the speed of the compound motor by varying the strength of the shunt coil is so simple and well understood that we deem further explanation of it unnecessary.

The other kind of controller is what is termed a "commuter," specially designed for use with a compound motor, used principally for printing press work, but applicable to other work as well. It varies the speed of the motor after it has once started it, by adjusting the field strength by changes in the connections of the various series field coils. In this commuter, by a system of closed circuits through the field windings, parts of which it

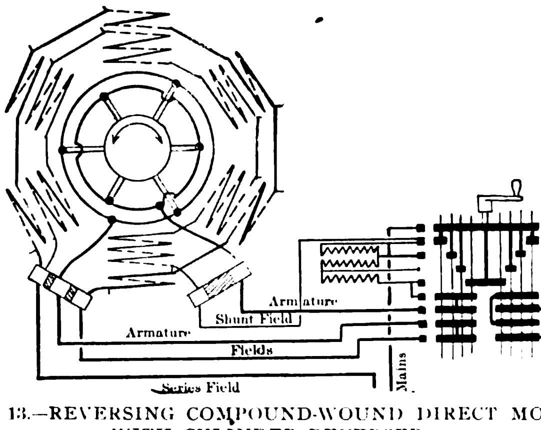

FIG. 13.—REVERSING COMPOUND-WOUND DIRECT MOTOR WITH CYLINDER REVERSER.

short circuits in proper order, arcs are avoided at all points except those actually engaged in opening the circuit to stop the motor, and these points, in addition to being made as durable and heavy as possible, are renewable, permitting the substitution of new ones when they have finally become too burned to be of service. In order to distribute the duty at stopping, the circuit is broken simultaneously at eight points, so that the arc is minimized and distributed. Fig. 9 shows the general appearance of a 25 ampere commuter, and Fig. 10 shows diagrammatically the connections, while Figs. 11, 12 and 13 show the connections for the cylinder reverser.

The Regulation and Protection of the Electric Motor.[1]—I.

BY HARRY H. CUTLER.

ELECTRIC transmission of power is fast becoming recognized as capable of almost universal application to all kinds of machinery. Scarcely a meeting of manufacturers, trade associations, or engineering societies takes place where something of a favorable nature is not said about this rapidly growing and important industry. It can be truthfully stated, however, that the public is only just beginning to recognize the adaptability of the electric motor, and that an enormous demand awaits it in the near future.

We now see motors not only fast displacing belts and shafting, but also operating many kinds of machine tools, traveling cranes, hoists and elevators, pumps, ventilating fans, printing presses, mining machinery, dredges, street cars, railways, vessels, air ships, implements of war, telescopes and scientific apparatus, and in fact almost every conceivable application of power.

Now there is one peculiar feature which comes up with each and every motor that is installed, namely, that a connecting link between the motor and what it is to drive must be provided which shall be adapted to the peculiar kind of work to be performed. This connecting link is the rheostat or controller, and the rapidly growing demand for these devices has given rise to what could almost be called the profession of rheostat engineering. By means of the rheostat or controller the motor is started and stopped, its direction of rotation is determined upon, and the speed at which it shall rotate is varied at will.

The same motor which drives a pump would drive a fan, a printing press, or a line of shafting as well, but the proper type of rheostat to use for these various applications of power would be vastly different in each case. Generally speaking there are but three kinds of direct current motors, the series, shunt and compound wound, and the best suited of these three types of motors is selected to do the work. The types of rheostats for controlling these motors, however, are so numerous that only a few can be mentioned in this paper.

By far the largest number of stationary motors in use to-day are direct current, plain shunt wound, non-reversing, and run at a constant speed. These motors are usually provided with motor starting rheostats, whose resistance is in circuit only during the few seconds consumed in starting the motor. Simple as these rheostats are, great care should be taken in selecting the size and style best suited for the work.

A motor that is started and stopped but two or three times a day can be satisfactorily handled with a starting rheostat that would frequently be almost useless for starting and stopping a motor two or three times a minute. A rheostat arranged to start a motor under full load to the best advantage will not start a motor equally as well at 100 per cent. overload. A rheostat satisfactory to the Fire Underwriters of Chicago is not necessarily adaptable to the New York authorities, and would be looked upon as unnecessary extravagance by the country trade. It is important then, even in the very simplest cases, that the character of the work should influence the selection of the proper starter or rheostat, and when it comes to applying a motor to almost any other use than that of driving belts and shafting, this question becomes of still greater importance. Most stationary motors are operated at constant speed, but consumers of power are finding out that the speed of a motor can easily be regulated at will and are calling for appliances which will accomplish this.

I can almost say that there is but one way by which the speed of a motor, of direct current, can be changed, and that is by changing the voltage across some of its parts or windings. There are a great many ways to accomplish this. The simplest, but unfortunately the most unsatisfactory way of reducing the speed of the motor, is to reduce the voltage across the armature by inserting external resistance in series with it. This method is uneconomical on account of the current absorbed by the rheostat, and also destroys the self-regulating property of the motor. The speed of a shunt wound motor varies approximately with the voltage across the armature or brushes; with external resistance in series with the armature, the speed will vary to a much greater extent for the following reasons: When the load on the motor is increased, the current, C, must increase.

[1]Read before the Chicago Electrical Association, April 1, 1898.

This increase of current can only occur by a decrease in speed which lowers the counter electromotive force of the armature, thereby permitting more current to flow. But the current, of course, has also increased in the rheostat, while the resistance, R, of the rheostat has, unlike the armature resistance, remained the same, hence, since $C = \frac{E}{R}$ we see that the electromotive force, E, across the rheostat, must be increased in the same way, in order to allow more current to flow. This increase can be derived only by slowing down the armature, and reducing its counter electromotive force. A very slight increase in the load when external resistance is in series with the armature will then often actually stop the motor entirely. Such cases as this have been so frequently causes of complaint from customers, that It would appear that the effect of external resistance in series with the armature is not at all well understood by either users, owners or salesmen of electric motors in general. The prevailing opinion seems to be that a speed regulator of the above type can be set so that the motor will run at a certain speed, independent of the load. In proof of this assertion, many orders can be shown from some of the largest manufacturers of motors in the country, calling for a certain number of steps in the regulator to give a corresponding number of fixed speeds for the motor.

Another method of changing the voltage across the armature is to operate the motor on a three-wire system, and connect the armature across the outside wires for high speed, and between the neutral and one of the outside wires for low speed. This method wastes no current, and causes the motor to assume a definite speed independent of the load.

Still another method, which is ideal so far as the motor regulation is concerned, is to connect the armature across a variable number of storage batteries, thus obtaining any desirable speed over wide ranges. Another method consists in so winding the armature that the coils may be changed from parallel to series, which can be accomplished in several ways.

Altering the voltage across the field of a motor also affects its speed, but in exactly the opposite way from that caused by changing the voltage across the armature. To increase the speed of a motor we can decrease the strength of its field, and there are many ways of doing this. The simplest and one of the best is the insertion of external resistance into the shunt field circuit. This method is not only very simple and inexpensive, but unlike the armature regulation through resistance, it wastes comparatively nothing in heat and allows the motor to assume the desired speed and maintain that speed independent of the load.

Motors are to be had of nearly all the large builders which will operate satisfactorily with a field variation of 50 per cent. in actual ampere turns. The same result is frequently obtained by using a compound wound motor, winding the series fields in separate sections and cutting out these sections one by one by means of a special switch. At least one manufacturer goes so far as to use so many of these field sections that their resistance is sufficient to prevent more than the proper amount of current from flowing, on closing the circuit, without using any external resistance whatever. The series windings are then cut out one by one as the armature revolves. A very powerful starting torque and a wide range of speed is thus obtained. This method, however, will not regulate the speed independent of the load, as the field strength cannot be kept constant. It is applicable, therefore, chiefly to cases where an attendant is constantly on hand, as in the case of elevators, cranes, and hoists.

One more method of varying the field strength consists in throwing the winding of the field cores into series connection for high speed, and series multiple for slow speed.

Motors are sometimes regulated by means of using a separate generator for each motor, and varying the voltage of the generator by means of its field rheostat. This method is known as the Leonard system, and gives perfect regulation over a wide range.

We have now before us a long list of methods from which to choose the system of regulation best adapted for the work at hand. One of the simplest and best is that frequently used for regulating motors driving fans and blowers, by means of so-called compound speed regulators. No large office or school building is now considered up to date which is not provided with artificial ventilation, which can be regulated at will.

The motors which drive the fans are so belted or geared to the fan that when the fan is operating at the average speed desired no external resistance of any kind is in circuit. To reduce the speed, the rheostat lever is moved to the left and resistance is cut into the armature circuit, and to increase the speed the lever is moved to the right and external resistance cut into the shunt field circuit.

To select the proper sized motor and to determine upon the proper speed to run the fan, requires an accurate knowledge of and experience with fans, air ducts, and the laws of moving air. This is another subject which has not been reduced to a science by fan builders. Some builders always use a series wound motor for driving fans, and others have adopted the shunt wound motor. When it is not necessary to vary the speed of a fan, the series motor is probably preferable as being simpler, but for driving large fans where speed regulation is always desirable, the use of a plain shunt wound motor and a compound wound regulator appears to be the best practice.

In proportioning the resistance for a fan regulating rheostat it must be borne in mind that the power required varies directly as the third power of the speed, and not directly as the speed as in driving shafting and machine tools. A regulating rheostat for a fan is therefore designed on entirely different lines, even the contacts and mechanism are different, because a fan is never started and stopped at frequent intervals during the day, and a cheap button front will do the work satisfactorily.

Diametrically opposed to the fan regulator is the electric elevator controller. This work calls for continually starting and stopping several times a minute, all day long. Heavy, renewable contacts are absolutely necessary, as well as a special type of motor, and problems of entirely different character are to be met with. It is not practical to build an elevator controller all ready to fasten to the wall, with a string hitched to it for the operator to pull. Such devices are on the market in abundance, but should be regarded as a source of great danger.

An elevator controller to be safe should be embodied into and form a distinct part of the elevator mechanism and should be attached to the elevator mechanism by the elevator manufacturer, and not by the motor manufacturer or their selling agents.

There are a great many good methods of operating electrical elevators on the market. Among these methods in most common use is the system which uses a compound wound motor and compound regulation. The motor is started through external resistance, which can consist of a rheostat or the windings of the series coils themselves. This resistance is then cut out in several steps under control of some kind of a governor; the series field coils are then cut out and finally the shunt field is weakened by the insertion of external resistance. The operation of electric elevators brings up the problem of: How to reverse an electric motor. To accomplish this it is only necessary to change the relative direction of the current in either field or armature circuits. The moment we do this, however, new trouble arises. Means must be provided to prevent the possibility of reversing the direction of the current without either first stopping the motor or at least inserting external resistance into the armature circuit. Means must also be provided to prevent excessive sparking or burning at the switches as well as undue strain on the insulation of the motor.

In order to reverse a motor the field and armature have to be controlled by independent circuits. Whenever a circuit is suddenly opened that contains coils of wire wrapped around a mass of iron, a secondary or induced current is formed, which has a potential many times higher than that of the primary current. This current not only burns the switches, but is sure to puncture the insulation of the motor, sooner or later, unless means are taken to prevent it. Many designs of elevator controllers and rheostats on the market try to overcome sparking by opening the circuit with a snap switch, but electricity cannot be fooled in any such a simple mechanical manner as this. The flash and consequent strain on the insulation of the motor is only increased the more, and all that is gained is that the switch does not burn up so quickly. This is no dream, but it is an actual fact that the market is flooded with rat trap devices which claim to eliminate sparking by means of snap switches. A snap switch is well enough for use in a lighting circuit, but when used in connection with a reversible motor it is a constant menace to the safety of its insulation. Everyone knows, who has handled a motor, that if the double pole knife switch is pulled even when the motor is heavily loaded, a destructive spark is never obtained. The reason for this is that the armature and

shunt fields are not separated, and consequently no induced current is formed in either and no strain whatever on the insulation occurs. The motor becomes a generator, energizing its own field and gradually slows down and loses its magnetism. A similar condition of affairs can be obtained on a reversible motor. Before opening either the field or armature circuits, both sides of the line should be opened simultaneously, which of course will cause no sparking as just pointed out. External resistance should then be inserted into the armature circuit, and finally the armature connections should be reversed, leaving the shunt field circuit at all times closed upon the armature. No destructive sparking or strain upon the insulation of the motor will then occur, the supply of current is absolutely cut off from the motor, and the short circuiting of the armature through the resistance of the rheostat occurring while the field is at full strength acts as a dynamic brake, and assists to stop the motor. This method of braking a motor is easily worked out, so that the ordinary mechanical brake never sets until the motor has stopped or nearly so.

MUNICIPAL AFFAIRS

Municipal Electric Lighting.[1]—VIII.

BY PROF. JOHN R. COMMONS.

THE following table gives the comparative charges for commercial lights under public and private ownership :

TABLE X.

COMMERCIAL RATES FOR INCANDESCENT LAMPS—16 CANDLE POWER.

Municipal Plants.

	Per Month.	Lamp Hour.	Per Kw. Hr.
Braintree, Mass.		6/10c.	
Chicopee, "			11.66c.
Hingham, "			20c. yearly. 25c. summer.
Hull, "	60c.	1c. amp. hour.	
Marblehead, "		½c. y'r'ly 1c. summer.	
Middlebor'gh, "		1c.	
N. Attlebor'gh, "		¾c.	
Reading, "		¾c. 1¼c. amp. hr.	15c.
Wakefield, "	90c.	6/10c. amp. hr.	
Jamestown, N. Y.	67½ c. all night; 40c. to 10 P.M.		8c. dwellings. 10½ factories.
Lansing, Mich.	75c.		12c.
Johnson, Vt.		1/3c.	
Griffin, Ga.			12c.
Logansport, Ind.			7c.
Webster City, Ia.	(av.) 25c.		10c.
Lisbon, Ia.	40c.	½c.	
St. Charles, Ill.	50c.		15c.
Benton, Ill.	50c.		
Harrington, Kas.	75c.		
Tecumseh, Neb.	$1.25 (1st 2) 50c. (above 4)		
Savannah, Mo.	50c.		15c.
Fulda, Minn.	50c.		
Salisbury, Mo.	10 P.M. 60c; 12 P.M. 80c	1c.	20c.
Alexandria, Minn.	65c.		15c.
Waseca, Minn.			15c.
Laverne, Minn.			10c.
Wells, Minn.	50c.		10c.
Litchfield, Minn.	40c.	2/3c.	
St. Peters, Minn.	9 P.M. 50c.; 12 P.M. 65c		12½c.
Rochester, Minn.		½c.	
Marshall, Minn.		6/10c.	
Coldwater, Mich.		6/10c.	11c.
Evart, Mich.	25c.		
Hamilton, N. Y.		1¼c.	
Westfield, N. Y.	50c.	½c.	
Madison, N. J.			10c.
Hamilton, Ohio	60c.		8c.
Jackson, Ohio	60c.		10c.
Willoughby, Ohio.	(Stores) 25c.		8c.
DeGraff, Ohio	25c.-40c.	6/10c.	
Galion, Ohio	70c. to 10 lamps; 65c. to 16		10c.
Quakertown, Pa.			12c.
Schuylkill Ha'en, Pa.	25c.-65c.		
Sharpsburg, Pa.			8c.
Wytheville, Va.	25c-50c-75c all night		
Salem, Va.	40c.-65c.		20c.
Rice Lake, Wis.	50c.		20c.

Private Plants.

	Per Month.	Lamp Hour.	Per Kw. Hr.
Abington, Mass.		9/10c.	20c.
Adams, "	6 nights. Per wk. $1.00.	1c. amp. hr.	20c.
Amesbury, "	90c.		
Amherst, "			20c.
Andover, "			24c.
Athol, "			20c.
Attleborough, Mass.	90c.		20c.
Beverly, "	1.16 2/3 for 7 nights. 1.00 for 6 nights.		20c.
Block Plant, "			16 2/3c.
Blue Hill, "	$30 pr. yr.	1c.	
Boston, "		1c.	20c.
Bridgewater, "		1c.	20c.
Lansing. Prior to 1888	75c. to 9 P.M. 1.00 to 12 P.M.		
Syracuse, N. Y.			10c.
Little Rock, Ark.		1c.	
Colorado Sp., Col.		1c.	
Leadville, Col.	$1.	1¼c.	
Logansport, Ind.		1c.	
San Jose, Cal.		1¼c.	
Baton Rouge, La.	50c.		
Marseilles, Ill.	40c.		
Chicago, Ill.		1c.	
Wichita, Kas.		1c.	
Topeka, Kas.		1c.	
St. Louis, Mo.		1-1¼c.	
Duluth, Minn.		1c.	
Springfield, Mo.		1c.	
Bath, Me.		1c.	
Birmingham, Conn.			20c.
Omaha, Neb.			20c.
Binghamton, N. Y.		1c.	
N. Y. City, N. Y.		1c.	
Brooklyn, N. Y.		1c.	
Cincinnati, O.		¾c.	15c.
Mt. Holly, N. J.		½c.	
N. Brunswick, N. J.		8/10	16c.
Washington, D. C.			18c.
Philadelphia, Pa.		¾c.	18c.
Harrisburg, Pa.			18c.
Wilmington, Del.	10c. not over 1 hr., $1 lamp; 60-80c. for 3 or more.	6/10c.	

The figures for Massachusetts are taken from the Report of the Gas and Electric Light Commissioners. Those for cities outside Massachusetts are from reports made to me or to the South Norwalk Investigating Committee, or they have been collated by Mr. Parsons, in the "Arena," August, 1895.

A comparison of these rates shows that private companies charge for commercial lighting fifty to one hundred per cent. more than municipal plants. The lowest meter rate charged by private companies is in Syracuse—ten cents per kw.—whereas the usual rate is twenty cents per kw., or its equivalent, one cent per meter hour. The lowest rate charged by cities is three-tenths of a cent per lamp hour in Newark, Delaware, but the usual rate is one-half cent per meter hour, and seven to ten cents per kw.; and thirty-five to fifty cents per month against seventy-five to one dollar and twenty-five cents per month with private companies.

TABLE XI.

NET COST OF PUBLIC LIGHTING PER K. W. TO CITIES HAVING COMMERCIAL PLANT.—FOSTER.

City.	Cost per k. w. for total output.	Net cost per k. w. used by city after deducting commercial lighting.	Cost to cities by private companies.
Santa Cruz, Cal.	$0.2473	$0.2620	$0.115
Portland, Ore.	.0960	.0913	.077
S. Norwalk, Conn.	.0528	.0019	.081
Frederick, Md.	.0569	.0565	.053
Metropolis, Ill.	.1324	.1770	.091
Council Grove, Kan.	.0884	.0259	.082
Arlington, Minn.	.0975	.0149	.046
Crawfordsville, Ind.	.0758	.0830	.078
St. Clairsville, O.	.1540	.2160	.104
Little Rock, Ark.	.0561	.0011	.041
High Point, N. C.	.1470	.1760	.065
Marshalltown, Ia.	.0483	.0617	.080

Ashtabula, O.	.1095	.1870	.162
Blue Island, Ill.	.0956	.1294	.095
Averages	.1009	.1105	.086
Same in lamp hours, 2,000 c. p. 480 watts	.0484	.0579	.041
Total cost per lamp hour, 2,000 c. p. for street plants alone...	.0444	....	....

That municipal rates are much lower than private rates is beyond question. Mr. Francisco cannot disprove it either by screwing the figures or inflating depreciation. He therefore complains that the taxpayers are being oppressed for the benefit of the consumers; and Mr. Foster gives a table showing that where the city does commercial lighting, the net cost to the city for its street lights is greater than where it does street lighting alone, which is explained, he says, by the extremely low prices for commercial work. The table is reproduced herewith.

I will show below how this table is compiled and of how little value it is. Suffice it here to say that the cities doing commercial lighting very generally report that their street lights cost them, net, much less on account of the commerical profits than they did without the latter.

PROFITS VS. REDUCED COST.

In the operation of a commercial plant it is a question of policy whether the city shall make a profit and so reduce the cost of street lighting to the taxpayers, thus taxing consumers for the benefit of taxpayers, or shall furnish the light to consumers below cost, thus taxing the taxpayers for the benefit of consumers. I assume that the nearest approach to justice is attained when each service pays its own way. Consumers should pay for what they get at its net cost price, and taxpayers should pay for street lamps at their cost. If this principle be adopted, depreciation should be charged under the operating expenses of the plant, and should be actually written off from the capital from year to year; the taxable property of the city should be assessed a fixed rate per lamp for all street lamps, the proceeds of which should be debited by the electrical administration as regular income along with the commercial income, and from the two together should be deducted operating expenses, leaving a "profit and loss" or "net revenue" account, which in turn should be credited with interest on bonds, depreciation and sinking fund.[1]

Our cities are justly charged with inferior and loose business methods, and nowhere is reform more needed than in the bookkeeping. Fair-minded opponents agree that the city has the advantage in operation of industry, especially in the low rate of

[1] Municipal Affairs, Dec., 1897. A Reply to R. R. Bowker. See Elec Engr.

[1] An admirable example of this method of municipal bookkeeping may be found in the electric light accounts of the City of Aberdeen, Scotland. Upon consultation, one will find that the city is charged for 14 lamps, consuming 11,057 k. w., £209 8s. 5d., which is a rate of 9.1 cents per k. w. for public lighting, while private consumers are charged 10 cents (5d.) per k. w. It will also be seen that the depreciation is charged at 5 per cent. on machinery and meters, 2½ per cent. on electrical instruments, 1⅓ per cent. on mains, and 1 per cent. on buildings, making an aggregate for the year 1896 of £844 19s. 7d., or a total rate on the entire expenditure at the beginning of the year of 2.7 per cent. Furthermore, by examining the "state of capital account" from 1894 to 1896, it will be seen that at the balancing of each year's accounts new construction is added and depreciation written off, so that the net balance at the close of 1896 is £34,780 5s. 5d., instead of £36,620 15s. 9d., the aggregate expenditure.

interest which it pays on loans, and the strength of their argument lies solely in attacking the looseness of methods and the incompetency, not to say corruption, of officials. Admitting that their attack is in most cases justified, the advocate of city ownership must point the way to a remedy or abandon his cause. The first step is better methods of municipal bookkeeping. It becomes especially urgent, when the city enters upon the field of commercial lighting, and it becomes important to apportion properly the expenditures between taxpayers and consumers. This urgency increases with the size of the city, where consumers outnumber taxpayers. We may conclude that as far as bookkeeping itself is concerned, a depreciation of three per cent. on the total cost of the plant is ample to cover costs, and on this basis the rates to consumers should be fixed. Three per cent. on the entire capital, compounded at four per cent.—the rate of interest paid by cities—would replace the principal every twenty-one years. This rate is amply justified, not only by the Aberdeen accounts, but also by the figures of other European cities. Glasgow, without carrying insurance, wrote off depreciation in 1894 of three and seven-tenths per cent.; in 1895 of three and nine-tenths per cent.; in 1896 of four and eight-tenths per cent.; Dublin, in 1897, nine-tenths of one per cent.; Bradford, 1897, two per cent.; Manchester, 1897, wrote off a depreciation of £5,000, equal to one and six-tenths per cent. on the capital of £309,190, but from this amount deducted repairs and renewals of £1,692 19s. 8d., leaving a net depreciation of £3,307 0s. 4d., equal to one and one-tenth per cent. The strong conservatism of these English cities makes it quite certain that they have placed depreciation at the highest rate justifiable.

ELECTRIC TRANSPORTATION

Brown Electric System on the Capital Railway Co's Lines.

THE Capital Railway Company, of Washington, D. C., which operates cars between the U. S. Navy Yard and suburbs known as Congress Heights, has the "Brown" surface contact system installed for a very short distance, between the Navy Yard and the Annacostia Bridge. Lately some trouble has arisen between the company and the District Commissioners over the methods used by the company on this short stretch of experimental road; the system on crossing the bridge being the overhead trolley. The "Brown" system is as follows: Every eight feet an iron surface contact plate projects above the ground between the rails, shown in Figs. 1 and 2. Under this plate is a hard burned material carrying a porcelain cup partly filled with mercury upon which a steel ball floats. The cars carry electro-magnets excited by storage batteries which attract the steel balls on passing over them and close the circuit under the car. These porcelain cups break by the jumping up of the balls and allow a current to flow between the surface contact plates and the rails, see Fig. 2, which is objected to by the commissioners. The commissioners have allowed ninety days to perfect

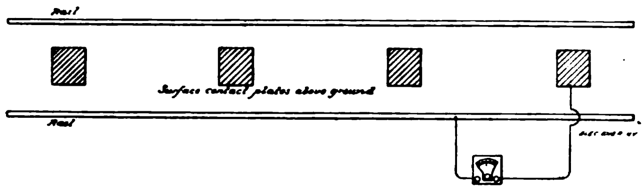

FIG. 2.—"BROWN" SURFACE CONTACT SYSTEM.
(When mercury cups break a d. of p. exists between rail and surface contact.)

these cups and stop the leak, which is very small but objectionable. When the cups are perfected and the "Brown" system is demonstrated in the district, the commissioners intend to insist on the equipment of the road with a metallic return, because of electrolysis. In addition to these exactions by the commissioners, the contact plates must be moved from the centre of the track,

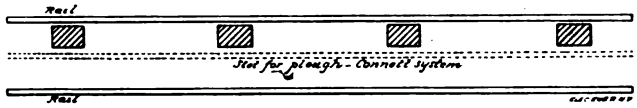

FIG. 3.—NEW POSITION OF SURFACE CONTACT PLATES IN ORDER THAT A SLOT AND CONNETT SYSTEM MAY BE INSTALLED IN ADDITION.

to one side, in order that the "Connett" slot system may be installed in addition, as shown in Fig. 3. This is done in order that other cars may run on the same track, the commissioners not allowing two sets of track on any one street.

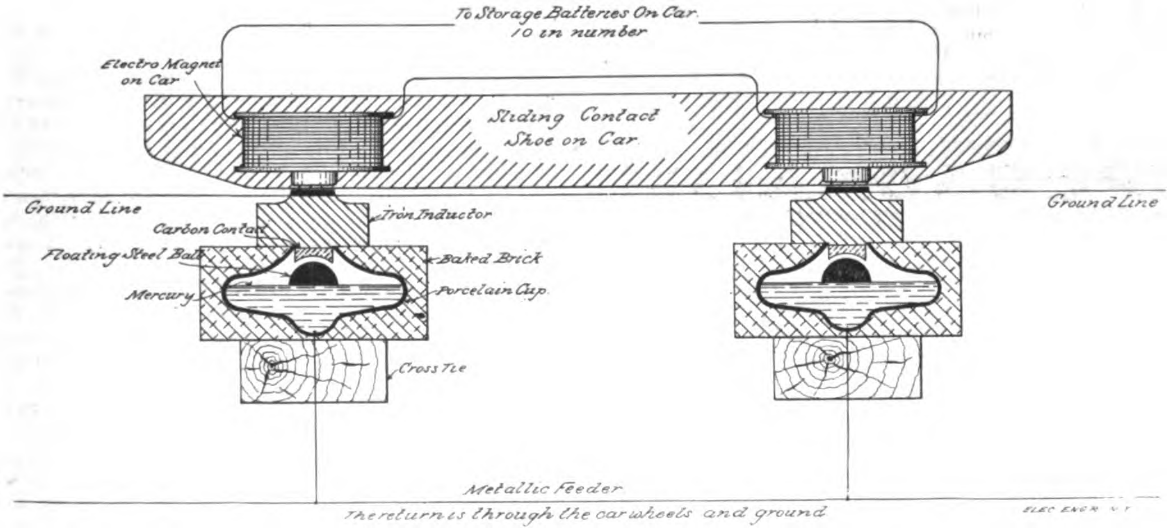

FIG. 1.—"BROWN" SURFACE CONTACT RAILWAY SYSTEM; SECTION THROUGH SHOE AND CONTACT PLATES.

will be established. This system will be equipped with electricity. The contract embracing these changes has been signed for a term of fifty years.

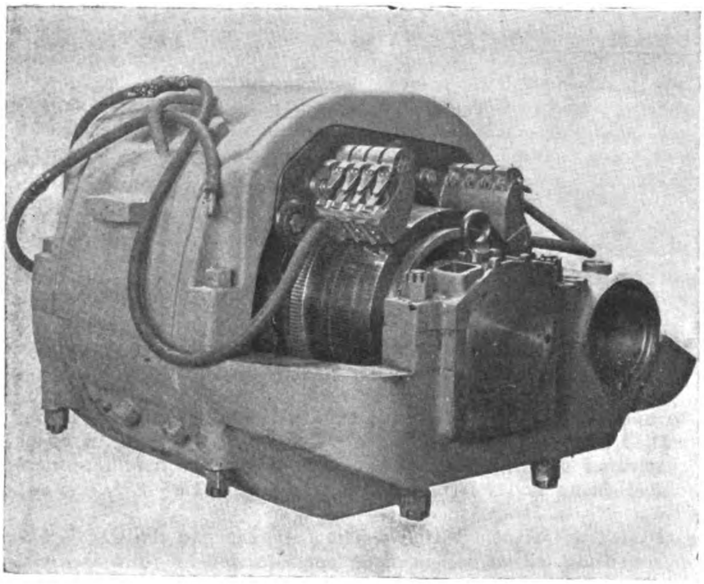
PORT HURON, MICH.—The City Electric Railway is experimenting with a ball bearing truck devised by John Deloyia, of that town.

BROOKLYN.—An arrangement has been made between the Long Island Railroad and the Brooklyn Elevated Railroad by which through trains will ultimately be run from the New York entrance of Brooklyn Bridge, without change of cars, to Jamaica, to Rockaway Beach, and to Coney Island. These destinations can also be reached via the Broadway ferry and the Broadway line of the Brooklyn Elevated by connections which will be established. This system will be equipped with electricity. The contract embracing these changes has been signed for a term of fifty years.

M. SOULECROUP, assistant superintendent of motive power of the Paris and New Orleans Railroad, has been in this country with a corps of five experts studying electrical methods. He has recently been inspecting the work in the B. & O. tunnel at Baltimore.

Walker Elevated Railway Motor.

THE Walker Company has recently placed on the market a very powerful elevated railway motor, an illustration of which is shown below. Power considered, this motor is a marvel of lightness and compact construction. Two such motors may be installed on an ordinary standard gauge 33-inch wheel, 6-foot wheel base bogie truck, thus making it easily possible to equip a car with from 600 to 700 horse power. Such a car can do tractive work that will compare favorably with the ordinary passenger locomotive. This motor was designed for elevated work, and has given great satisfaction in such service, and it will operate equally well over a clean stone ballasted interurban line. Being, however, of open construction, it is not suited for work



WALKER ELEVATED RAILWAY MOTOR.

on street car lines, where mud and dust demand greater protection. The Metropolitan West Side Elevated Road in Chicago is being equipped with these motors, which are known as the Walker 20 L., while a smaller size of the same type known as the 15 L. is being built for the equipment of the Brooklyn L.

Among other roads using the heavy Walker motors may be mentioned: The Rapid Railway, of Detroit; the Sutro Railway, San Francisco; the Suburban Railway, Chicago; the Anaconda Electric Railway, Anaconda, Mont.; and the East St. Louis and Belleville (now building), besides many others.

PERSONAL

Mr. Charles A. Boyd.

Mr. Chas. A. Boyd, Superintendent of the Walker Company of Cleveland, has resigned his position, to take effect April 12. He will enter business for himself, doing general engineering, with offices in the American Trust Building, Cleveland, Ohio. Mr. Boyd has been with the Walker Company for the past four years, starting as engineer in the railway motor department, having charge of the design and construction. About one year later he was placed in charge of the entire engineering department, and was promoted to the position of assistant superintendent on January 1, 1897. The following March he was appointed superintendent of the Cleveland works, having in charge both the engineering department and shops.

MESSRS. SELLON and HODGKIN, of the Brush Engineering Co., of England, sailed for home last Saturday.

MR. C. F. HUTCHIGS, formerly superintendent of the Wilmington, Del., City Railway Co., has been appointed superintendent engineer by the United Alkali Co., of Bay City, Mich., and has entered upon his new duties.

MR. LUTHER STIERINGER, the consulting electrical engineer of the Omaha Exposition, has returned to New York for a brief stay to attend to pressing personal matters and arrange for some important details in regard to leading exhibits there.

NEWS AND NOTES

How the Spaniards Blew Up the Maine.

Mr. J. P. Gibbins, in a signed communication to the New York "World," from London, dated April 7, states that he supplied the Spanish Government with 56 ground mines and 25 buoyant mines, each charged with 500 pounds of guncotton; and 15 electro contact mines, each charged with 100 pounds of guncotton. There was also a latter order. Mr. Gibbins asserts that he himself shipped some of these mines to Havana, from the West India Dock, London, on a Spanish Government vessel. He expresses his belief, with reason therefor, that the "Maine" was blown up by a mine operated by Spanish officers, who alone could have control and knowledge of the apparatus, and adds: "I have not the slightest hesitation in saying that the 'Maine' was deliberately destroyed with a 500-pound ground mine, as invented and supplied by me." Mr. Gibbins enters into the precautions necessarily taken in firing such electrical mines, and shows how their very complication is intended to avoid all possibility of accident or meddling.

It is understood that evidence is being adduced showing the connection of the electric lighting system of Havana into the circuits running to the mines, for the purpose of furnishing the required current quickly.

Preparations for War.

Frank J. Sprague, Vice-President of the Sprague Electric Company, is organizing an emergency corps of electricians and electrical engineers to work in conjunction with the State Naval Reserve in the event of hostilities. Mr. Sprague is a graduate of the Annapolis Naval Academy. He has communicated his plan to the Assistant Secretary of the Navy and says it has received Mr. Roosevelt's indorsement and that of Captain Jacob W. Miller, Commander of the Naval Reserve of New York. Mr. Sprague invites electricians and engineers who want to join the proposed auxiliary corps to write to Room 1511, Commercial Cable Building, stating age, address, and place of employment. Unmarried men are preferred.

As already announced in these columns, Captain Eugene Griffin, late U. S. A., first vice-president of the General Electric Co., with the approval of the Secretary of War and the Chief of the Engineer Corps, Brigadier General J. M. Wilson, has undertaken the formation of a Volunteer Electrical Corps. He obtained a list of the most skilful workmen in the employ of his own company and informed each of them what he wanted and asked if they would volunteer for the service. Captain Griffin made it clear that in case of war the volunteers might be called upon to make needed repairs on warships after their service in the army was over. He also stated that, in case the Government had need of their services, they would draw their pay from the company during all the period of service, as well as pay from the Government, with the privilege of going back to their old jobs when the war was over. He then wrote to other electrical companies in this city telling them what he wanted to do and what he had done and asked them to co-operate with him. To electrical companies in Boston and Philadelphia he sent similar communications. The quickness with which the replies came was astonishing. From his own men Captain Griffin received the most loyal responses. Everybody to whom he wrote wanted to volunteer. In this vicinity Captain Griffin has received favorable replies from the United States Electrical Supply Company, from the Edison Electric Company of Brooklyn, from the Mount Morris Electric Light Company, from the Manhattan Electrical Supply Company and from the Westinghouse Company. From Boston came responses from the Edison Illuminating Company, the Marlborough Electric Light Company, from the Bell Telephone Company and the Boston Telegraph Company. A number of Philadelphia companies also

responded. The result was that in less than a week more than 1,000 men had been enrolled. Captain Griffin obtained the day and night address of every volunteer. These were sent to the office of the Chief of the Engineers' Corps at Washington, where they are now on file. In Baltimore, Dr. Louis Duncan has been doing similar active work with excellent results.

The Westinghouse Electric Mfg. Company has begun shipment to the Brooklyn Navy Yard, of large quantities of generators, motors, dynamos and wires. They are to be used for the installation of electric power and light plants on board the merchantmen, old monitors, and coasting steamers now being equipped by the Government for service in case of war with Spain. The order is for $682,000 worth of such material, and the company will receive a bonus of $25,000 for prompt delivery. Shipments will be made every day this week.

Mr. W. R. Brixey, owner of Day's Kerite, is running his factory at Seymour, Conn., night and day on Government orders for insulated wires and cables.

The Pennsylvania Electric Company of Marietta has received a large order for telephones from the War Department, to be used for all the forts, coast defence and signal stations along the Atlantic coast. The company received instructions to rush the order. This is quite a compliment to the Crescent Telephone apparatus.

The Growing List of Exhibitors for the Electrical Exhibition.

IN our issue of February 17, we published a preliminary list of exhibitors for the May Exposition. We are now able to present a revised list, for which we are indebted to the manager, Mr. Marcus Nathan. It is as follows:

Armorite Interior Conduit Co., Pittsburg, Pa.
American Rheostat Co., Milwaukee, Wis.
American Pulley Co., Philadelphia, Pa.
American Watchman's Time Detector, 234 Broadway, N. Y.
American Engine Co., Bound Brook, N. J.
Adams-Bagnall Electric Co., Cleveland, Ohio.
Armington & Sims Co., Providence, R. I.
American Electrical and Maintenance Co., 451 Greenwich Street, N. Y.
American Electrician Co., New York.
American Electrical Works, Providence, R. I.
American Electric Novelty & Manufacturing Co., 231 Broadway, N. Y.
American Circular Loom Co., Boston, Mass.
Bullock Electric Co., St. Paul Building, New York.
Bossert Electric Construction Co., Utica, N. Y.
Baylis Co., The, 99 Cedar Street, N. Y.
Borne, Scrymser Co., 80 South Street, N. Y.
Belknap Motor Co., Portland, Me.
Brewster Engineering Co., 27 Thames Street, N. Y.
Barrows & Co., C. H., 302 West 53d Street, N. Y. (Electric Vehicles.)
Broomell, Schmidt & Co., York, Pa.
Boston Electro Duct Co., Boston, Mass.
Burhorn & Granger, 136 Liberty Street, N. Y. (Woodbury Engine.)
Babcock & Wilcox Co., 29 Cortlandt Street, N. Y.
Crocker-Wheeler Electric Co., 39 Cortlandt Street, N. Y.
C & C Electric Co., 143 Liberty Street, N. Y.
Corey, R. B., 26 Cortlandt Street, N. Y.
Coho & Co., H. B., 220 Broadway, N. Y.
Card Electric Co., Mansfield, Ohio.
Camp Co., H. B., Aultman, Ohio.
Cleveland Twist Drill Co., Cleveland, Ohio.
Crouse-Tremaine Carbon Co., Fostoria, Ohio.
Crown Woven Wire Brush Co., Salem, Mass.
Cook's Sons, Adam, 313 West Street, N. Y.
Cutter Electrical & Manufacturing Co., Philadelphia, Pa.
De La Vergne Refrigerating Machine Co., 138th St. and East River, N. Y. (Hornsby-Akroyd Oil Engine.)
Diamond Electric Co., Peoria, Ill.
Diesel Motor Co. of America, 11 Broadway, N. Y.
Edison, Thomas A., Orange, N. J., per W. S. Mallory.
Edison Manufacturing Co., Orange, N. J.
Edison, Jr., Thomas A., 96 Broadway, N. Y.
Edison Electric Illuminating Co., of N. Y., Duane and Elm Streets, N. Y.
Eddy Electric Manufacturing Co., Windsor, Conn.
Electric Storage Battery Co., Philadelphia, Pa.
Excelsior Electric Co., Brooklyn, N. Y.
Electrical Engineer, New York.
Electrical Review, New York.
Electrical Age Publishing Co., New York.
Electricity Newspaper Co., New York.
Electrical World, New York.
Elliott & Hatch Book Typewriter Co., 253 Broadway, N. Y.
Electrical Engineer Institute of Correspondence Instruction, 120 Liberty Street, N. Y.
Fischer Foundry & Machine Co., Pittsburg, Pa.
Fort Wayne Elec. Corporation, Fort Wayne, Ind.
Fuel Economizer Co., Matteawan, N. Y.
Fostoria Incandescent Lamp Co., Fostoria, Ohio.
Fiberite Co., Mechanicsville, N. Y.
Fairchild & Sumner, 39 Cortlandt Street, N. Y.
Francis Bros., Philadelphia, Pa.
Gold Car Heating Co., Cliff and Frankfort Streets, N. Y.
Garton-Daniells Electric Co., Keokuk, Ia.
Garvin Machine Co., Spring and Varick Streets, N. Y.
General Incandescent Arc Light Co., 33d Street and 1st Avenue, N. Y.
Griffing Iron Co., A. A., Jersey City, N. J.
Harrison Safety Boiler Works, Germantown Junction, Philadelphia, Pa.
Highland Chemical Co., Connellsville, Pa.
Haines Co., Wm. S., Philadelphia, Pa.
Haring Steam Plant Equipment Co., 26 Cortlandt St., N. Y.
Hope Electric Appliance Co., Providence, R. I.
Ideal Electric Corporation, 13th and Hudson Sts., N. Y.
Imperial Porcelain Works, Trenton, N. J.
India Rubber & Gutta Percha Insulating Company, Glenwood, N. Y.
International Arc Lamp Co., Mercer and Houston Streets, N. Y.
Jones & Son, J., 60 Cortlandt Street, N. Y.
Keuffel & Esser Co., 127 Fulton Street, N. Y.
Kelley & Sons, B. F., 91 Liberty Street, N. Y.
Keystone Elec. Inst. Co., 9th St. and Montgomery Ave., Philadelphia, Pa.
Kelley & Mueller, 7 West 13th Street, N. Y.
Kosmic Oil Filter Co., Easton, Pa.
K. & W. Company, Pittsfield, Mass.
Katzenstein & Co., L., 357 West St., N. Y.
Kensington Engine Works, Ltd., Philadelphia, Pa.
Kirkland, H. B., 120 Liberty Street, N. Y.
Lewis Tool Co., 44 Barclay Street, N. Y.
Lynn Incandescent Lamp Co., Lynn, Mass.
Morris, Elmer P., 15 Cortlandt Street, N. Y.
Machado & Roller, 203 Broadway, N. Y.
Mowrey, P. M., & Co., 318 Broadway, N. Y.
Monarch Manufacturing Co., Waterbury, Conn.
Niles Tool Works Co., Hamilton, O., and New York.
National Meter Co., 118 Chambers Street, N. Y.
Nowotny Electric Co., Cincinnati, Ohio.
National Carbon Co., Cleveland, Ohio.
Nash Gas Engine Co., 99 Cedar Street, N. Y.
New Britain Machine Co., New Britain, Conn.

Instruments of Precision at the Exhibition.

The Brooklyn Polytechnic Institute, and Dr. Samuel Sheldon, its Professor of Physics and Electrical Engineering, have kindly loaned the Electrical Exhibition several interesting units and standards upon which precision in electrical measurements is based. Even the electric public, while it hears a great deal of such standards, rarely sees them, and this exhibit, therefore, will be at once of technical and popular interest. The exhibit will include especially some standards from the German Imperial Physico-Technical Institute (Reichsanstalt), whose celebrated work has been done under the guidance of such men as Helmholtz and Kohlrausch; and it is probable that these standards have never before been exhibited in public in this country. Dr. Sheldon will show the Reichsanstalt form of the standard Clark cell, the Reichsanstalt pattern of photometer with Hefner amyl-acetate standard lamp, and Lummer Brodhun contrast screen; standard .01 ohm for carrying heavy currents; large standard compensation set for the precise comparison of voltages from

.01 to 1,200 volts and currents of any magnitude; standard Wheatstone bridge; Thomson's double bridge for conductivity measurements; standard Carhart-Clark cell, etc. The exhibition of such apparatus, and the explanation given as to its use will do much to bring electrical measurements within the comprehension of the public, and to demonstrate the wonderful refinement of accuracy that modern electricians aim at in their apparatus.

Stationary Engineers at the Exhibition.

Arrangements have been made through Mr. W. T. Wheeler, Vice-Pres. Nat. Assn., and member of the Exhibition Auxiliary Committee, for the meetings of about fifty associations of the N. A. S. E. These associations will come from New York, New Jersey, Pennsylvania, Massachusetts, Rhode Island and Connecticut. Several rooms suitable for meetings have been provided and the various lodges invited almost without exception have accepted the invitation and will hold their regular meeting nights as the guests of the Exhibition Company. It is expected that there will be an attendance of at least 5,000 practical engineers (two lodges every evening), and the exhibition management is arranging a registry system with bulletin boards in different sections of the building, so that exhibitors may know just what associations of engineers are present and the plants with which they are connected.

Sprague Electric Co's. Exhibit.

The Sprague Electric Company have reserved sufficient space for a very comprehensive exhibit of their product at the Electrical Exposition. The exhibit will comprise a type of each Sprague electric elevator manufactured by that concern; a direct connected lighting plant; Lundell power and fan motors; exhaust fan outfits; a printing machine in operation, together with blowing outfit; a cab of the London type with automobile motor and Sprague controller; screw pumps; armatures; conduit; switchboards and conduit racks. The Sprague Company promises to make as complete an exhibit as has ever been made in their particular line.

LEGAL NOTES

Decision by U. S. Circuit Court of Appeals Against Under-Running Trolley Patent.

UNITED STATES CIRCUIT COURT OF APPEALS. SECOND CIRCUIT. THOMSON-HOUSTON ELECTRIC COMPANY, Appellee, vs. UNION RAILWAY COMPANY, et al, Appellants.

PER CURIAM.—This appeal involves the question whether Claims 2 and 4 of Letters Patent No. 495,443 for "traveling contact for electric railways," granted April 11, 1893, to the administrators of Charles A. Vandepoele, assignors to the complainant, are void because they are for the same inventions which had been previously patented in Letters Patent No. 424,695. The invention, to adopt the language of an expert witness for the complainant in a former suit brought upon the patent, "consists generally in an electric railway, having an overhead conductor, and a car for said railway provided with a contact device carried by the car so as to form a unitary structure therewith, and consisting of a trailing arm hinged and pivoted to the car so as to bridge the space between it and the conductor, and move freely both laterally and vertically, and said arm carrying at its outer end a contact device capable of being pressed upward by a suitable tension device into engagement with the under side of the conductor." The essential features of construction involve the location of the supply conductor above the track and line of travel of the car and contact with its under side; the arrangement of the contact device on a trailing arm; and the maintenance of a constant upward pressure by means of a tension device operating upon a hinged arm. The two claims in controversy are:

2. "The combination of a car, an overhead conductor above the car, a contact device making underneath contact with the conductor, and an arm carried by the car and carrying the contact device, and pivoted so as to swing freely around a vertical axis."

4. "The combination of a car, an overhead conductor above the car, a contact device making underneath contact with the conductor, and an arm on the car movable on both a vertical and a transverse axis and carrying the contact device."

The patent contains sixteen claims. The characteristics of the invention and the scope and validity of many of the claims were considered by this court in Thomson-Houston Electric Company vs. Hoosick Railway Company (82 Fed. Rep., 461), where we held that Claims 6, 7, 8, 12 and 16 were for the same inventions which had been previously patented; and a reference to the opinion in that case will dispense with the necessity for any extended discussion now. Referring to some of those claims we said: "It would be a waste of time to dwell upon the verbal differences in these claims. The changes in phraseology import nothing of substance into their respective combinations. They describe the same thing in different language." It is insisted for the appellants that the two claims now in controversy are for the same combinations specified in some of the claims which were then held to be void. The appellee contends that they are not because they omit to specify any means for holding the contact device in underneath contact with a conductor, and consequently can be construed as covering a sub-combination in which such means are not employed, or if such means must be read into the claims by implication the claims are not limited to the means described in the specification, and that upon either construction they are not the claims of the earlier patent. The court below adopted this view. If the appellants are right no other question need be considered. It will be seen that these claims are for identical combinations except that the arm is differentiated in each by functional characteristics. The specification describes a traveling arm carried by a post on top of the car "which is hinged and should in most instances be also pivoted to the top of the post, although a reasonable amount of looseness in the hinged joint will answer the purpose of the pivot." When pivoted "it swings freely around a vertical axis," and meets the terms of Claim 2. When hinged and loosely jointed, it is "movable on both a vertical and transverse axis," and meets the terms of Claim 4. We do not entertain any doubt that there must be incorporated into these claims, by implication, means for maintaining the contact device and the conductor in their normal working relations. Without them there is really no "traveling" contact device, and no operative combination; and the claims would cover merely an aggregation of devices which do not co-act unless assisted by some instrumentality which must be discovered and supplied. The function of the arm as constructed and arranged is to establish "moving contact" while maintaining a positive mechanical connection between the vehicle and the conductor. It was devised because as previously mounted the contact was found to be deficient in compacity to follow the sinuosities and deflections of the conductor while the car was in motion. It can only perform this function by the aid of some instrumentality which holds it constantly in the proper relations to bridge the space between the car and the conductor and keep the contact device and the conductor in electrical connection. As pointed out in the specification, this consists of a tension device operating upon the arm and maintaining a constant upward pressure, thus holding the contact device to the conductor. This tension device, or its equivalent, is an indispensable element of the respective combinations.

That the proper construction of the claims is as thus indicated is evidenced upon the proceedings upon interference in the Patent Office. Claim 2 is a literal statement of the issue defined and formulated by the Patent Office between what was then Claim 1 of the application and the claims of two interfering applications. Claims 1 was as follows: "In an electric railway, the combination with a suitable contact and the supply conductor suspended above the track, of a car provided with a swinging arm carrying a contact device in its outer extremity and means for imparting upward pressure to the outer portion of the arm and contact, to hold the latter in continuous working relation with the under side of the supply conductor substantially as described." In formulating the issue the office omitted as unnecessary, because necessarily implied, the elements enumerated in Claim 1 of the application which are not enumerated in Claim 2 of the patent. One of these elements was "means for imparting upward pressure to the outer portion of the arm and contact." This element was apparently thought to be as indispensable to the operativeness of the combination of the claim as was "a suitable track," an element also omitted.

The appellee concedes that the claims are for combinations specified in other claims of the patent, which by our former decision were held to be void, if they require the construction

which we have placed upon them. Indeed Claim 6, which we held to be void, is identical in terms with Claim 1 of the interference proceedings, the claim which the Patent Office regarded as embodying the invention covered by present Claim 2. The rule of construction which usually obtains whereby several claims of a patent are to be differentiated, so that effect may be given each, can not be reasonably invoked in behalf of this patent where so many of the claims are duplicated.

The order granting a preliminary injunction is reversed.

Judges Wallace and Shipman constituted the court.

The counsel who argued the case were:

For Walker Co.

Charles E. Mitchell, of Mitchell, Bartlett & Brownell, and Wm. Houston Kenyon, of Witter & Kenyon.

For General Electric Co.

F. H. Betts, of Betts, Sheffield & Betts, and F. P. Fish.

Telephone Switchboards.

United States Judge de Haven sitting in the United States Circuit Court has decided that the Western Electric Company is entitled to an injunction restraining the Capital Telephone and Telegraph Company from the use of the Perrin multiple switchboard. The court also ordered an accounting. The switchboard used by the defendant was invented by Thomas J. Perrin and was patented in April, 1885. The court found that Leroy B. Firman had reduced his invention of a multiple switchboard to practice early in 1879 and several months earlier than the other patent.—San Francisco Call.

SOCIETY & CLUB NOTES

Canadian Electrical Association.

A well attended meeting of the Executive Committee of the above association was held at the office of the secretary, Mr. C. H. Mortimer, Confederation Life Building, Toronto, on the 5th inst., to further arrangements for the annual convention which is to be held in Montreal.

The dates chosen for the convention are Tuesday, Wednesday and Thursday, the 28th, 29th and 30th of June. The headquarters of the association during the convention will be at the Windsor Hotel, where the business sessions and the annual banquet will also be held.

The draft programme recommended by the local committee of arrangements, with some slight amendments, was adopted, and is as follows:

First Day.—Executive meeting 9.30 to 10 a. m.; session, 10 a. m. to 1 p. m.; session, 2 to 5 p. m.; 7.30 p. m.; trip around Mount Royal by special Park and Island cars, afterwards ascending Incline railway to lookout on mountain to view the city under illumination.

Second Day.—Session, 9 to 12, noon; cabs and busses from Windsor Hotel at 1 p. m. to visit; (1) Bell Telephone Company's new building; (2) Street Railway Company's power house; (3) power house and works of the Lachine Rapids Hydraulic & Land Co., returning to city at 7.30 p. m.; 9 p. m., annual banquet of Association at Windsor Hotel.

Third Day.—Session, 9 to 12 a. m., election of officers and visit to McGill University; 1.30 p. m., visit to Royal Electric Company's lighting station and factory, then by special G. T. train to visit the work of the Chambly Manufacturing Company at Chambly.

A number of very interesting and instructive papers relating to various phases of electrical work have been promised, and are in course of preparation.

Negotiations are in progress with the object of securing special transportation rates to enable a large number of the Western members to participate in the proceedings of what will undoubtedly be a very pleasurable and instructive occasion.

THE COLUMBIA UNIVERSITY TEA on Saturday, April 16, will take place in the Physics and Engineering Buildings, from three until six p. m.

New Members of the New York Electrical Society.

Secretary G. H. Guy reports the following list of over fifty new members elected March 30: W. C. Broadhurst, H. M. Lamont, C. Morris Haskell, Edwin H. Daly, Gustavo Lobo, Richard Lamb, J. B. Taltavall, Fred Catlin, Clarence W. Phillips, Marcus Nathan, Harris I. Goldstein, A. L. Saruya, Joseph Miller, Henry C. Mortimer, Earle Ovington, Dr. C. A. Doremus, Geo. F. Porter, A. L. Doremus, Morton Webster Haddock, Richard Koch, H. A. Strauss, F. H. Hawkins, Conrad Wachter, Elmer P. Morris, John Maguire, John Joyce, Jens Skougaard, E. Y. Porter, C. D. Warner, S. Glover Way, Harold Briesen, Christopher M. Lowther, W. J. Clarke, R. E. Gallaher, E. N. Stevenson, Theodore B. Entz, W. H. Palmer, Wm. F. Crawford, C. N. Wheeler, C. W. MacMullen, C. M. Clark, Jos. C. Youenes, Calvin Winsor Rice, L. B. Pearson, Fenton S. Grant, Philip Menges, D. L. Collins, Louis S. Levy, Samuel F. Butterworth, J. J. Bellman, Geo. Sanders Weston, 2d.

NEW YORK ACADEMY OF SCIENCES will hold, in the American Museum of Natural History, its fifth annual reception, with exhibition of the recent progress of science. The days are April 13 and 14.

THE STOCK MARKET

The Strain of Waiting.

Just when this wretched Cuban business is to get into some definite shape, nobody knows at this time of writing, but most people hope it will be ended by ending it. Trade has become quiet where it was brisk and buoyant, and though general business continues excellent, it has a hesitating tone, due to the expectancy of war with all its uncertainties. It is a curious note of the times that bicycle sales in New York and Chicago are said to be the largest on record for the season in any year. The present demand for insulated wires and cables, due in part to Government orders, is also said to be without precedent.

During the week, 8,468 shares of Western Union were sold at higher prices, closing at 86¼, a net gain for the week of 1½. Of General Electric, 5,775 shares were sold, around 32½. New York Edison sold as low as 119, possibly on account of the new issue of stock for extensions. In Boston, American Bell Telephone sold off 4 points to 247.

DR. ELISHA GRAY contributes an article to the "Chicago Herald" on electricity in harbor and coast defense.

DETROIT, MICH. A suit has been brought against the Detroit Telephone Co., etc., for $400,000, for damages, by W. R. Cole, of Mt. Clemens, who claims that his patents have been infringed and his ideas stolen.

PONTIAC, ILL. The Livingston County Telephone Co., J. A. Smith, president; W. E. E. Herron, secretary and general manager, incorporated last February, and equipped with a Stromberg-Carlson system of 500 drops, now has 200 subscribers. It is to build two or three exchanges of about 100 miles toll line each.

CITIZENS' TELEPHONE CO. proposes to operate in New York and New Jersey, under the Martin-Cole duplex system, similar to that in use in Detroit. Mr. D. A. Reynolds represents the company. The rates mentioned are $100 for unlimited service in New York, and $75 for Brooklyn; with a rate of $50 for 500 calls, for "limited service."

PROPOSED CABLE TO HONOLULU. A bill has been introduced in the Hawaiian Senate to authorize the construction of a cable by the Pacific Cable Company, known as the H. Scrymser & Co., whose bill in Congress was favorably reported on by a committee of the House several weeks ago. The bill gives an exclusive cable right to the islands for twenty years. A guarantee of $25,000 in Government bonds is to be put up by the company.

INVENTORS' RECORD

Classified Digest of U. S. Electrical Patents Issued March 29, 1898.

Alarms and Signals:—

ELECTRIC RAILWAY SIGNALING SYSTEM. B. Samuels, St. Joseph, Mo., 601,482. Filed May 6, 1896. Block system. Details of construction.

Batteries, Secondary:—

STORAGE BATTERY. C. S. Kaufmann, Chicago, Ill., 601,471. Filed Sept. 4, 1897. Comprises plates having insulating supports arranged between them provided with T-shaped lower ends and a longitudinal channel, and pins projecting from the faces of some of the plates with their ends received into the channels in the insulating supports.

Conductors, Conduits and Insulators:—

WIRE HOLDER. F. Canfield, Boulder, Colo., 601,412. Filed Oct. 23, 1897. Consists of the combination of a link composed of vulcanized fiber, a saddle of rubber having jaws for embracing the conductor, and a key for clamping the conductor within the saddle.

CLAMPING BUCKLE FOR ELECTRIC LINE WIRES. A. H. Weikman, Palmyra, N. J., 601,454. Filed Dec. 8, 1897. Comprises an elastic fulcrum wire adapted to embrace the insulator and having open projecting ends combined with a pivotally connected lever, and a clamping bail adapted to bend the line wire, and bind the line wire to the insulator.

MEANS FOR SUPPORTING ELECTRIC WIRES. B. D. Smock, Wickatunk, N. J., 601,357. Filed February 10, 1897. Comprises a support carrying two parallel bars to which are fastened line supports, consisting of hooks carried with insulating material.

Distribution:—

SYSTEM OF ELECTRICAL DISTRIBUTION. W. L. Bliss, Brooklyn, N. Y., 601,233. Filed Oct. 14, 1897. Consists in demagnetizing the field of the dynamo, as its speed and e. m. f. increase, by means of an auxiliary counter e. m. f., which increases as the speed and electromotive force of the dynamo increase and which is connected in series with the primary exciting field coil of the dynamo.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. P. F. Krug, New York, 601,268. Filed Jan. 7, 1897. Comprises a supporting stand, a supporting arm provided with a movable fulcrum bearing against the stand, carbon holders and means for supporting and adjusting them, and means for setting and adjusting the supporting arm and its fulcrum.

Measurements:—

MAXIMUM METER. A. H. Hoyt, Penacook, N. H., 601,256. Filed July 29, 1897. A thermal registering maximum meter embodying two strips of thin metal covering opposite sides of the heating area of the thermal tube and electrically connected in parallel, and similarly connected to the stationary and movable parts of the instrument.

Miscellaneous:—

ELECTRIC LIGHTER FOR GAS BURNERS. L. V. Lewitzki, Brussels, Belgium, 601,351. Filed April 15, 1897. Adapted for use on Welsbach burners. Details of construction.

METHOD OF AND APPARATUS FOR PRODUCING CALCIUM CARBID. C. L. Wilson, C. Muma, J. W. Unger, H. Schneckloth, A. P. Brosius and J. C. Kuchel, Holstein, Ia., 601,366. Filed Feb. 13, 1897. Comprises a furnace having a lining of calcium carbid loosely arranged within the furnace wall, means for establishing an electric arc within the furnace and means for feeding lime and carbon into the arc.

ELECTRIC FURNACE FOR MANUFACTURING CALCIUM CARBID. C. L. Wilson, C. Muma, J. W. Unger, H. Schneckloth, A. P. Brosius and J. C. Kuchel, Holstein, Ia., 601,367. Filed Feb. 13, 1897. Consists in the construction of a hollow electrode having at its upper end an insulator provided with openings to communicate with the openings of the electrode and means for raising and lowering the electrode and insulator jointly, so that the operator may by hand feed sticks of lime and carbon into the arc between the electrodes.

CATAPHORIC-ELECTRODE SUPPORT. M. W. Hollingsworth, Philadelphia, Pa., 601,396. Filed Nov. 24, 1897. Comprises an interdental clamp, means for operating the clamp and an electrode holder adjustably connected to the means.

ELECTRIC HEATER. J. F. McElroy, Albany, N. Y., 601,585. Filed Feb. 14, 1895. Comprises supporting brackets carrying a spindle, a core of insulating material having a square perforation adapted to be placed on the spindle, a coiled resistance on the insulating material, and means for holding the same in position.

REGULATOR FOR ORGANS HAVING ELECTRICAL AIR PUMPS. L. K. Fuller, Brattleborough, Vt., 601,318. Filed July 20, 1895. Employs an electric motor for operating the air pump, in combination with a regulator for regulating the volumetric capacity of the air passage between the air chamber and the mouth of the wind-conductor, and means controlled by the organist for governing the regulator.

Railways and Appliances:—

COMBINED RAIL JOINT AND BOND. H. R. Keithley, New York, 601,263. Filed Jan. 3, 1898. Comprises a single metallic piece forged around the meeting ends of two rails, and a bonding plate interposed between the rails and joining piece.

ELECTRIC RAIL BOND. F. W. Atkinson, Chicago, Ill., 601,458. Filed Oct. 4, 1897. Consists of two or more strips of wires which are bent together into two angles to approximately the form of the letter Z, and terminally held together in the same plane by securing-rivets.

Switches, Cut-Outs, Rheostats, Etc.:—

ELECTRIC SWITCH. O. S. Platt, Bridgeport, Conn., 601,276. Filed Feb. 2, 1897. Flush push-button switch. Details of construction.

FUSIBLE CUT-OUT. F. Schwedtmann, St. Louis, Mo., 601,286. Filed May 6, 1897. Consists in a fusible cut-out of porcelain, having the fuse surrounded by some material which will not be injured by the burning out of the fuse.

SAFETY DEVICE FOR ELECTRIC ELEVATORS. J. D. Ihlder, New York, 601,301. Filed Oct. 15, 1896. Combines with the car and motor a potential switch arranged in the circuit of the motor, and a shunt circuit including the magnet of the safety brake device.

AUTOMATIC CUT-OUT. H. F. Blackwell, Jr., Brooklyn, N. Y., 601,492. Filed Aug. 28, 1897. Comprises a spring-actuated arm forming a conductor, a link connected at one end to the arm and at the other end to a part insulated from the arm and a carbon point in the circuit and engaging with the link and adapted to separate the link when heated by an excessive current.

RHEOSTAT. P. E. Pool, Quincy, Ill., 601,588. Filed Jan. 31, 1898. Designed for use in connection with reversible motors for elevator service.

Classified Digest of U. S. Electrical Patents Issued April 5, 1898.

Alarms and Signals:—

HEAT DETECTOR FOR ELECTRIC FIRE ALARM SYSTEMS. J. E. Gould, Brooklyn, N. Y., 601,730. Filed January 30, 1896. Described in detail in issue of January 6, 1898.

Batteries, Primary:—

ELECTRIC LANTERN. O. C. Prasse, West New Brighton, N. Y., 601,758. Filed June 28, 1897. Adapted for bicycle use and comprises a casing having a removable head thereon and a depending cylindrical carbon attached to the head, an inclosed porous cup and a removable zinc contained within the cup, the cup and the said casing adapted for respectively containing chemical compounds, the head having a diagonal vent containing mercury leading there through for the escape of gases.

Conductors, Conduits and Insulators:—

MACHINE FOR RESTORING INSULATED WIRE. N. Wilson, Portland, Ore., 601,694. Filed August 20, 1897. Comprises a straightening device for straightening the old insulated wire, and a stripping device in advance of the straightening device for removing the insulation from the wire.

Lamps and Appurtenances:—

ADJUSTABLE HANGER FOR INCANDESCENT LIGHTS. F. C. Bell, Coeur d'Alene, Idaho, 601,930. Filed March 26, 1895. Details of construction.

Miscellaneous:—

BOWLING ALLEY. E. Brooks, Milton, Mass., 601,626. Filed Feb. 23, 1897. The pin completes an electric circuit connection with an annunciator at the other end of the alley.

SOLENOID BLOW-OUT FOR DISPERSING ARCS FORMED IN BREAKING ELECTRIC CIRCUITS. S. H. Short, Cleveland, Ohio, 601,717. Filed November 1, 1897. Employs a conducting coil having a central open space arranged in proximity to the contacts, being normally in shunt circuit with the contact, and means whereby the coil is introduced into direct circuit at the moment circuit is broken between the contacts.

ELECTRIC WELDING MACHINE. C. Neilson, Brooklyn, N. Y., 601,979. Filed June 15, 1897. Details of construction.

Railways and Appliances:—

RAIL-BOND. J. J. Dainton, Chicago, Ill., 601,707. Filed February 15, 1897. Is provided with tapered terminal sleeves entering tapered holes in the rail web from the larger side of the hole and removably expanded therein by the tapered drift-pins inserted from the same side of the rail-bond.

ELECTRIC BRAKE MECHANISM. A. Vanderbeck, Scarmon, Kan., 601,992. Filed Sept. 13 1897. Employs a magnet provided with contigous spaced poles, and a polarized plunger terminally disposed between the poles and magnet and adapted to be operatively connected with the moving parts of a brake mechanism.

Switches, Cut-Outs, Etc:—

ELECTRO-MAGNETIC CIRCUIT BREAKER. G. S. Dunn, East Orange, N. J., 601,871. Filed June 12, 1897. Comprises an electromagnetic circuit breaker having a latch thereon which permits it to move freely in one direction only, a resistance controlling switch and a part on the resistance controlling switch movable into the path of the latch.

Telegraphs:—

PRINTING TELEGRAPH SYSTEM. J. Burry, Fort Lee, N. J., 601,768. Filed September 10, 1897. A single line wire is employed in operating the type controllers and printing devices of the receivers. Details of construction.

Telephones:—

LOCK FOR TELEPHONES. R. H. Allen, Fitchburg, Mass., 601,786. Filed September 3, 1897. Consists of a base plate and brackets adapted to be secured in proximity to the call means of the instrument, and a swinging arm supported by the base-plate or bracket and adapted to engage the call means and to be locked in engaged position and to be unlocked with a key.

TELEPHONE. T. F. Ahern, Detroit Mich., 601,865. Filed April 26, 1897. The transmitter is suspended on a horizontal axis in a plane parallel to the diaphragm, and so journaled that the speaking tube is normally downward.

DETROIT, MICH.—The Detroit, Ypsilanti & Ann Arbor R. R. has decided to build another power house at Dearborn. It will be a duplicate of the one now building at Ypsilanti, with a complete Westinghouse equipment furnished by the Detroit office of Westinghouse, Church, Kerr & Co., engineers. The finest of cars, 44 feet long, with four 50 h. p. motors on each car, with Westinghouse air brakes, plate glass windows, toilet rooms and plush cushions, etc., will be used on the road.

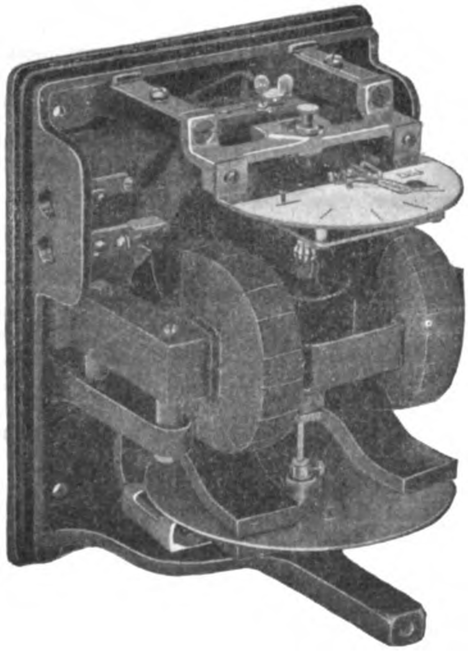
JERSEY CITY, N. J.—The Jersey City Electrical Construction Co. has been formed to carry on a general electrical construction business, with a capital stock of $10,000. The incorporators are H. Chewton, of Paterson; J. McCullough, of Jersey City; and I. M. Simonson, of Paterson.

TRADE NOTES & NOVELTIES

Thomson Recording Storage Battery Meter.

THE increasing application of storage batteries, consequent on their perfection, to electric light and railway station use, as well as to street cars, motor carriages, electric launches, etc., where a portable source of power is requisite, has led the General Electric Company to develop a special type of meter which will show at a glance the amount of energy available in the battery. The Thomson recording storage battery meter resembles in general appearance the standard Thomson recording watt-meter, and is, in fact, a development from it, the mechanism being almost exactly similar. The accuracy and durability characteristic of the standard type have both been maintained, while additional precaution is provided against injury from shock or vibration. The meter is provided with a single indicating needle moving over a horizontal semi-circular dial.

The essential requirement for a storage battery meter is that the armature shall rotate in either direction and give equally accurate readings in both. This requisite is fully preserved. The energy put into the cells is, therefore, added to the reading of the meter, while the energy withdrawn is subtracted, but to compensate for the loss in the cells, the meter runs more slowly when charging. The reading of the meter represents not the amount



THOMSON RECORDING STORAGE BATTERY METER.

of energy put into the battery, but the amount available, and when the needle points to zero on the dial it shows that the battery is completely discharged.

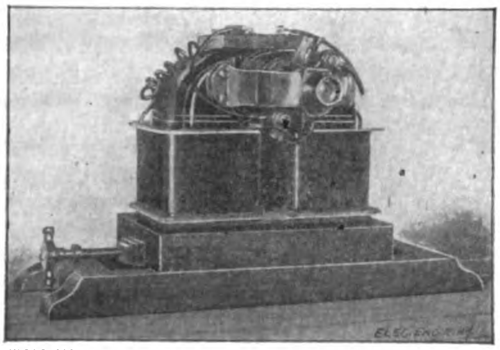
For motor carriage, street car and electric launch service, a meter of this character is a most necessary adjunct. Indeed, any of these vehicles of transportation not equipped with a device to warn the operator of the amount of current available to carry him forward on his journey or to bring him back to his starting point, would be incomplete. Without it he is absolutely ignorant of the power upon which he can depend, and would run serious risk of finding himself at a standstill far from home with no means of getting either forward or backward without recourse to some mechanical method.

The durability and efficient operation of storage cells being maintained by re-charging them before they are exhausted, the only method of learning of their exact condition is by a meter of this character. The cells being re-charged at the right time, the general result is a much higher battery economy.

These meters are manufactured with any desired percentage difference between charging and discharging rates, and in all of the standard sizes in which two-wire Thomson recording watt-meters are built. Since, however, this percentage varies in almost every case, the General Electric Company manufactures them only to order. One size, that reading to 50 amperes, however, may be considered as standard and will be more promptly furnished than any other.

New Apparatus and New Quarters of the Rochester Electric Motor Co.

THE Rochester Electric Motor Company, of Rochester, N. Y., to meet the growing demand for their direct current motors and generators have moved to larger quarters at the corner of Mill and Platt streets, that city, where with the increased room and more machinery they will be in a position to fill their orders more promptly. At present they are working evenings to catch up on their orders. Besides their regular dynamos and motors the company build special machines in the smaller sizes. All their machines embody the following commendable features: Interchangeable field coils, field magnets in one piece, sectional wound armatures, allowing the removal and replacement of single coils in case of accident, self-



THREE H. P. 100 VOLT ROCHESTER MOTOR.

oiling bearings, a combined carbon and copper gauze brush, and heavy insulation of the best quality. Mechanical lock starting boxes of their own design are furnished with their motors. The regular machines are built for 110, 220 and 500 volts and the speeds for the machines are 1,200 revolutions for the ½ to 5 h. p., 900 for the 6 to 8 h. p., 850 for the 12 to 20 h. p., and 500 for the 25 h. p. The company have just built a 3 horse power 100-volt machine, shown in the figure, for the Stecher Lithographing Company, of Rochester, which is direct connected to one of their box machines and will be shipped to London, England. The officers of this flourishing company are F. C. Kimmel, president; Edw. F. Davison, secretary and treasurer; P. J. McDonald, superintendent.

Stagnant Air as a Poison.

The landlocked harbor of Havana, with its narrow opening into the sea but two or four hundred feet wide, is one of the most malignant bodies of water. Although the tide rises and falls there is no circulation of water in the harbor and no fresh water comes in. All of the drainage of Havana goes into the harbor, and at the present time the wharves are so filled with the germs of disease caused by decaying matter and stagnant water that vessels are compelled to unload in lighters rather than risk the danger incurred by tying up to the wharves. The stirring up of the bottom of the harbor produces an effluvia extremely dangerous to the lives of the crews of the ships in the harbor. If this harbor were properly drained and a constant current of fresh water pumped in to replace the foul water, the danger from diseases would be lessened and probably eliminated. Yet in many workshops, school rooms, stores and offices, the air becomes surcharged with carbonic acid gas and gradually loses its proportion of life-giving oxygen until it becomes as foul and dangerous to health as the filthy water in the Havana Harbor, and the people breathing this vitiated atmosphere soon become stupid and inactive. Stagnant air due to want of ventilation is too frequently overlooked, although with better air more work of better character can be done. By the proper use of fan motors the air can be freshened and the injurious effects referred to appreciably lessened, and in many cases entirely eliminated. The modern fan motor in all its different phases from the large exhaust fan to the small desk fan is admirably

fitted for this purpose. The more the public becomes educated regarding the uses and advantages of fresh air and the means of obtaining it so much the better will be the health of the communities wherein the fan motors are employed.

Keuffel & Esser Co.'s Drawing Materials.

KEUFFEL & ESSER CO., 127 Fulton street, New York, manufacturers and dealers in drawing materials and surveying instruments, have recently published a richly illustrated catalogue of over 400 pages, describing their most complete assortment of goods of the highest standard, and is scrupulously exact in its statements and claims. To give some idea of the rich assortment offered by them, we give a number of illustrations of slide rules listed in their catalogue. Slide rules, although invented long ago, have only lately come into a more general appreciation and are now used in nearly all professions and trades, thanks to their improved and simplified form and greater accuracy. Fig. 1 shows the Thacher Calculating Instrument, the most complete slide rule made, containing over 33,000 divisions, and scales 30 and 60 feet in length. The duplex slide rule, Fig. 2, is graduated on both sides, and the slide faces on both sides. A metal runner encircling the rule enables coinciding points of the scales on either face to be at once found. This rule is furnished also in one-half size, with the same number of graduations as the full size. The well-known Mannheim slide rule, shown in Fig. 3, with a celluloid facing, is listed with metal and with glass runner in 5, 10 and 20-inch lengths. The Guntner slide rule, now largely superseded by the Duplex and Mannheim, is of boxwood, and is made only in the 10-inch size. The Student's slide rule, Fig. 4, 10-inch, paper faced, is intended for students who want a low priced rule for instruction and practice. It is not intended for professional use. All these slide rules are furnished with very complete directions, so that their employment does not require a knowledge of logarithms, etc.

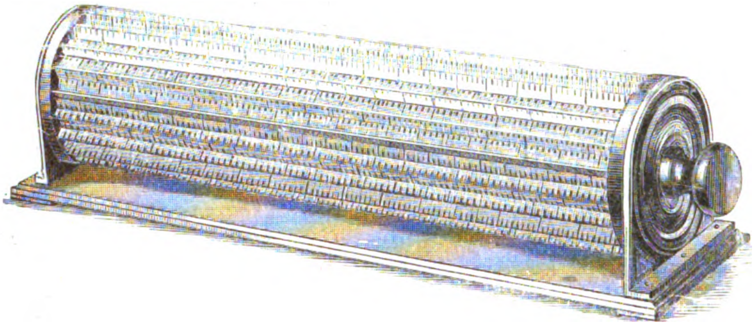


FIG. 1.—THACHER CALCULATING INSTRUMENT.

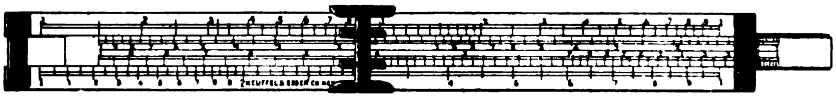

FIG. 2.—DUPLEX SLIDE RULE.

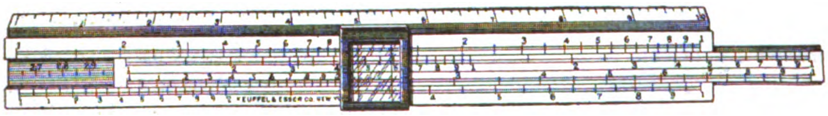

FIG. 3.—MANNHEIM SLIDE RULE.

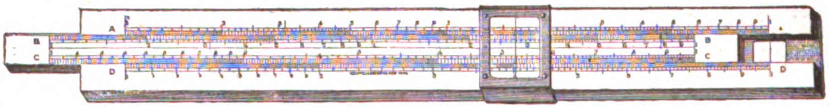

FIG. 4.—STUDENTS' SLIDE RULE.

Besides these they list and carry also the Fuller's slide rule, which has a spiral scale 42 feet long, and the Charpentier and Boucher slide rules, which are disc shaped and intended for the pocket, but are inferior to the straight slide rules. All the above slide rules, except the Fuller, Charpentier, and Boucher, are manufactured by Keuffel & Esser Co. There are listed also slide rules for special purposes, like stadia reductions and sewer computations. Other goods are manufactured in the same or even greater variety, and fully described in the catalogue and carried in stock A visit to their store, 127 Fulton street, woulld be of interest and practical utility to any professional man.

The Montauk Multiphase Cable Adopted by the Gamewell Auxiliary Fire Alarm Co.

THE Montauk Multiphase Cable Co. have originated and developed a new line of cables which, when installed for any or all kinds of interior electric service give to property owners and to insurance companies an additional protection against loss by fire, always sought for, but heretofore unattained. This system gives to wires the power to discover dangerous heat or flame and automatically to notify at any point or points desired that such heat or flame is in existence, and this upon its inception.

The great merit and pronounced value of these cables which have already been described by us, is due to the fact that they are not required to be especially installed for this purpose, but on the contrary, are used in buildings for all of the interior electric work which is at the present time required—therefore, every fractional part of every wire or cable hereafter installed under the Montauk cable system is continuously thermostatic and results in giving protection from loss by fire, although installed for purposes of an entirely different nature.

The property holder is not only benefited by gaining additional protection for life and property, but the insurance companies have an additional guarantee against loss through the use by the public of this system. The value of the endorsement and adoption of the Montauk Multiphase Cable Company's system of interior, automatic, thermostatic, electric cables by the Gamewell Fire Alarm Company, and its auxiliary companies for their specific use will, therefore, be readily understood and appreciated when it is taken into consideration that the Gamewell Co. is the parent of the present extensive fire alarm system which is in use in over 700 of the largest cities of the United States, and has furnished more than 90 per cent. of all the fire alarm apparatus used in the United States and Canada.

It is from their experience of 50 years, or more, of endeavor to give the most reliable and quickest possible notification of fire

in existence that makes such endorsement of the greatest possible value,, for if this company are not experts and capable judges in such matters, there can be none in the United States.

We therefore note with satisfaction these main points brought out in the letter to the Montauk Company, printed below. The statement that "this cable has received full consideration by the Gamewell people," shows that that company has come to the conclusion that an automatic protection can be safely given in connection with their fire alarm system where no other device has ever been relied upon; in other words, they are willing to rely upon the burning of the Montauk cable to close the circuit and thus automatically call out the forces of the fire department through their auxiliary system. Following is the letter:

Montauk Multiphase Cable Co.,
100 Broadway, New York City.

Gentlemen: Herewith we send you formal acceptance of your proposal for furnishing us with your "multiphase electric cables."

After full consideration we have come to the conclusion that we will find, through the use of your cable, something long known to be desirable but hitherto impracticable, viz., a device which we can safely use for the purpose of combining thermostatic fire alarms with our auxiliary system of connection with public fire alarm telegraphs. Yours truly,

GAMEWELL AUXILIARY FIRE ALARM CO.
JOS. W. STOVER, President.

March 30, 1898.

The Jandus Enclosed Alternating Arc Lamp.

A VERY successful alternating enclosed arc lamp of the non-focusing type for circuits of from 7,000 to 16,000 alternations per minute, and voltages from 100 to 120, is being manufactured by the Jandus Electric Company, of Cleveland, Ohio. The design of the lamp, which is shown below, is pleasing and short (thirty inches), and embodies certain characteristics of

JANDUS ALTERNATING ENCLOSED ARC LAMP.

construction that have always been characteristic of the Jandus products, the principal of which are the ring type of clutch, the carbon grip, and the substantial construction in general. The mechanism is so arranged that all joints or pivotal connections between moving members are taut at all times, so that there is no lost motion to take up either in drawing the arc or during the operation of the lamp, and for this reason an absolutely noiseless mechanism is obtained. The solenoids are substantially wound and mounted on vibrating members from which they may be easily removed. A reflecting surface is provided (not shown in the figure), and arranged as a part of the globe cap, which greatly increases the effective illumination, and decreases the heat transmitted to the mechanism from the arc. A reactance (or economy) coil is placed in the canopy of the lamp, easy of access and conveniently adjusted for the voltage of the arc. The efficiency is high, showing a loss of but 20 watts as the lamp is ordinarily adjusted, i. e., 6 amperes on 100 to 110 volt line. The lamp ordinarily consumes from 400 to 450 watts across the terminals, thus showing an average efficiency of 95 per cent. The carbons furnished with lamp consist of an equal number of 1-8 inch core and 1-16 inch core, each 8 inches long. By using the stub of the upper carbon for a lower in the succeeding run, but one fresh carbon per trim is necessary. One 1-8 inch core and one solid carbon give good results. The life of one pair of carbons is about 80 hours.

Lamps for outside service are similar in design to inside lamps, except that they are provided with a weather-proof top, and the finish of the case is a dead black. Inside lamps permit of any finish desired, and are susceptible to highly artistic ornamentation.

Improved Type of the Hatch Storage Battery.

APPRECIATING the wide field now developing in all branches of electrical work for a storage battery of high efficiency, light weight, durability and compactness, the Hatch Storage Battery Company, of Boston, Mass., after long and careful research among those skilled in the art, has secured to itself the exclusive rights to manufacture the improved type of the Hatch Storage Battery, which is described and illustrated below.

In the improved Hatch element, there is no new chemical or electrical principle involved. The invention is of a purely mechanical nature, and relates to the construction of the element, which is practically solid, and integral in all its parts, reducing its weight to the minimum amount of lead oxides necessary to do a given amount of work, and their mechanical support of light material.

An examination of the construction of the cell will show

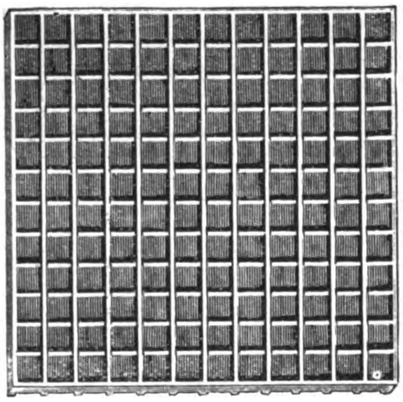

FIG. 1.—POROUS PLATE OF UNGLAZED EARTHENWARE; SQUARED FACE.

how simply and effectually the oxides are locked up in their support, while they are also freely accessible throughout to the electrolyte of the cell. This is also accomplished without any undue compression of the active mass, so that an absolute maximum of porosity throughout is maintained, while the plugs of the active agent are thoroughly exposed on all sides to the electrolyte. The elasticity of the element also provides for a maintenance of this porosity during the charging and discharging processes, which is so essential during any heavy regime of work for the maintaining of potential.

The inventor had in mind the fact that the only materials in a storage battery which actually contribute to the storing of chemical energy, are the metallic oxides and the electrolyte, and to bring these two elements together, with a minimum of mechanical interference, has been his thought and aim.

The electrical efficiency of a storage cell is determined primarily by its internal resistance, and this, in its turn, is governed by the freedom from interference with its chemical and

electrical operation. Purity of material, with a minimum of the mechanical parts, and porosity of the active agent and its mechanical support, to admit of the free distribution of the electrolyte therethrough are the essentials.

The construction of the cell secures all these points perfectly,

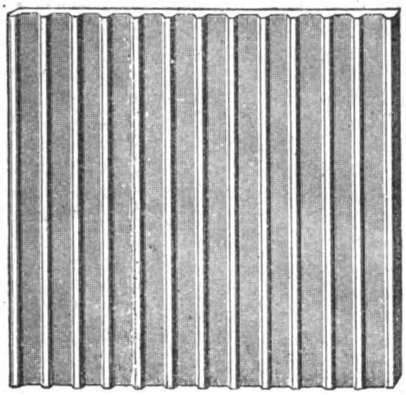

FIG. 2.—POROUS PLATE OF UNGLAZED EARTHENWARE; GROOVED FACE.

and the internal resistance of the 100 ampere hour cell is 25-10000 of an ohm, and other sizes in direct proportion—while the weight of the element to do a given amount of work is reduced fully one-third—as compared with the grid type.

In constructing the element, a porous plate of unglazed earth-

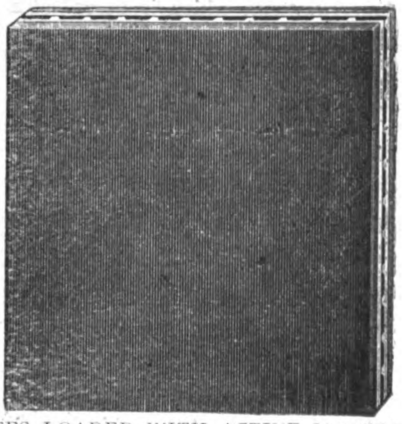

FIG. 3.—PLATES LOADED WITH ACTIVE MATERIAL PLACED TOGETHER.

enware is used with square receptacles on its face side, and grooves on its reverse side as shown in Figs. 1 and 2. To the face side of each plate, the lead oxide or active agent is applied, filling the mass one-eighth of an inch above the surface of the plates, so as to secure an agglomeration with the electrode dur-

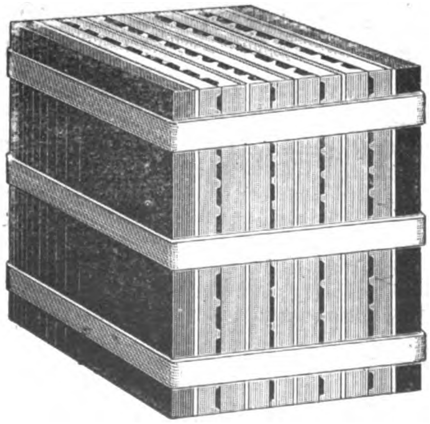

FIG. 4.—ASSEMBLED ELEMENT.

ing the forming process. The plates thus loaded with the active agent are then placed together, back to back, with the grooves crossed, as shown in Fig. 3. This forms one couple, positive and negative, of the element.

A series of these couples are then assembled, as shown in Fig. 4, to form the complete element, as many couples being associated as is necessary for the required capacity.

The sides of this element thus assembled are flanked with a rigid support plate of glass, or similar material, and then en-

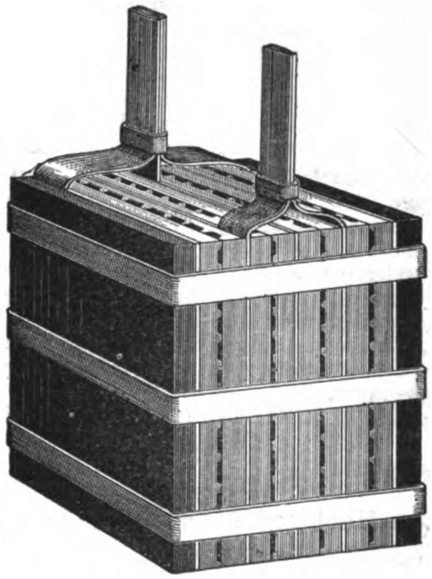

FIG. 5.—COMPLETED ELEMENT WITH ELECTRODES INSERTED.

circled with heavy rubber bands, as shown in Fig. 4. The electrodes are then applied in any desired form, but ordinarily they are applied in the form of lead sheets, interleaved with the active material, as shown in Fig. 5. Reference to this figure as a complete element, will show how permanently the oxides are locked

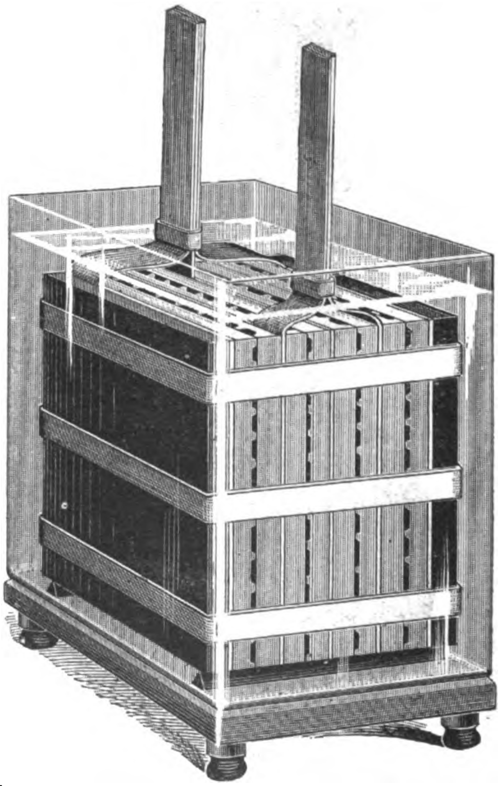

FIG. 6.—THE HATCH STORAGE BATTERY; COMPLETE.

up, while the porosity of the entire mass is secured so that it will remain porous during the work, as the elasticity of the element allows for the expansion and contraction of the active material without closing the pores of its own mass. Provision is also made for free circulation of the electrolyte between the plates, and at the same time allows a free escape of the gases formed by electrolysis.

The battery is splendidly adapted for central station work, as

no amount of current in either direction can possibly injure the element—and the absolute confinement of the active material avoids deterioration by loss of that important agent.

The elements being practically solid, can be used for traction and carriage service without danger of disintegration by jolting, or concussion, and the company are ready to guarantee it for either train lighting, street car work, or any form of carriage service. In all this class of work, the wide variations in output of current called for in climbing grades, rounding curves, etc., make it necessary that the mechanical construction of the element should be adapted particularly for this work. The construction of the Hatch element secures the three desirable qualities: light weight, durability and efficiency.

The company guarantee the maintenance of its accumulators for ten per cent. per annum of their original cost when used for installations for large capacity, like central station work or railway carriage service; provided always, that in such cases, the working of the plants is properly done and within reasonable limits. Such a guarantee makes it absolutely sure to the purchaser that the depreciation will not exceed that of any class of machinery in other lines.

The elements are furnished in plain glass jars as shown in Fig. 6 or in cabinets and portable forms and are built in all sizes ranging in capacity from 5 to 300 ampere hours. They are placed upon the market by The Hatch Storage Battery Company, 53 State street, Boston, Mass., who will gladly furnish estimates and send their illustrated circular to anyone upon application.

NEW YORK NOTES.

WESTERN UNION TELEGRAPH COMPANY has declared its regular quarterly dividend of 1¼ per cent.

ELECTRIC WIRING CO., of Orange, N. J., has been formed, with a capital stock of $150,000, by K. Eppley and W. A. Johnson, of West Orange, and others.

THE LECLANCHE BATTERY COMPANY, 111 East 131st street, New York, report their works busy. They manufacture the well known "Gonda" also the "Vole" open circuit batteries.

AMERICAN SUGAR REFINING CO., of Brooklyn, N. Y., are placing a new fireproof roof over their No. 1 boiler house. The roof will be fireproof, consisting of steel trusses covered with corrugated iron, and is being furnished by The Berlin Iron Bridge Company, of East Berlin, Conn.

COBB-CHAMBERS CO., decorators, 14 Park Place, New York City, have distinguished themselves by their clever work at exhibitions, shows, etc., and are now in line for a large amount of work at the approaching Electrical Exhibition. They issue a tasteful pamphlet illustrated by many pictures of their achievements, large and small, and will be glad to receive and answer inquiries. Orders should be filed at once.

MR. M. A. SINGER, 27 Bond street, New York, who is well and favorably known to many electrical concerns, is preparing a number of tasteful displays for exhibitors at the May show in Madison Square Garden. He will be glad to give information as to prices for fitting up spaces, and for rail, rugs, draperies, carpenter work, etc. His experience in this line will be useful to a great many who need such services.

THE LUNDELL MOTOR seems to be gaining rapid recognition among large power users, owing to the fact, it is stated, that it has never lost in competition with other motors at the hands of engineers, and the further fact that it has given invariable satisfaction during all the years it has been upon the market. One of the latest contracts awarded the Sprague Company is that awarded by the John Stephenson Car Company, of Elizabethport, N. J. Each of the Stephenson machines will have its independent Lundell motor, and the sizes used will be from three to forty horse power, mostly large size machines. Some of them will be direct connected, and some geared. In addition to the power motors, the Sprague Company has secured a contract for exhaust fan outfits. The plant will be one of the largest of its kind in the country, and will employ only Lundell motors.

MR. A. E. WINCHESTER, E. E., of South Norwalk, Conn., was a visitor to New York recently. He is very busy with the details of the extension of his municipal plant. It is understood he will run his lamps at 220 volts.

WESTERN NOTES

EUGENE MUNSELL & CO., importers and wholesale dealers in "Mica," of 117 and 119 Lake street, Chicago, are sending to the trade a blotter, which is rather artistically gotten up and refer to the rapid growth of their business as being the strongest evidence of the superiority of their "Mica." They make a specialty of "Mica" for stove and electrical purposes. A funny little man is illustrated as making quick delivery from a great stock of "Mica" in a great city.

DETROIT, MICH. The Detroit Switchboard and Telephone Construction Company, 330 Lafayette avenue, Detroit, Mich., will be pleased to receive catalogues of metal and woodworking machinery and of electrical supplies of all kinds.

TWELVE WESTINGHOUSE ENGINES will furnish the power for lighting the new steamers being built by the Moran Bros. Company at Seattle, Wash., for service on the Yukon river.

WALKER CO.'S bulletin No. 1070 for April deals with their "converted type" of belted generators, which it describes and illustrates in detail.

THE CITY OF CHICAGO has appropriated $150,000 for the extension of its municipal lighting system. Ten 150 light arc machines of the Western Electric Company's manufacture have been ordered by the city.

TOLEDO, O. Messrs. J. Scott and Bert Christian have formed a partnership for electrical construction under the name of Scott & Christian, with offices in the Valentine Building. They are well known, and already have several nice contracts.

CENTRAL ELECTRIC CO. Chicago, are carrying in stock Edison fuse plugs of all sizes, standard fuse wire put up in neat and attractive packages convenient for use, fuse links with copper terminals of all lengths and capacities, as well as a full assortment of fuse strips. The composition entering into their various fuse material is the result of numerous experiments, and practical tests have determined its value.

USERS of miniature incandescent lamps appreciate the advantage of having a miniature lamp of standard make that can be depended upon for efficiency and length of life. The Packard sign lamp, which is a miniature lamp about 2 inches long over all and 1 inch in diameter, fills the demand for a high grade miniature lamp. It is mounted with regular Edison candelabra base, gives about two candle power and burns 4 in series on 50 to 60 volts or 8 in series on 100 to 120 volts. This lamp is carried in stock in Chicago in large quantities by the Electric Appliance Company, who always hold themselves in readiness to ship promptly any number of these lamps and the necessary sockets.

NEWGARD WATER PROOF RECEPTACLE AND GLOBE, recently patented, is finding a large field of usefulness in breweries, paper mills, packing houses, sugar refineries, and all other places where moisture or fumes make the insulation of an ordinary lamp socket a difficult proposition. The price of this device is down to a point where it is economy to use it in all places where high insulation is required. The Newgard receptacle and globe is so simple in construction and yet so clever in its conception that it commends itself to every one at first sight. The Electric Appliance Company are always glad to submit a sample of this globe where there is a possibility of their adoption.

NATIONAL CYCLE MFG. CO., Bay City, Mich., H. B. Smith, president, have issued some good literature with regard to their excellent wheels, which have many special features in chain adjustment, seat post, handle bars, detachable sprockets, crank hanger brackets, forged arched fork crown, etc. Frames are made 22, 24 or 26 inches in height, and three colors are used in decoration. The tires are the best on the market, saddles are Sager or Gilliam. Mr. Smith is well known in electrical circles as the secretary and treasurer of the Michigan Pipe Co.

HARTFORD, CONN. The Hartford City Gas Light Company has placed another contract with the Berlin Iron Bridge Company of East Berlin, Conn., for one of their steel roofs with patent anti-condensation fireproof roof lining, which has given the Gas Light Company much satisfaction in the past. The new building is about 35 feet wide and 70 feet long, having brick sides and iron roof constructed as mentioned above.

ADVERTISERS' HINTS

SPRAGUE ELECTRIC CO., 20 Broad street, New York, are advertising a fan outfit for suspension from a ceiling. The fan bades and guard may be turned in any direction.

THE COULTER & McKENZIE MACHINE CO., Bridgeport, Conn., manufacture cross arm braces, plain or galvanized, for telephone and electric light work, also feeder brackets for trolley wires.

THE COBB-CHAMBERS CO., 14 Park Place, New York, take entire charge of designing, building and decorating exhibits.

C. S. KNOWLES, 7 Arch street, Boston, Mass., says that danger from grounding or short circuit is entirely eliminated by the use of the "Erickson" outlet insulators. They are made in a durable form, have a threaded metal member to receive the conduit pipe, and the outer end is enveloped by high grade insulating material.

THE STANDARD TELEPHONE AND ELECTRIC CO., Madison, Wis., claim a record of having installed 50,000 instruments, in use in 400 exchanges and all doing satisfactory work.

BOOTHS FOR THE ELECTRICAL SHOW may be ordered from M. A. Singer, 27 Bond street, New York. Estimates and sketches will be sent on request.

THE WAGNER ELECTRIC MFG. CO., St. Louis, Mo., are building single-phase, self-starting alternating current motors, which are said to be a success in every respect.

THE C & C ELECTRIC CO. have changed their Boston office to 19 High street.

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, Ill., advertise the "Packard" sign lamp, a miniature lamp burning four in series on fifty volts or eight in series on one hundred ten volts. They claim high efficiency and long life for them.

THE GARTON-DANIELS ELECTRIC CO., Keokuk, Iowa, have had a great increase in the sale of their lightning arresters. Their January and February business for 1898 was over 300 per cent. greater than for those months last year.

WESTINGHOUSE, CHURCH, KERR & CO. as engineers and Westinghouse Machine Company, as manufacturers, represent a most excellent combination of engineering experience and manufacturing facilities, which should guarantee the most excellent service to those interested in the generation of power—steam, gas or electric.

THE WESTINGHOUSE ELECTRIC & MFG. CO., Pittsburg, are ready with their 1898 models of electric fans.

THE WALLACE BARNES CO., Bristol, Conn., advertise springs of every description, and a large assortment of cold rolled steel.

THE ELECTRICAL EXCHANGE, 166-174 South Clinton street, Chicago, present a revised list of bargains in electrical machinery, lamps, instruments, supplies, etc.

A. L. IDE & SONS, Springfield, Ill., publish a decision recently awarded them on patent rights.

CENTRAL ELECTRIC CO., 173-175 Adams street, Chicago, advertise new prices on wire, line material and tools.

THE MONARCH MFG. CO., 39 Cortlandt street, New York, are introducing the "Monarch" engine stop and speed limit. This device is to an engine what a safety valve is to a boiler. It is designed to close the throttle when a predetermined speed is reached.

G. M. ANGIER & CO., 64 Federal street, Boston, Mass., have something to say about their long-burning series arc lamp.

THE JANDUS ELECTRIC CO., Cleveland, Ohio, say that 25 single carbons at the trivial cost of 75 cents is all that the Jandus lamp will consume in one year. Their new catalogue is now ready and describes the different varieties of the "Jandus" for all classes of service.

THE PHOENIX CARBON MFG. CO., St. Louis, Mo., claim that the interlocking device of the Phoenix batteries stands at the head, and they mention many other strong points in its favor.

THE PENNSYLVANIA RAILROAD has ordered for its Altoona shops two 160 h. p. tandem compound engines, arranged for direct connection to 100 kilowatt dynamos. The engines are furnished by the Ball Engine Co., Erie, Pa., and dynamos by the General Electric Co.

FOREIGN NOTES

WALKER, BAILEY & CO., of Buenos Ayres, Argentine Republic, are now installing the first outfit of electric motors for supplying all of the motive power in a factory, that has ever been installed in that country. The plant is for a weaving factory, and is to be driven by Lundell electric motors of such power that each motor will drive six machines. There are instances where it is advisable when putting in electric motors, to fit each machine with a separate motor, but in this instance the machines are always in operation.

WESTINGHOUSE ELEC. AND MFG. CO. has just opened a new branch office at Austin, Texas. Mr. J. E. Johnson will have charge of the office and of the further extension of Westinghouse business in the Southwest. The large contracts which this company has been handling in Mexico and the Texas region have compelled the establishment of this new centre of electrical trade.

TELEPHONY AND TELEGRAPHY

The New Bell Telephone Plant in St. Louis, Mo.

BY FRED E. BAUSCH, E.E.

Distributing Head.

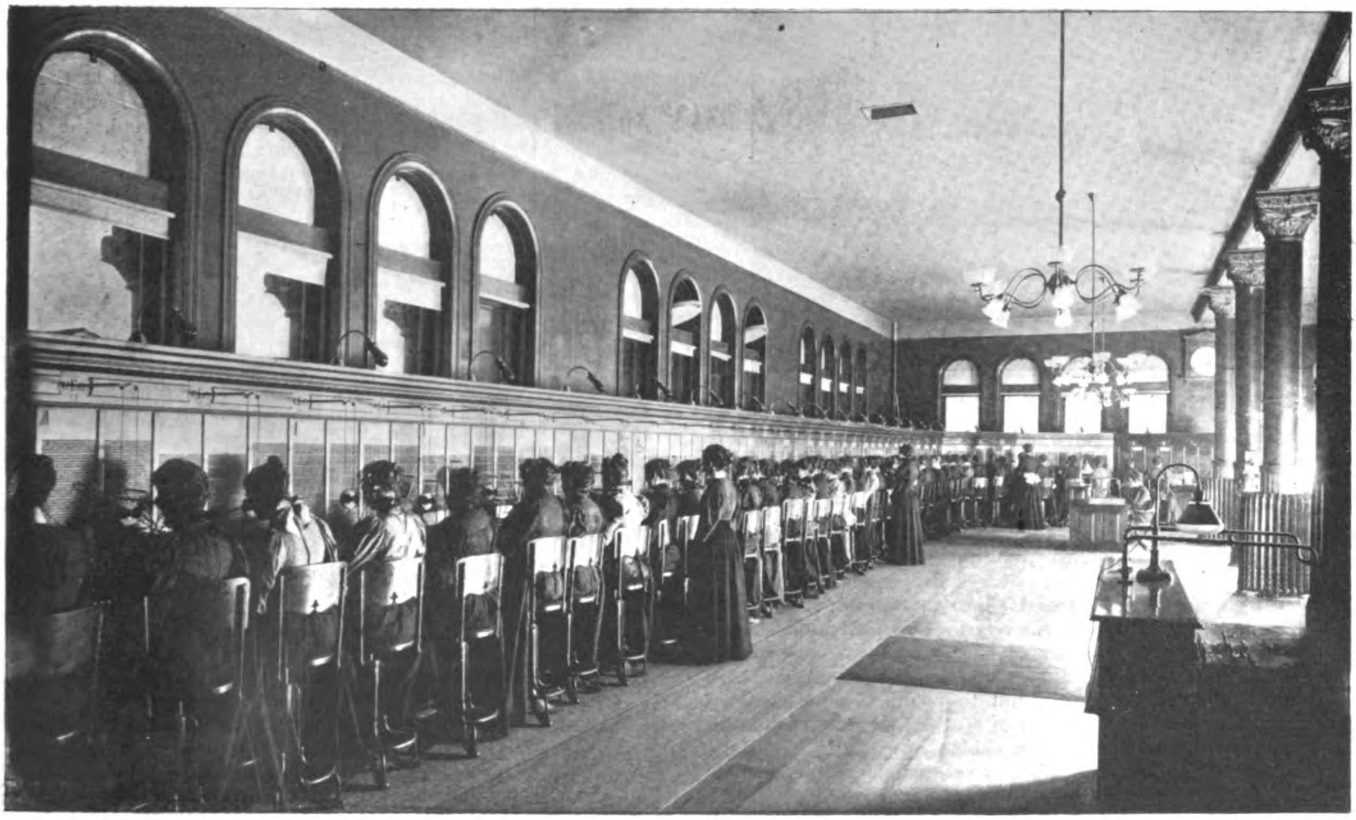
THE development of the art of telephony ranks preëminent amongst enterprises associated with electrical progress. From the day of the first public exhibition of the transmission of speech over wires, at the Centennial in 1876, to the present day, of the mammoth telephone switchboards where tens of thousands of wants are satisfied daily, and distance is robbed of its true meaning, the evolution of the telephone industry and its stupendous growth is indeed significant. Since the inception of the telephone it has been the persistent aim in the telephone business to maintain the highest standard of efficiency, and meet the increasing demands on the system most expeditiously, to which end it has involved unlimited capital, brains, and the untiring efforts of thousands engaged in the work.

The 22d of April marks the twentieth anniversary of the existence of the Bell Telephone Company of Missouri, operating in St. Louis, in connection with an extensive network of toll line system throughout the State of Missouri and parts of Illinois. The original exchange, then established at 417 Olive street, and opened with a patronage of four subscribers, was based on the magneto system. The receiver and transmitter for all practical purposes were alike and correspond in construction to the present form of receiver. The Blake transmitter had yet to be invented, and with it was introduced a form of battery transmission.

The Law system of horizontal multiple switchboard with local battery was subsequently adopted. In later years the installation was supplemented by the Dean common battery system, an invention of the company's former electrician, and metallic service for local and long distance transmission.

With the natural expansion of the business of the various wire using companies, St. Louis was one of the first cities to appreciate the benefits of underground service. Its telephone company long since urged permission to bury its wires, but was hampered by municipal legislation, until the appointment of a Subway Commission by the Mayor in November, 1893. After a systematic study of the experiences of other large cities in this country and abroad, followed by dilatory legislation, an ordinance was adopted on Sept. 8, 1896, and is the one now in vogue, regulating the construction and operation of underground conduits in St. Louis. The ordinance, in brief, provides that no wires, tubes or cables, conducting or transmitting electricity, shall be placed above the surface of the street, alley or public place in the district of the city bounded on the east by the Mississippi River, on the west by the west line of 22d street, on the north by the north line of Wash street, and on the south by the south line of Spruce street, and its prolongation to the west line of 22d street after Dec. 31, 1898, except those necessary for connections for local distribution. The ordinance further provides that poles may be placed in the alleys for purposes of distribution, provided plans have been approved and permits have been issued by the Board of Public Improvements.

On April 19, 1897, ground was first broken preparatory to the construction of the conduit system of the Bell Telephone Company of Missouri. After an interval of precisely four months, on August 17, cable was drawn in through the ducts, and by the last of the year an underground system was perfected, of an order, and in an expeditious manner, the like of which has been rarely before attempted.

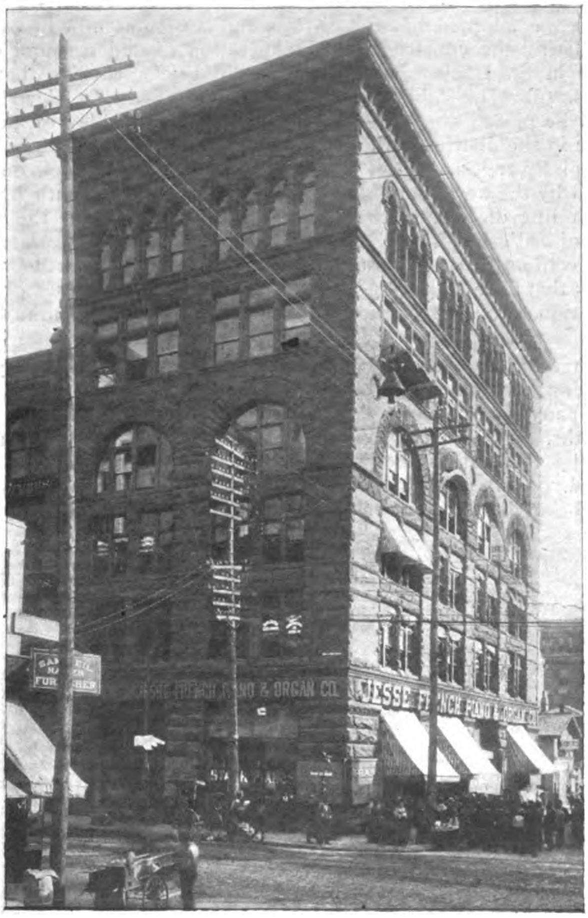


NEW TELEPHONE EXCHANGE OF THE BELL TELEPHONE COMPANY OF MISSOURI.

A reference to the accompanying map of the underground district clearly indicates the plan of distribution adopted by the

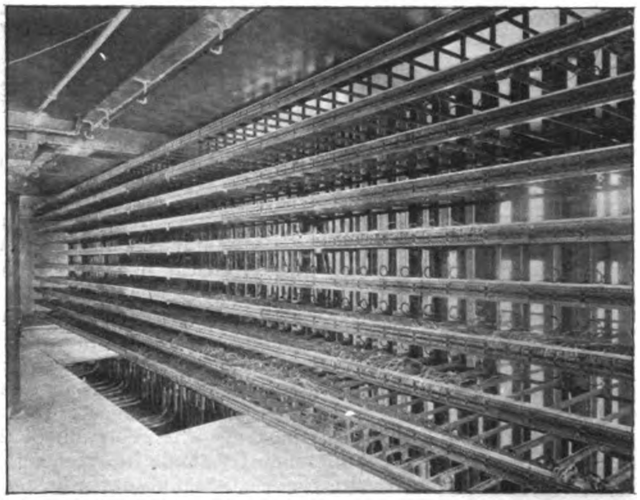
Bell TelephoneCompany of Missouri. The three backbones run east and west on Olive street, north and south on 10th and 4th streets. Tributary to these are mains running north and south or east and west as the requirements demand, and in turn led off from these are the various distributing lines which run in the alleys and are tapped at intervals through laterals, to supply office buildings, by cable containing a number of circuits or distributed to individual subscribers by single pair cable. (See page 422.)

Twelfth street divides the subway territory into east and west districts. In the latter, terminal poles are located at the entrance to alleys intersecting the streets, carrying the runs. The cables on leaving the manholes are led through three inch iron pipes to the terminal poles and terminate in a cable head. The various circuits are from here distributed by short overhead lines to the telephone subscribers. East of 12th street, which is the business district of the city, the underground construction has been rigidly adopted. As before, manholes are located at the entrance of alleys, but in place of erection of an alley pole line,



TELEPHONE BUILDING, 10TH AND OLIVE STS., ST. LOUIS, MO.

a distributing duct entering the street manhole is run along the alley, having a manhole in its centre and one at the end where the duct is dead ended. The cable-head is located in the manhole in the centre of the alley, and distribution effected from this point. Along the distributing duct, at intervals determined with reference to the requirements, junction sections are inserted, from which the single pair lead covered cables are led through three inch iron pipe (called laterals) into the basement or cellar of building in which the subscriber is located. In office buildings containing a large number of subscribers, an entire cable enters the basement and terminates in a large cable-head where each wire is separately brought out to terminal posts. From these the circuits issue in the form of a cable, which on reaching the various floors, is spliced with cables of smaller units, the latter terminating in smaller cable boxes, from which the final circuit to the subscriber's instrument is completed. This arrangement permits of changes such as are likely to arise through the new location of subscribers or for other reasons. The distribution tile (known as the Johnston duct, from the name of the inventor, who has immediate supervision of the subway construction) is unique. The tile, made in two-foot lengths, consists of two through ducts for single pair cables, one enclosed cable duct and a shallow channel above the same, permitting a device used for drawing in the single pairs. The junction sections are

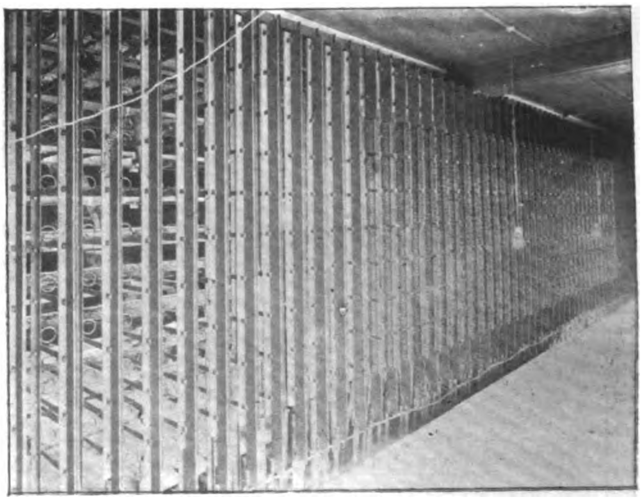


MAIN DISTRIBUTING BOARD, HORIZONTAL SIDE.

identical with the distributing tile, excepting a three-inch side opening for lateral connections.

All the main runs, with few exceptions, consist of 3¾-inch hollow brick tile 18 inches long, of octagonal exterior, made of sewer pipe clay, glazed inside and out, and manufactured by the local firm of Evens & Howard. The short lengths of tile proved to be a very flexible means of conduit construction, as it was comparatively simple to evade obstructions or adapt the course of conduit to unfavorable conditions, frequently encountered. This pipe was laid 5½ inches between centres, the intervening space being filled in with cement mortar. The successive rows were separated vertically by a ½-inch layer. Joints were made abutting, encased by mortar, one part cement to two parts sand, and broken horizontally and vertically. A mandril was drawn through the ducts as the work progressed to preserve the alignment and prevent the mortar from entering the duct. The mandril consists of a cylindrical piece of wood, three feet long, large enough to clear the duct, with washer attached at the inner end, and a hook for withdrawing it at the outer end.

All cement used was the best American Portland, the concrete foundation for the conduit ranging from four to six inches, according to the layers of duct. The sides and top of conduit were encased by three to four inches of concrete mixed in the



MAIN DISTRIBUTING BOARD.—VERTICAL SIDE.

proportion of one part cement, three parts sand and six parts broken stone.

A notable instance of the ease with which difficulties were surmounted with this form of tile is that shown in the view, illustrating the "fanning out" of two layers of tile into a single layer,

necessary because of the very shallow depth allowable for the conduit over the 8th street tunnel. In several localities where obstructions consisted of a network of interfering gas and water pipes, iron pipes were resorted to and bent into shapes best adapted to conditions.

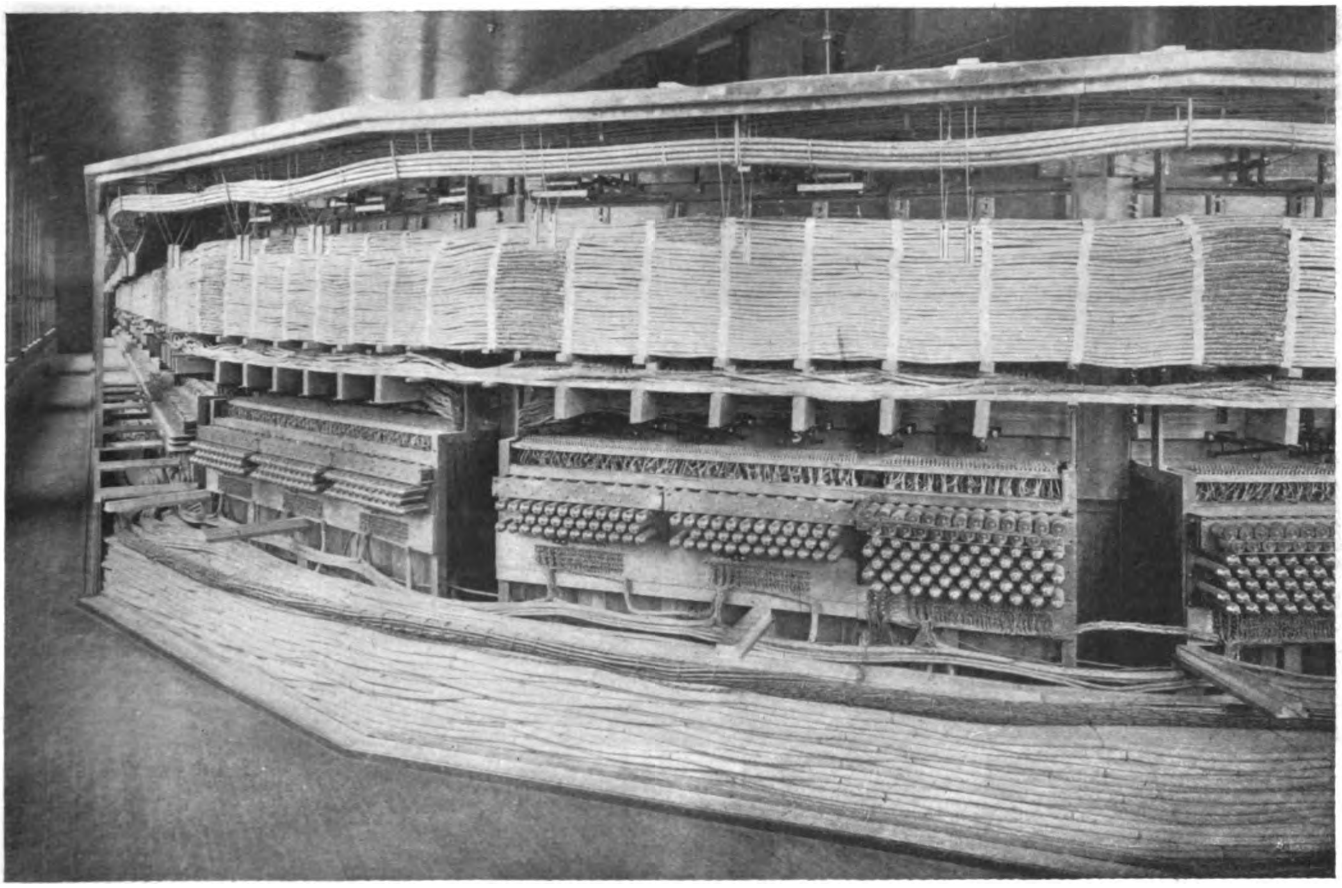
The multiple duct, of which but a short run was installed, was in the nature of an experiment. It consists of four rectangular compartments, 3¾ inches wide by 4 inches high, with 1-inch walls. It is made in two-foot lengths and intended only for places where multiples of four ducts were used, since the roof of one layer is formed by the bottom of the next layer above, which has grooves on the lower surface to fit in tongues formed by the walls of the layer beneath. The last layer above is covered by an arched sheet of mild steel, No. 22 gauge, and bent to lap over the sides. As in laying other styles of conduit, the sides and top are encased in concrete, the foundations and general work being identical. This type of duct was laid with remarkable rapidity, about 2,000 feet being placed by one pipe layer and helper a day.

Approximately, the Bell Telephone Co.'s conduit consists of

The Telephone Company enjoys the distinction of having outdistanced all other wire using companies in the city, in point of time of completion of its underground work.

A method, thoroughly practical and effective of results was that adopted for pulling in the large 120 pair cables used in the street conduits. It consisted in using steam in place of the old turn-stile method as motive power for drawing the cables through the ducts. A small 3½ h. p. horizontal engine and capstan was mounted on a low wagon. Through suitable gear attachment the capstan was made to revolve and wind up a rope, one end of which was manipulated by a man and the other end securely fastened to the cable to be drawn through. The accompanying sketch illustrates the relative positions of cable reel, engine, capstan, and two manholes. In this manner, a speed of 25 feet of cable per minute was easily attained. The rapidity of execution of the work was in part due to this contrivance.

Simultaneous with the outdoor construction, a very active condition of affairs prevailed in the various other departments of the Telephone Company. Plans were drawn up and negotiations entered into with the Western Electric Company of Chicago, for



REAR OF MAIN SWITCHBOARD.

600,000 feet of cable capacity. The general size of manhole is 5 feet by 5 feet by 5 feet with 9-inch brick walls, concrete bottoms, 6-inch clay tile sewer with ¾-S iron trap, and covers grated where necessary. The roof is 10 inches concrete, with rectangular opening for 24-inch by 30-inch self-locking cast steel cover, either solid or ventilated pattern, provided with dirt pans beneath. A number of concrete manholes were also used west of 17th street. The total number of manholes is approximately 600. The largest of these is the main vault under the street on the west side of the Telephone Building. Here on the north and south walls terminate the conduits from the four ends of the city, the south wall containing the 25 ducts of the main line running south, while the runs leading east, north and west, with a total of 86 ducts, are in three sets of ducts, four ducts to the layer, each set completely encased in concrete and separated by one foot of concrete from the adjoining one. The main vault is 12½ feet by 24 feet by 8 feet, with 17-inch brick walls, a 1-inch air space being left on the inside course to render the manhole moisture proof. The roof is 17 inches concrete, supported by 12-inch steel I-beams.

a colossal switchboard of the common battery, multiple branch terminal type, for the new main exchange. On the 15th of November the switchboard arrived, and immediately the work of "wiring up" was begun. Through skilful executive management all of the 4,000 subscribers' positions were completely wired in every detail in the remarkably brief time of two months, for on the 16th of January, at 2 a. m., the first public message was sent through the exchange, thus inaugurating the new metallic system and making the underground telephone service in St. Louis an undisputed reality.

The entire six-story building at the southeast corner of 10th and Olive streets, with the exception of the ground floor and an office on the second floor is given up to the various departments and new main exchange of the Bell Telephone Company of Missouri.

Entering the main vault are forty-two 120-pair lead covered cables, supported on vertical standards, with brackets suitably arranged for curving the heavy cables into the basement on their run to the cable shaft. At the entrance to the shaft they are corniced up and take a vertical course to the fourth floor, ter-

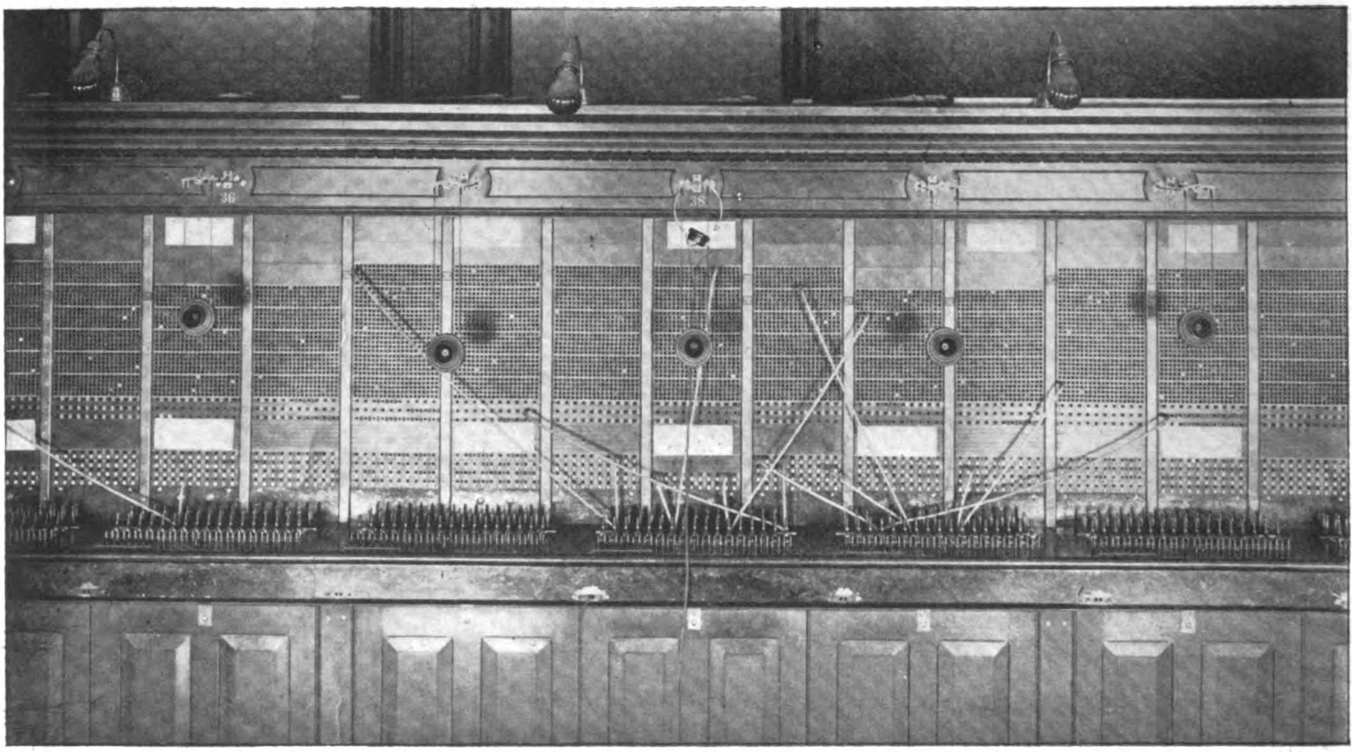
minating on the horizontal side of the main distributing frame. As shown by the view of this side of the board, the 240 wires in each of the 42 cables are "fanned out" and soldered to clips arranged horizontally, along the board, and numbered for convenience, with respect to the cable to which they belong. On the opposite side the main distributing frame is arranged in vertical strips and each subscriber located according to the number assigned to him at the operators' switchboard. Connecting the horizontal with the vertical side are the cross-connecting wires, called "jumpers."

A very important feature of the main distributing board is the precautionary means adopted for protection against the action of lightning and high tension currents due to a cross on the line. The device employed to protect the operator and the switchboard apparatus against the effect of lightning, consists of two carbon plates insulated from each other by a fine strip of mica, one of the plates containing a small cavity filled with fusible metal and grounded. The instant a flash of lightning passes over the wires the arc jumps across the plates and passes to ground through the grounded carbon, thus diverting the course of danger from the switchboard. The sneak current protector, intended for cases of accidental cross on a subscriber's line, with an electric lighting or power circuit, consists of a small coil of German silver wire wound on a hollow brass spool. A short metal rod passes through the hole in the spool and is held in place by a drop of fusible alloy, the whole mounted in a small fibre case. This contrivance is supported between two springs. When a current of abnormal strength flows through the circuit, the wire on heating the spool melts the metal, and releasing the pin, grounds the line, thereby opening up the line in the exchange. In this way danger is averted which might otherwise cause havoc in the exchange. If the cross remains on, the fuse at the cable terminal is blown and prevents damage to the cable itself.

At the main distributing board all changes are made due to the removal of instruments, changes in location of subscribers and new connections. From the vertical side of the frame the wires pass in cables to the intermediate distributing frame located on the sixth floor. In appearance, this frame is very similar to the one on the fourth floor, with the exception that the protection devices previously referred to, are missing. As its name implies, this frame serves an intermediary connection between the main frame and the swithcboard. Its office is to permit of a rearrangement of lines to any operator's position for the purpose of equalizing the calls received over her lines. In this way it is a simple matter at any time to balance the amount of work shared by the operators. This is naturally of prime importance, as it minimizes the time required for connection between subscribers.

From the horizontal side of the intermediate board the wires pass to the multiple jacks and at this point are also connected by jumper wires with the vertical side, to the answering jacks, line and cut-off relays.

The main switchboard, which embodies principles and improvements of the most modern and advanced type, consists of 19 sections, with three operators' positions at each section. Finished in mahogany, it stands about six feet high, four feet wide, and presents an overall length of nearly 115 feet. Its construction is based on the multiple, common battery, branch terminal, metallic system. It is at present wired for 4,000 subscribers' circuits, and is capable of accommodating an ultimate capacity of 5,600 circuits. Two and one-third sections are reserved for incoming trunks from the various branch exchanges, located in the different districts of the city. One section, at the north end of the board, is set aside for all message-rate subscribers, whose calls are recorded and their quarterly rates determined accordingly.



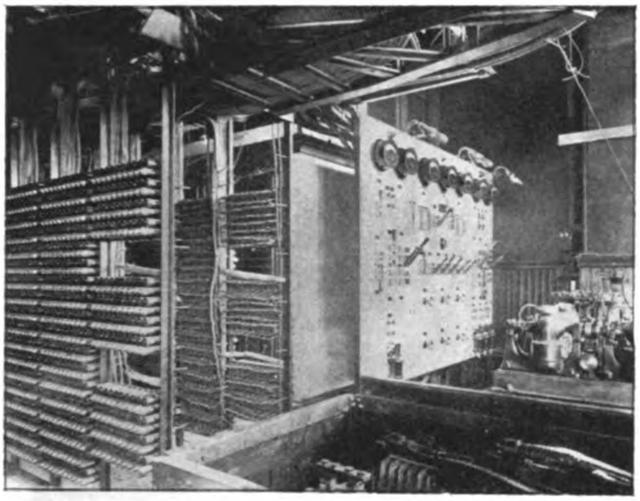
SECTION OF SWITCHBOARD, SHOWING CONNECTIONS SET UP.

As implied by the term "multiple," all the subscribers' lines are multipled in each of the sections of the board. Each operator, although occupying one-third of a section, has a third of a section to the left and a third to the right at her disposal; in this manner having within reach one complete section. As all the subscribers' lines terminate in every section, each operator can readily complete a connection without transferring to another operator.

In addition to the 4,000 calling jacks, there are on the lower tier of the switchboard, as illustrated in the view, 260 answering jacks, appearing only in that particular section and representing the set of subscribers' lines over which the three operators receive their calls.

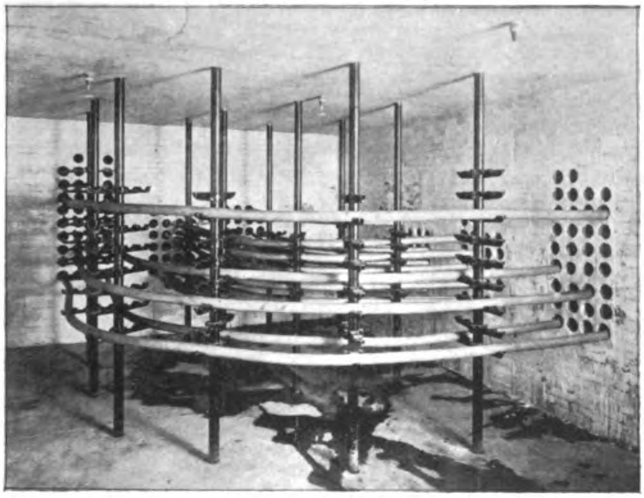
The most novel and striking feature of the switchboard is the automatic arrangement for signalling the operator when a connection is desired. The device consists in the use of miniature electric lamps controlled by relays and suitable resistances, and placed directly beneath the spring jack corresponding to a calling subscriber. Upon the glow of such lights and a larger pilot lamp in front of the operator to attract attention, it is at once known what subscriber has removed his telephone from the hook and desires a connection. On a horizontal keyboard below the jacks just referred to, is a double row of plugs at the ope-

rator's command, the rear set intended for insertion into the answering jacks, the front set being only used to connect with the calling jacks. Corresponding and connected with the two sets of plugs are a double row of miniature cord lamps, whose office is to indicate when the parties have ended their conversation. The keyboard is so constructed as to admit of party



RELAYS, GENERATORS AND POWER SWITCHBOARD.

line service, where two subscribers are connected on the same circuit, one subscriber's signalling apparatus on each side. Each operator's position is equipped with ringing and listening keys corresponding to the plugs at her command. In addition to the possibility of reaching every subscriber in the exchange, each operator is provided with facilities for connecting with branch exchange subscribers over trunk lines. The operation of completing a connection is comparatively simple. A subscriber, on removing his telephone from the hook, preparatory to calling up another subscriber, indicates this fact by the simultaneous glow of the lamp corresponding to his line in the exchange. The operator immediately inserts an answering plug in the jack above the lamp, thus extinguishing it, and on throwing over the listening key opposite the plug, communicates with the subscriber and inquires "what number" is desired. Upon receipt of this, the operator touches the ring of the jack with



MAIN VAULT.—LOOKING NORTH, SHOWING 85 DUCTS.

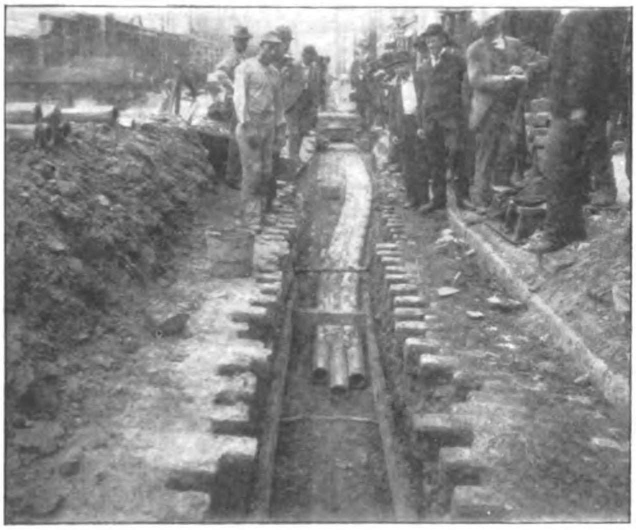
the tip of the calling plug, and if the line is busy it is indicated by a click in the operator's head telephone, but if clear no click is received and a calling plug is inserted into the multiple jack of the designated number and the called subscriber signalled by ringing his bell with the proper ringing key. When conversation between subscribers has ended and the receivers are replaced on the hooks, the little miniature lamps connected with the cords of the corresponding plugs, and which have been dark during the conversation, now flare up, indicating the disconnect signal to the operator. In general, while the lines are connected, it is evident that when the receivers are off the hook the cord lamps are dark, and when replaced the lamps are bright. The large pilot lamp before each operator, and which simultaneously responds with the small lamps below the answering jacks, when a call is received, are duplicated on the chief operator's tables. In this manner, it is possible to know the exact condition of affairs at any operator's position on the entire board. By observing the various lamps at her board, the chief operator can tell at a glance how promptly calls are being answered and how busy any section or the entire board may be, at any instant.

A toll board, for the outlying stations in Missouri and Illi-

SIX LAYERS HOLLOW BRICK TILE ENTERING MANHOLE.

nois connected with the system, is another adjunct to the switchboard equipment. On the fourth floor the wire chief's table plays an important part in the working of the Exchange. For it is here that all the subscribers circuits are systematically tested at regular intervals, complaints registered and orders issued for immediate repairs.

The back of the main switchboard, as illustrated in the cut, presents a fair idea of the magnitude of wiring required to complete the circuits of the lines entering the main office. Contrary to off-hand impression, it is a notable fact that the cost per subscriber's position increases with the increase in the number of subscribers in an exchange, owing to the additional number of times the line must be multipled throughout the board in order to appear before each operator. It may be possible to

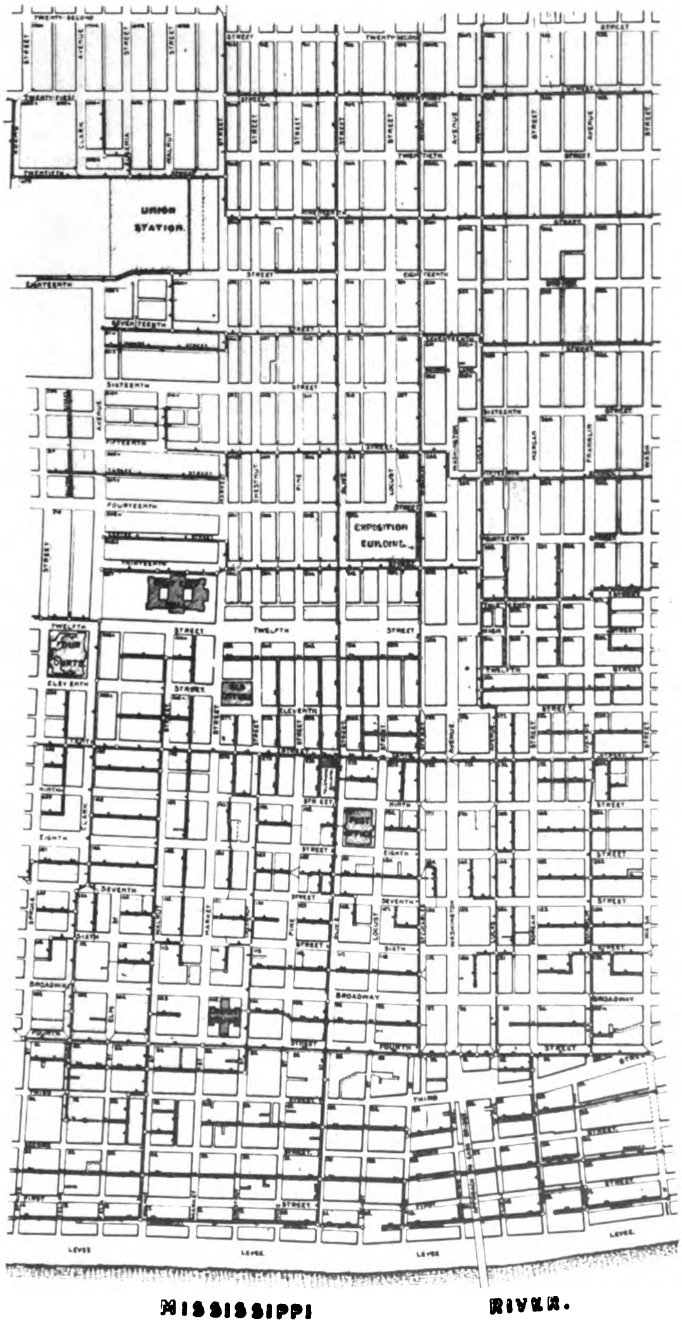


HOLLOW BRICK TILE, TWO LAYERS "FANNED OUT" TO MAKE ONE OVER EIGHTH STREET TUNNEL.

realize the outlay of wire required in the installation of such an exchange, when it is stated that there are five million six thousand feet of wire in the straightaway cables, and nine million two hundred and eighteen thousand feet of wires in the

relays and other coils. The number of soldered connections between the terminals of cables on the main distributing board and the operators' switchboard is estimated to be at least one-half million.

Most of the 120 pair cable used in the conduits was furnished by the Standard Underground Cable Company of Pittsburg, and the remainder by the Western Electric Company of Chicago. The 240 conductors are of hard drawn copper, No. 19 B. & S. gauge, paper insulated and twisted in pairs, the whole encased in a heavy lead sheath. Before acceptance, each cable was tested for capacity not to exceed .08 microfarads per mile,

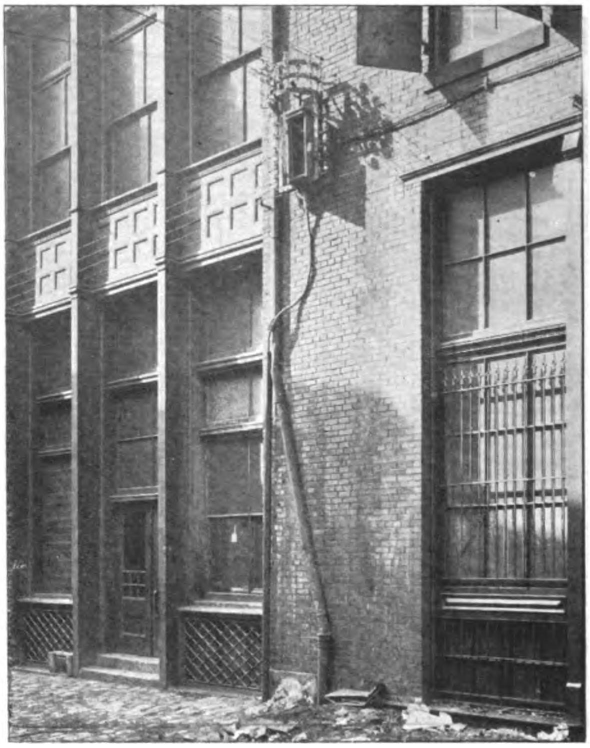


MAP OF UNDERGROUND DISTRICT, ST. LOUIS, MO.

and the insulation resistance not to fall below 500 megohms per mile.

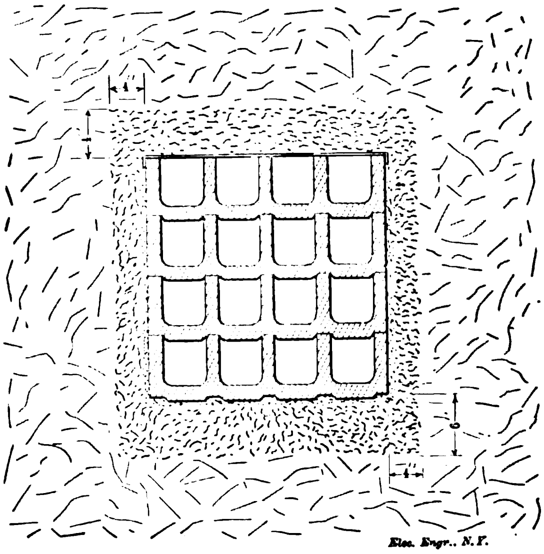
All single pair lead covered cable, furnished by the American Electrical Works of Providence, Rhode Island, was of No. 20 B. & S. gauge, with double cotton insulation and twisted. All of this cable was tested for insulation with a pressure of 2,000 volts and an insulation resistance not to fall below 250 megohms per mile.

Contrary to the Law system, where the local batteries are required at the subscribers' instruments, thus necessitating a great deal of inspection and renewal, the most modern and simplified form of battery transmission concentrates the electrical energy at a central point for distribution. In the battery room, which is the heart and lungs of the telephone exchange, large sets of storage batteries are installed. Eight large cells of style



CABLE BOX IN ALLEY.—UNDERGROUND CABLE TERMINATION AND DISTRIBUTION OF CIRCUITS OVERHEAD.

31-G Chloride Accumulator, feed the miniature 8-volt cord signal lamps. While one set of four cells is being discharged the other set of four is being charged from the motor generators. The normal useful capacity of these cells is 3,000 ampere hours. Ten cells of 11-G type are used for talking current over the lines.

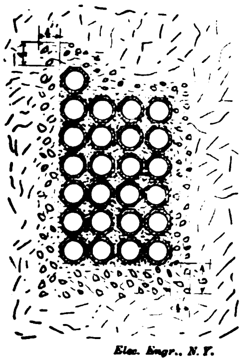


MULTIPLE DUCT TILE CONDUIT.

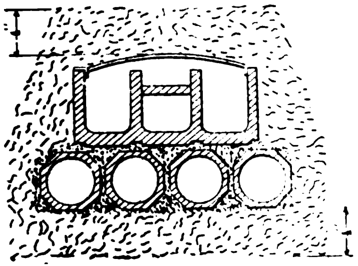
They are charged at the rate of 50 amperes and 24 volts. The discharge is at 20 volts, while the current necessarily varies, ranging from 10 to 50 amps. In addition to these, there is a set of six cells of style 11-F to supply current for the transmitters and line signals.

In the power room adjoining, are the motor generators, including the ringing and "busy" signal machines manufactured by the Western Electric Company. Current for ringing and

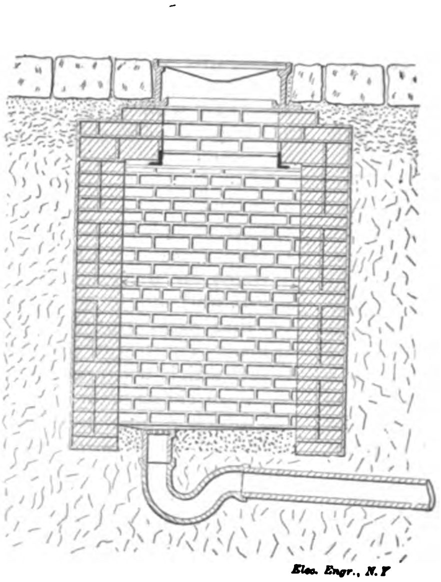
signalling is furnished from the same machine. The ringing current is supplied from the alternating side of the generator, while an ingenious device is attached and produces a note of high pitch, which, by a system of gearing, is interrupted at regular intervals, so that when the operator inserts the answer-

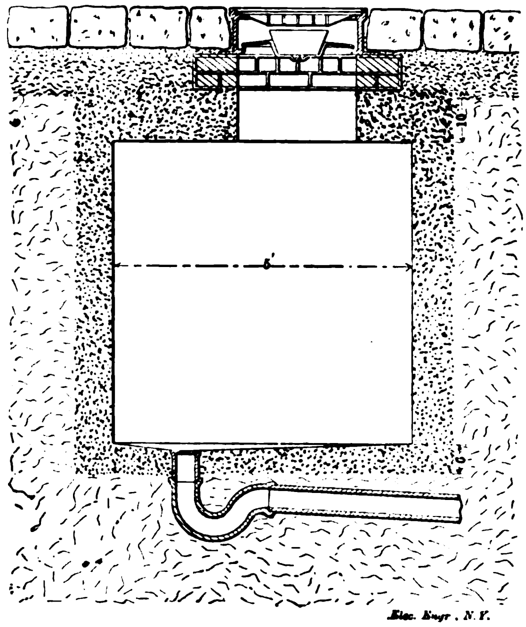


3¾-INCH HOLLOW BRICK TILE CONDUIT.



DISTRIBUTING DUCT TILE CONDUIT LAID ON HOLLOW BRICK TILE.



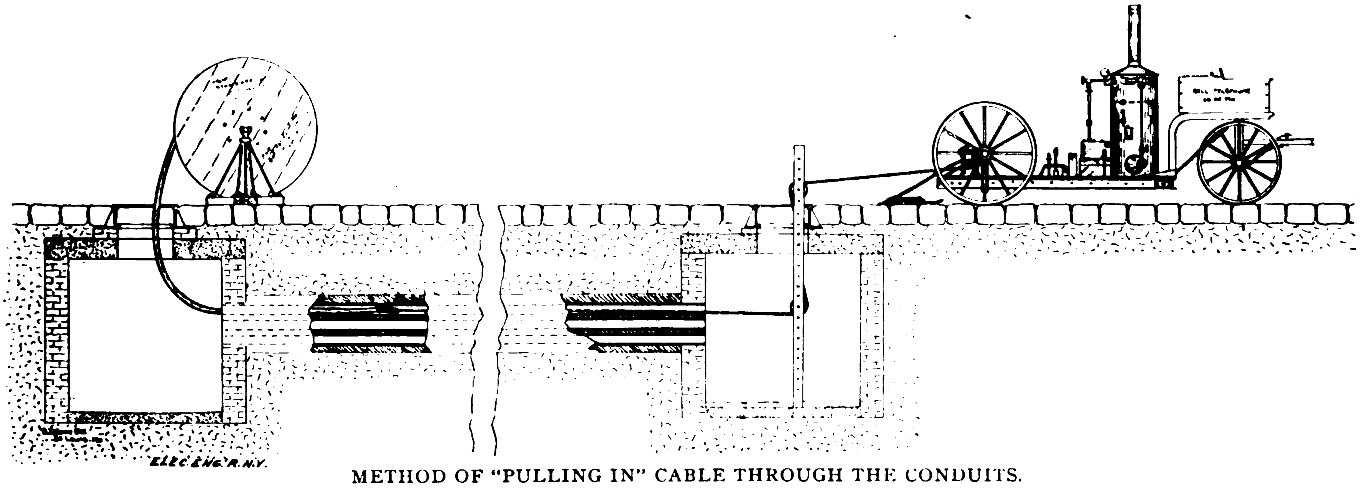


TYPICAL FORMS OF MANHOLE CONSTRUCTION.

ing plug into special jacks, reserved for the purpose, a series of interrupted "toots" is transmitted to the subscriber, indicating that the line desired is busy.

Located in a convenient position, the power switchboard, of polished white marble, is equipped with the necessary switches for charging and discharging the batteries, in addition to a complete set of volt meters, ammeters and fuses, all of Western Electric construction.

During the day, current for the motor generators, which charge the batteries, is furnished by the local plant in the basement of the building. This consists of a 10 h. p. horizontal Ball engine, direct connected to a direct current machine, capable of an output of 50 amperes at 220 volts. At night or in cases of emergency, current is tapped from the mains of the Missouri Edison Electric Company or received over a feeder directly connected with the local plant of the branch exchange



METHOD OF "PULLING IN" CABLE THROUGH THE CONDUITS.

in South St. Louis. The motor generators receive the current at a pressure of 220 volts. This is transformed by a secondary winding to a voltage adapted to the capacity of the storage batteries, which they charge. Either of the two large machines charge the ten cells used for talking current at 24 volts and 60 amperes. The third machine used for the 8-volt battery, is capable of delivering 150 amperes at 12 volts. These batteries furnish current for the cord signal lamps. A fourth machine charges at different times, two sets of batteries, a 2-volt and a 4-volt, respectively, the former used for the operators' transmitters, the latter for the line signal lamps. The machine can deliver at its secondary 60 amperes at 6 volts. The ringing and busy back machines, previously mentioned, complete the list of generators. The units are so selected that in case of injury to any one machine resulting from a burnt out armature or otherwise the operation of the exchange is not in the least affected.

It is needless to observe that with metallic service installed, it is possible for a subscriber, without leaving his office, to communicate with a person in any city in the United States where long distance service has been established. Thus it is a common occurrence to send or receive messages to and from Chicago, New York or Boston. In fact the people from the State of Maine may converse with their friends in Nebraska with the same facility and clearness as experienced over a local connection.

A ventilating and heating system of the most modern design is to be shortly installed. The air will be sprayed, dried and heated or cooled before being forced into the operating room, thus offering the most favorable conditions for the operator's prompt and efficient execution of her duties.

The work of removing the ærial wires and cables, poles and cross-arms, so long a menace to public safety, yet a necessary

evil in the business district, is progressing rapidly, and in the near future St. Louis will enjoy the benefits and all that it implies, of a complete, modern conduit system and underground service.

Practical Features of Telephone Work—VI.

BY A. E. DOBBS.

LAYING out routes for pole lines will often require a great deal of diplomacy, as a good amount of purely captious opposition will have to be met and overcome. People living on streets where there are already perhaps one or two pole lines, can hardly be blamed for not wanting to see another one. Some day there may be a law compelling all companies occupying the streets, to agree on the joint use of a single pole line. This scheme is practicable, and would be less troublesome and expensive, than the present cumbersome and unsightly methods. Meanwhile each company has to build its own pole lines, and the fact that the company has a franchise from the town council or street commissioners does not give it the right ot way if property owners object, for city officials often give away what does not belong to them, but the fact that the company holds a franchise for all streets and alleys, can often be used as a successful argument or bluff. It will often be found that the best and cheapest plan is to buy the right of way with the necessary tree trimming privileges. But after all, the point to be gained should be to soothe rather than irritate, for some of these people may be able to throw a great deal of influence for or against the company at some future time, and the new company will need all its friends for they will have fighting enough with the other company.

If possible, the main streets should be avoided; take side streets and alleys. It may take a few more poles, but in nine cases out of ten it will pay. Take for example the map of a town shown in Fig. 16. By following the dots it will be seen

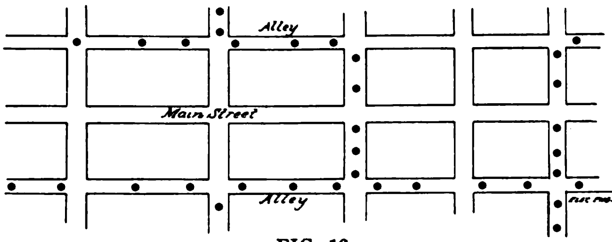


FIG. 16.

that the line almost avoids the main street shown in the centre, and comes into all buildings from the back. It seems to take a few more poles, but in the alleys no obstructions worth mentioning were met, nor paving to be done; no trees in the way worth mentioning, and no objections from property owners; while smaller and cheaper poles were used than would have been possible on the main street.

Again, by going into the alleys the company really covered three streets, so that after all the cost was no greater than to have covered the same territory from the main streets.

Never set a pole in front of a man's house or lot if it can be avoided. Choose the line between two lots, and much objection will be silenced. Poles intended to carry three or four arms should be planted as nearly as possible, 130 feet apart, as they will hold the wires in better shape, and avoid much trouble.

A very good plan used for local distribution at Albany, N. Y., in streets where shade-trees made a pole line an impossibility, was to stretch a No. 6 wire across the street from tree to tree, about 20 feet from the ground to which were tied from 10 to 30 porcelain knobs, at about 12 inches apart, over the centre of the street. The line wires were then drawn through the centre holes of the knobs, and distributed where needed. The span wires were from 100 to 125 feet apart.

POLES.

Cedar or chestnut poles are by all odds better than any others to be found in the Northern States, while in some sections spruce, yellow pine or cypress are the only kind to be had at reasonable cost. In some parts of the country sawed poles are used a great deal, but they do not last as long as the round timber. In some places poles can be procured nearby, in which case it is generally better to cut them in midwinter, for there is a tradition among farmers that they last longer than if cut at any other time, as the sap is then out.

If the plant is being built on a permanent basis, no poles smaller than six inches at the top should ever be used if possible to avoid it, and accept a six inch top only on condition that the pole is stocky and solid otherwise. We have known of contractors using poles as small as four inches at the top, but that does not make it good practice. The part of the pole that goes into the ground, should be treated in some way to prevent decay, either with tar, asphaltum or creosote. Even an oil paint is better than nothing at all. The ends especially should be saturated with it, to prevent the absorption of moisture. In some parts of the West they are put over a fire, or kerosene is poured over them and they are charred at the butts, which is said to double the life of them in the ground. Some companies boil both poles and arms in raw oil or creosote, putting them in a vat for this purpose, which should fill the pores pretty thoroughly, and improve the insulation as well.

Gains for the arms should not be cut more than an inch in depth, and should be soaked with paint before the arms are put on, thus preventing a great deal of dampness and decay at these spots. The top of the pole should also be well saturated with paint, which will prevent warping and splitting. The two top arms on chestnut or spruce poles should be secured by a bolt, for which a hole must be bored clear through both arm and pole, and the pressure relieved by a two inch washer, or better still a plate of 3-12 iron, two inches square. If lag screws are used they are liable to split the pole. Where lags are used on cedar, or green chestnut, they can be driven home, but in seasoned chestnut or other kinds of wood they had best be turned up the last inch with a wrench. Of course all 10-pin arms at least will be braced. The most common brace for this size is 22 × 1 1-4 × 1-8 or 3-16. Standard 10-pin crossarms are of two sizes, known as the short and long arm; one most commonly used in exchange work being 8 feet 6 inches in length. Specifications as follows:

Dimensions	8 feet 6 inches × 3 inches × 4¼ inches.
Distance between two middle pins (centre).........	16 inches.
Distance between all other pins (centre)............	10 inches
Distance of pins from each end (centre)...........	3 inches.
Diameter of pins...........	1¼ inches.
Length of pin to shoulder (lower part).....	3⅞ to 4 inches.
Length of pin from shoulder to top........	4⅛ to 4½ inches.
Total length of pin	8 inches.
Length of thread	2⅛ inches.
Number of threads to the inch....................	5
Depth of threads	⅛ inch.

Specifications for long arm:

Dimensions....... ......10 feet × 4¼ inches × 3¼	inches.
Distance between centre pins	16 inches.
Distance between all other pins....................	12 inches.

Other details the same as for the short arm, except that sometimes the pins are 1½ inches instead of 1¼ inches, but we do not think this is necessary, if the pin is made according to the specification given above. Iron pins are being used a great deal. The best wooden pins are locust, with chestnut second, and oak third; this latter not having the lasting qualities of the first named. The best arms are made of yellow pine, or creosoted white pine. It is also advisable that pins should be well oiled.

INSULATORS.

For wire not heavier than No. 9, what is known as the pony is the cheapest form and as good as any for telephone work. One style of insulator has two grooves and this is often an advantage, for on corners the wire can be dropped down to the second groove, bringing the strain nearer the base of the pin, while on junction poles the tops can be lashed together, while the line pulls off from the lower groove, though a double glass with a skirt between the groove is better for this work.

The double groove glass also makes a very fair transposition glass as it will interpose about 1½ inches between the two wires and while this does not afford the highest insulation between the wires, there is a growing impression among telephone men, that a slight leak at regular intervals is an advantage to the line rather than otherwise. On country lines it is perhaps advisable to use heavier glass—that known as the heavy pony being about the thing—because a country line is never inspected as long as it will work, and the light pony insulators break too easily, and are liable to remain broken for some time, without being observed.

ELECTRIC LIGHTING

Statistics on English Electric Lighting Plants—II.

BY CLAUD P. D'OYLY.

TAKING a cursory glance at Table 1 in the last article, it would seem that direct current plants are more profitable to operate than alternating plants; this is because the business is congested, and the route of the mains is well built up; you do not find as you leave the city the houses getting fewer and fewer per block, until you come to the outskirts, where there is only one house every two or three squares, as we have here in America. Generally, the city is built up thickly, and the houses end abruptly at the edge of some estate, which very likely cannot be sold or built on.

The revenue per eight candle power lamp averages in Great Britain $1.72 for d. c. stations, and $1.56 for alternating current plants. In London the different companies average $2.78 per eight candle power lamp per annum. Some of the engineers of direct current stations took the trouble to make estimates of the amount of money expended on service copper per eight candle power lamp; but this estimate is very hard to make with any degree of accuracy, but was computed on the amount expended for mains and the cost of installing them. But their estimates cannot be considered very accurate, as in some cases it is impossible to separate the cost of the high voltage arc lamp circuits which are put in at the same time in the same conduits; and, moreover, some conduits are laid for eight circuits and only contain one or two circuits; and of course the total expense of this conduit should not be charged to the present installation. On five d. c. plants with 165,000 eight candle power lamps installed, which plants sold 1,800,000 k. w. h., and on which the revenue was $300,000 in 1897, the copper cost per lamp for service wire averaged only $8.52, from which it will be readily seen that direct current would be hard to beat in copper cost. The Board of Trade requires a special analytical report of all electric lighting companies, and this requires constant bookkeeping and analytical work; and as this is in the nature of a public document, all electric light plant managers and engineers were willing to show this report as far as it had been brought up to date, and would take much trouble to make things perfectly clear. This report requires that every detail shall be separately worked out by itself, showing every expenditure and what proportion it is to the gross expenditure, and how much it amounts to per k. w. h.

Table 2 is a partial list of plants owned by municipal authorities, and gives the cost of the plant per kilowatt and per eight candle power lamp.

Table 3 is a partial list of plants owned by private companies, and gives the same figures in a general way, and shows the amount which has been saved by the municipality using ground they already owned and making use of boilers and employés of the gas and water works.

As showing the constant growth of the best installed plants, I have taken two plants in a residence part of London, where the gas competition is the keenest and the price is the lowest.

1897	66,364	1,416	104,000	43,500	60,500

These are both companies furnishing light in residential districts, and it will be noticed that whereas the increase is slow, it is sure, and this accounts for the healthy condition of the manufacturing business, as all these new customers require meters and cut-outs and wiring. In the case of the House to House Company, the average lights per customer has been reduced from 67 to 47, showing that at first the electric light was looked upon as a luxury, and only the very richest people had their houses wired; but later, as the cost was demonstrated, people of smaller means came in and demanded current; in 1890 the average bill was $100 per customer per annum, and in 1897 it was $73 per customer per annum.

In the Notting Hill Company the number of lamps per customer averaged 91 in 1891, and has worked down to 57 at the present time; but the revenue per customer has remained about the same—a trifle over $100; but the price has been reduced from 26 cents per k. w. h. to 16 cents. They seem to have cultivated a taste for electric light and to have done it profitably.

TABLE II.—LOCAL AUTHORITIES.

Towns.	Kilowatt capacity end of year.	Capital outlay per kilowatt.	Capital outlay per lamp.
Aberdeen	430	$350	$9.35
St. Pancras	1,174	480	12.30
Belfast	283	515	13.90
Bradford	1,393	255	9.25
Brighton	1,210	625	10.20
Burnley	330	370	12.20
Dewsbury	250	410	24.10
Dundee	560	315	10.80
Glasgow	1,700	385	8.30
Hull	638	355	9.05
Manchester	3,240	385	12.15
Nottingham	470	570	17.35
Oldham	432	365	13.35
Lancaster	240	450	16.85

Average, $418 per kilowatt and $13.25 per light.

To show the rapid advance of the lighting, it is only necessary to state that some plants have already changed and put on 220-volt lamps on their circuits, and in many more would like to, but are afraid. "It looks too much like going back to the old days of 1883," a prominent engineer remarked to me, "when no one expressed surprise when electrical apparatus smoked or got so hot it could not be touched with the hand; when 220-volt lamps are installed, and trouble comes, the cut-out and socket are blown into unrecognizable pieces." He said that the sudden explosion which blows the covers of cut-outs to pieces is caused by the sudden expansion of the contained air, and must be obviated by using a large cover with perforations. We prefer a cartridge fuse here, with no chance for air to enter or without any chance for the hot air to escape. They approve of the idea of putting a cement plaster around the fuse, as it keeps down the temperature and minimizes the effect of the arc. The increase of business in some cases being 50 per cent. per annum for three years in succession is a very serious matter for the borough engineer who laid out the plans on a basis of the demand for twenty years, especially as the companies have been financed and the sinking fund has been arranged on that basis. A company which sells as Birmingham did, in 1895 496,000 k. w. h., in 1896 756,000 k. w. h. and in 1897 1,133,000 k. w. h., is quite puzzling, as besides having to settle with the stockholders, there is the Board of City Councilmen and the Government Board of Trade Inspector. The corporation is bargaining to gain control of this company, but as this

TABLE III.—INCORPORATED COMPANIES.

Towns.	Kilowatt capacity.	Capital outlay per kilowatt.	Capital outlay per lamp.
Charing Cross	1,050	$1,040	$21.30
Kensington	1,780	575	10.85
Nottingham	330	1,270	20.35

Richmond	290	675	35.70
Southampton	303	315	13.90
Liverpool	2,200	600	19.30

Average, $655 per kilowatt and $17.80 per lamp.

is the first year a 5 per cent. dividend has been declared on the common shares, 1,000,000 dollars, and the stockholders have previously foregone dividends on account of the future prospects, it is a hard matter to arrange equitably.

Sheffield is a plant very well situated and very well managed, which pays this year 12½ per cent. to its stockholders; it has been in operation five full years and the revenue accounts are as follows:

1893	$17,777
1894	24,247
1895	34,675
1896	56,340
1897	71,090

Now the corporation has given notice of its intention to buy the company out and has negotiated for about a year, so as to arrange means of payment and terms. The last offer is to give each holder of stock, $1,100 of corporation, 2½ per cent. debentures for each 500 dollar share, and to pay stockholders such sum as would be equivalent to a dividend of 5 per cent. per annum on all the money invested. The corporation borrows the money at 2½ per cent., and buys the plant on a 5½ per cent. basis, although it is paying 12½ per cent. and is growing. People are conservative and take time to arrive at a decision to make a change in their lighting arrangements, but time is all it requires; there is a great natural growth, and you do not often hear of companies doing free wiring to get customers, although there is a slot meter company which seems to be prospering through a slight discount they get from the customers' bills; but it seems like rather a small economy to admit a middleman into that position, considering the large investment the company has in plant and mains. It seems rather absurd that a company which has invested a sum of $400 per k. w. h. in the stations, or $12 per eight candle power lamp installed, should allow a concern to retail their current.

A bill has been presented to Parliament, giving the electric companies the right to buy property adjoining their plants; it seems to be thought that property which is required for increase of the plant attains immense value in the eyes of the holder. The bill states that as the companies have statutory obligations to fulfil for the convenience of the public, they should have the same rights steam railroads and electric railroads have, to enable them to perform their obligations. There are, of course, two sides to the question, but if the act becomes a law, perhaps if an electric light plant is located next to your house, it will be best to move instanter, and not put up with noise and other inconveniences necessary to a manufacturing establishment, as you may be forced out any time the company chooses, and you are not likely to get such pay for your property as will reimburse you for the inconveniences; you will merely be bought out on a basis of rental for 33 years. The lack of enterprise exhibited in the matter of installing plants is not so surprising, if we look at the matter from the investors' standpoint, and it accounts for the fact that the municipalities have about one-half the plants, and the other half are promoted and owned by the same clique who have close relations with some manufacturers. No water is allowed in the stock, and the chances are that for some years there will be no dividends, and after that, when the dividends are large, the municipality comes in and buys the enterprise up—not on the basis of the present earnings and future prospects, but on the basis of what money has been put into the plant. There is not the same inducement to the promoter as there is when a man can issue unlimited stock, and bonds as long as he can negotiate them. The franchise is looked upon as a valuable asset of the city, lent to the company operating the electric light station, which asset will be called for at some future time; and it makes the matter at any stage rather unsettled, as improvements to take place in a series of years cannot very well be undertaken unless the field of operation is unlimited, and arrangements as to charges for current cannot be made for any length of time ahead. With street railways it is even worse, and the bargains made in some cases by the city are wonderful, and apparently the only way the company leasing from the city can make more than 3½ per cent. per annum is in the amount which can be made in putting in the equipments and trolley lines.

PITTSBURG, PA.—The Allegheny County Light Co. has voted to increase its capital stock from $1,500,000 to $2,500,000, in order to develop its business.

MUNICIPAL AFFAIRS

Municipal Electric Lighting.[1]—IX.

BY PROF. JOHN R. COMMONS.

FOSTER'S ESTIMATES EXAGGERATED.

WHEN, now, we proceed to compare the cost of public with private lighting we see how greatly exaggerated is the estimate of Mr. Foster. He indeed does not make computations for lost taxes, but since this item cannot exceed 1 per cent., and probably should be excluded altogether, and since insurance is included in operating expenses of all the small plants which he examined, his rate of 7½ per cent. for depreciation is fully double a reasonable rate. Mr. Parsons, who makes fixed charges 5 per cent. to cover depreciation, insurance and lost taxes is certainly sufficiently liberal to the opponents of municipal ownership.

The exaggerations of Foster's estimates appear yet more clearly when he compares directly the costs under public ownership with the costs under private ownership. He compares the total cost per lamp hour of the fourteen cities of his investigation which had street lighting plants alone with fourteen other cities having private plants.[2] His averages apparently show that in municipal plants the cost to the city is 1.86 cents higher per hour than in the private plants. But the table is worthless both in method and in fact. 1. Every statistician knows that in getting averages extreme and exceptional cases should be omitted. In these fourteen municipal plants there are three exceptional cases. Alameda, Cal., where he himself says the high cost "throws doubt on the accuracy of the figures;" Fairfield, Ia., a diminutive plant with but fourteen arcs and no commercial lighting; and Anderson, Ind., a plant using natural gas. Two of these cities have exceptionally high costs and one has exceptionally low costs. Excluding them, the average would be 4.13 instead of 4.44 cents per lamp hour. 2. His rate of interest for municipal plants is six per cent. which is fifty per cent. above the correct rate. 3. This rate is computed upon the total cost of plant to date, including new construction paid out of taxes. It should be computed only on the outstanding debt. 4. His rate of depreciation is seven and one-half per cent. which is one hundred per cent. above the true rate. 5. He selects fourteen private plants for comparison which he says are similarly situated (giving no names). But this is impossible, for private plants have always commercial lighting as well as public lighting, and they usually give a lower rate to the city than to private consumers. They can well afford to do so, for thus they keep their hold on the private citizens. The usual method of judging the companies by their rates to the city overlooks the way in which they are depriving the people at large of the advantages of electricity. In Table XI. Mr. Foster selects sixteen private plants the average cost of whose lights to the cities is $.086 per kilowatt hour ($.041 per lamp hour), instead of $.0358 per lamp hour.

Taking the first, second and fourth of these criticisms into account and omitting the others I have drawn up the following table, using the data supplied by Foster himself; and by the side of the estimates which he has made for the fourteen city plants in question I have placed three trial columns showing what would be the cost per lamp hour: first, with interest at four per cent. (the actual rate), and depreciation at seven and one-half per cent. (his rate); secondly, with interest at four per cent. and depreciation at five per cent.; thirdly, with interest at four per cent. and depreciation at three per cent. I have also estimated again for each of the four columns what would be the true averages if the three exceptional cases were omitted. It will be seen that even with depreciation at seven and one-half per cent., as he claims it should be, the average cost to cities is only $.0351 when exceptions are omitted and interest is put at its true rate of four per cent. By the other estimates it is much lower. Thus while Mr. Foster has been candid, a correction of his inexcusable guesses and mistakes of method demon-

[1] Municipal Affairs, Dec., 1897. A Reply to R. R. Bowker. See Elec Engr.

[2] See Table XII., columns 1, 3 and 7, which show according to Foster that the average cost per lamp hour in public plants is $.0444 and in private plants $.0358.

strates with his own data the decided superiority of the municipal plants.

Candle Power per 1 cent.		484	570	613	658	559

(1) These are omitted under "extremes omitted."

Similar corrections also show that in cities with commercial plants the net cost of public lighting, instead of being $.1105 per kilowatt hour ($.0579 per lamp hour), is only $.0668 per kilowatt hour ($.0319 per lamp hour), and is therefore less than when the city has street lamps alone, and is less than when the city private companies, which Foster adduces, by $.0192 per kilowatt hour ($.0091 per lamp hour), a difference of twenty-two per cent. in favor of the municipal plants. The table is reproduced here with these corrections:

DETROIT AND CHICAGO CONTRASTED.

The foregoing analysis of Mr. Foster's statistics is enough to show that the actual results of municipal lighting are superior to those of private operation. The estimates made in the last two columns of Table II. may be considered as marking the extreme cost of municipal lighting, including, as they do, every reasonable charge, and allowing from two to four per cent. more for fixed charges than the facts really demand. In addition to the preceding discussion, I present the following comparisons of interest:

The municipal plant in Detroit for the year ending June 3, 1897, reports the actual cost of 1,564 arc lamps, including interest, depreciation and lost taxes, at $89.42 per year. There were also 3,064 incandescents, making a total of 1,716 full arcs, on the basis of the kilowatt hours of output. The total cost, including interest, four per cent., and other fixed charges, five per cent., was $171,883.56, equal to $100.16 per arc equivalent. I am convinced that this estimate is too high for Detroit, because the underground construction should bring depreciation below three per cent.; also, the cost of the plant, $714,843.76, is $416.57 per arc equivalent, which is $134.07 in excess of the Allegheny plant ($282.50 per arc equivalent), and probably $200 in excess of the cost in private plants which have commercial lighting. The high cost includes underground construction, built in anticipation of future growth of the city. Taking these into account, the estimate of the Commission at $89.42 is more nearly just.

The municipal plant of Chicago was reported by the city electrician in 1896 as furnishing arc lights at a cost of $96.40 for operation. I am informed by the comptroller that the present city electrician thinks this estimate is incorrect "for the reason that not enough is included for the maintenance of the lights and there is no allowance made for the office expenses. He has made a separation of the charges and added in the amounts which have been omitted, and finds that the lights actually cost the city about $117 per light per year," not including fixed charges. Since July 1, 1897, however, the present electrician figures the average cost per light per month at $7.35, including "a fair proportion of office expenses, all repairs and improvements in stations and circuits and all the operating charges. The estimate of the cost per light per year will not exceed eighty dollars, and he has hopes of making it still lower next year. He does not figure any interest on the money invested. A full 2,000 power electric light is furnished, and reports show that the lights are operated a greater number of hours than any other municipal or private plant from which this city has ever received a report. The cost per hour last month was $.0224." As I have no detailed reports from the Chicago plant, I give below the computations above made for Detroit and Allegheny, together with prices charged by private companies in representative citites:

TABLE XIV.

COMPARISON OF COSTS TO THE CITY FOR STREET LIGHTING.

	No. lamps 2,000 c. p.	No. hours per year.	Cost to city.	Cost per lamp hour.	Candle power for one cent.
Municipal plants.					
Allegheny	1,235	4,007	$73.53	$.0183	1,093
Detroit	1,716	3,791	100.16	.0264	757
Detroit, official	1,564	3,791	89.42	.0236	847
Private plants.					
Pittsburg	1,700	3,650	96.00	.0263	760
Buffalo	2,100	3,650	126.00	.0345	580
Columbus, O	990	2,179	74.50	....	585
Indianapolis, Ind.	1,100	2,179	85.00	....	511
Philadelphia	6,500	4,000	$109 to $146	....	498 to 734
New York	...	4,000	146.00	.0365	548

The municipal plant in Allegheny reports that the operating expenses for 1,037 arc lamps in 1896-7 were $53.55 per lamp, having been $61.24 in 1895-6. There were also 3,400 incandescents, and on the basis of the total output in kilowatt hours, these made a total equivalent of 1,235-2,000 candle power arcs. The operating expenses were $73,851.98. There was no debt, and depreciation, lost taxes and insurance on the total value of the plant ($348,921.39) at five per cent. were $17,024.72, making the total cost per full arc equivalent $73.53.

96 Mines for Havana.

A special dispatch from London, of April 13, says: Mr. J. P. Gibbins, who claims to have handled the submarine mines which were intended for use in Havana Harbor, and whose statements have been denied by the Spanish Ambassador here, says that Spain is denying some things that he never said. He reasserts that about ninety-six mines and fourteen tons of guncotton were furnished the Spanish Government for use at Havana by Latimer, Clark & Co., of London.

He, as superintendent of the submarine department of the firm, supervised the shipping of the material. Mr. Gibbins again affirms that he is able to prove absolutely that the Maine was deliberately and wilfully blown up. He says he believes he could fix the act on two men, and even one.

Vol. XXV. NEW YORK, APRIL 21, 1898. No. 520.

Prices for Niagara Power in Buffalo.

THE utilization of electrical current developed at Niagara by industries attracted to the spot has already become an old story. Such utilization is steadily unfolding its successive developments, and the rate of advance will probably accelerate as the uses multiply. The future of Niagara Falls as an industrial centre seems to us assured beyond any peradventure, but that has only been one-half of the problem. The questions that Mr. L. B. Stillwell and his financial and engineering associates have had to determine lately have dealt with the larger problem of the profitable transmission and use of the current generated by Niagara, at points more or less remote, and at Buffalo, for a beginning. We know as a matter of fact, and it will be readily conceded, that the Cataract Power and Conduit Co. has found it a subject of no small difficulty to devise a system of charges applicable to its conditions and fair to all the other parties concerned. It will be remembered that tentatively, the power company began its Buffalo work by delivering current to the street railway system at the rate of $40 per horse power, scaling from that point downward as the quantity increased. But selling current en bloc, on the grand scale, is only one aspect of the Buffalo proposition, for, after all, what has been needed is the satisfaction of the legitimate hopes and claims of all the manufacturing industries that even now are pushing Buffalo to such a high place amongst the great cities of our land. The industries of the city are already varied far beyond any natural supposition, and if we are not mistaken, every Buffalonian worthy the beautiful city he lives in nourishes the desire to use the energy of distant Niagara for all the heating, cooling, lighting and driving, of his home, his factory, his office, or his store.

The executive committee of the Cataract Power and Conduit Co. has just adopted formally its system of rates, which we quote below. Experience alone, and perhaps not that of a mere year or two, can demonstrate whether the figures of the forecast are right, but knowing as we do personally the officials and experts who have been working on the many problems involved, we venture to express our belief that time will pretty exactly justify them. Not only have local conditions been considered, but those of other communities; and the rights of both the large and the small consumer of current have been weighed and adjusted. The rates are for three-phase alternating current delivered on the premises of the user at a potential of 2,200 volts. Under the contract existing between the Cataract Power and Conduit Co. and the Buffalo General Electric Co., users of power requiring not more than 75 e. h. p. shall be kept at their disposal, will be supplied by the latter concern, except in cases where it may be more feasible to reach them by the circuits of the Conduit Co. It may be inferred, as natural, in such a development, that for the present the practical application of the rates will be limited to the larger users of power; but it is understood that the Buffalo General Electric Co. contemplates an early revision of its schedule of charges, which will, in turn, secure to the users of smaller quantities of current, a fair share in the undeniable advantages of Niagara power.

Coming now to the rates themselves, we quote them below. The monthly charge for power will depend upon the actual amount used, as determined by standard meters installed by the Conduit Co. upon the premises of the consumer. These meters record the number of electrical units which are actually taken by the consumer. The standard electrical unit of power is the kilowatt hour, equivalent to about 1⅓ h. p. hours. The charge for power will be determined by the record of the meter and by calculation from the following schedule:

For use not exceeding 1,000 units, the rate shall be two cents per unit.

For use exceeding 1,000 units, but not exceeding 2,000 units, the rate shall be: For 1,000 units two cents per unit, and for the excess one and five-tenths cents per unit.

For use exceeding 2,000 units, but not exceeding 3,000 units, the rate shall be: For 2,000 units one and five-tenths cents per unit, and for the excess one and two-tenths cents per unit.

For use exceeding 3,000 units, but not exceeding 5,000 units, the rate shall be: For 3,000 units one and two-tenths per unit, and for the excess one cent per unit.

For use exceeding 5,000 units, but not exceeding 10,000 units, the rate shall be: For 5,000 units one cent per unit, and for the excess eight-tenths of a cent per unit.

For use exceeding 10,000 units, but not exceeding 20,000 units, the rate shall be: For 10,000 units eight-tenths of a cent per unit, and for the excess seventy-five hundredths of a cent per unit.

For use exceeding 20,000 units, but not exceeding 40,000 units, the rate shall be: For 20,000 units seventy-five hundredths of a cent per unit, and for the excess seven-tenths of a cent per unit.

For use exceeding 40,000 units, but not exceeding 80,000 units, the rate shall be: For 40,000 units seven-tenths of a cent per unit, and for the excess sixty-six hundredths of a cent per unit.

For use exceeding 80,000 units, the rate shall be: For 80,000 units, sixty-six hundredths of a cent per unit, and for the excess sixty-four hundredths of a cent per unit.

In addition to these charges for power, there will be a charge for "service" of about 75 cents per horse power per month. The current will be delivered at the start from three sub-stations, others following as the business grows. The company points out that a charge of $40 per horse power per annum may be a fair charge in the case of a user who requires a block of 300 horse power, and uses it twenty-four hours per day, but it is obvious that such a charge would be excessive if applied to the case of a grain elevator requiring that 300 horse power be kept continually at its disposal, but using that amount of power intermittently. It is evident, also, that the Cataract Power and Conduit Co. can afford to keep 300 horse power at the disposal of the elevator for a less sum than it is compelled to charge the customer who uses this full amount continuously during each twenty-four hours. The next step will be, of course, the installation of plants taking this power, and then we shall all be deeply interested in seeing how the results compare with those obtaining under the old regime of current generated on the spot, from coal and natural gas.

Clarke's Lecture on Wireless Telegraphy.

SINCE the epoch-making discovery of Prof. Röntgen a little over two years ago, which created such a stir in the scientific world and has conferred such incalculable benefits on mankind, no subject has engrossed the attention of the public to such a degree as the invention of wireless telegraphy and the manufacture of liquid air. These subjects have fairly monopolized the scientific press and have found large and interested audiences to witness the novel experiments, which naturally awakened in the inquiring mind an interest in the principles underlying their operation and in the final, practical applications to which they may lead. And, while there may be many silent workers on both problems, it is a curious fact, that in this country but two men have given out freely the results of their labors in these directions to the public, namely Messrs. Tripler and Clarke. A lecture was delivered by Mr. Clarke before the New York Electrical Society, and some of his results were published in our columns last week; and the very an-

imated discussion which it elicited cannot help but lead to very beneficial results. The discussion which was participated in by Dr. Pupin and Messrs. Mailloux, Dunn and Clarke dealt principally with the following points, which appeared from the discussion to be far from being settled or agreed upon: (1) The use of plates instead of wings, the essential feature being the length of the plates, and not their cross section, and the necessity of having them placed parallel to each other. (2) What takes place inside of the tube of the coherer, whether there is actual motion of the particles or a fusing action due to small sparks, or the elimination and re-establishment of a film of air between the particles. (3) The method of winding the high resistance relay coils without inducing self-induction in them. This is done by winding them in several coils and connecting in multiple. (4) The working of the transmitting device when the entire set of apparatus is enclosed in an iron box. (5) The practical application of the invention. Such uses as communication between ships and the shore, and telephoning without wires were discussed. The accurate tuning of the apparatus to prevent interference of signals was suggested, but no practical method for doing this has as yet been proposed. (6) The number and size of the balls on the transmitter and the distance between them was then taken up, and experiments seemed to show that the size of the balls has to be increased the greater the distance between the receiver and transmitter. Dr. Pupin expressed the belief that in the case of grounded circuits, it is not so much the action of the waves transmitted through the air that affects the coherer as it is the ground current running between the two plates. These plates are actually the two plates of a condenser which is being charged by the induction coil and the charging current causes the resistance of the coherer to diminish. Finally, Dr. Pupin believed that Mr. Marconi's apparatus does not represent the solution of the most important problem in connection with long distance signalling by means of electrical waves. He pointed out the necessity of using waves having very short periods and a small decrement. They should have very short wave lengths, so as to enable us to construct reflectors of reasonable size which could focus them, and they should have a small decrement, so as to be capable of producing powerful resonating effects, for without that selective signalling becomes impossible. So far as he knew, nobody has been able yet to produce electrical waves of excessively short period, and at the same time possessing small decrement, because to produce these rapid oscillations it is necessary to connect small conductors to the terminals of the induction coil, and in such cases the radiation of the electric waves is so enormous that the waves die out very rapidly, so that after the first half wave there is hardly anything left. This was the trouble for instance with the waves produced by Prof. Lodge and others. It was on that account that successful experiments on the reflection, and the interference of electrical waves became almost an impossibility. In a recent discussion given by Prof. Lodge and published in the "London Electrician" this difficulty, said Dr. Pupin, has been emphasized more or less forcibly. Now, as Mr. Marconi offers no suggestion in the line of solving this problem, and without the solution of this problem, selective signalling by means of electrical waves will be made an impossibility, Dr. Pupin thought that the commercial utility of the system will remain more or less small.

The Dangers of Excessive Conservatism.

IN a recent issue of an English contemporary we note in an editorial comment on the subject of American competition in Europe the remark that "Our (English) great fault, as a nation, is excess of conservatism." Seldom have truer words been spoken, but they are not true of England alone nor are they limited in their meaning and pertinent application. We find, for example, this same conservatism among mechanics in the shops who either oppose new methods or try to keep to themselves some antiquated trade secret that might benefit others. There are also individual companies whose excessive conservatism too often means the creation of suspicion on the part of the public on whose patronage they are dependent. This lack of faith is frequently unfounded and can only be eliminated by the adoption of a more liberal policy on the part of the management. It certainly cannot be their desire to hide from the purchaser the good features of their apparatus. The patent office grants them due protection on any new device or process, and only by an interchange of ideas or their publication can progress be made. Fortunately, America, one of whose proud possessions has always been its conservatism, has never carried this trade reserve to excess. The literature issued by American electrical manufacturers is becoming an important educational factor, besides having its purpose of advertising their goods. But our companies have long gone beyond this stage of imparting by catalogues a knowledge of their machines and methods. Instances of even more laudable methods are the very able and comprehensive series of articles in our late issues by Mr. Gano S. Dunn, who describes the design and important details and applications of the apparatus manufactured by the company of which he is chief engineer; and the article by Mr. Harry H. Cutler on "Motor Regulation and Control" concluded in this number. Articles such as these, written by men who have themselves designed and superintended the construction of standard apparatus are of the greatest value to the engineer and student.

Inventors, we might add, are a last class whose conservatism or secretiveness hinders them from realizing their ideals or reaching the goal. The art makes the quickest advance that has not one inventor working at it but fifty. In fact, it might almost be said that no new art is possible until its underlying ideas have become the common property of several fertile minds. These inventors toiling in a common field, deriving their common inspiration from one source, may regard each other askance and even speak of each other harshly, but in reality they are stimulating each other, helping each other along and perpetuating their art on solid bases. Conservatism is isolation. No art dies that has more than one practitioner. No invention succeeds until it has ceased to be the private ownership of one man.

EDUCATIONAL

Lectures at Purdue University.

The students of the Electrical Engineering Department of Purdue University, Lafayette, Ind., are to be especially favored this spring in the matter of visiting electricians who will address them along professional lines. Prominent among the list of the non-resident lecturers at the university are the names of Mr. Samuel Insull and Mr. Albion E. Lang, distinguished gentlemen who have already done much to advance the electrical interests of the country, and who stand at present among the most advanced thinkers and workers of America.

Mr. Lang, who is president of the Toledo Traction Co., and of the American Street Railway Association, will deliver an address at the university on the subject of "Electric Power Companies and Their Relation to Municipalities," on the 26th of this month.

Mr. Insull is at the head of the Chicago Edison Company, and is president of the National Electric Light Association. He will visit the university on May 17 and will lecture on the subject of "The Development of the Central Station."

Columbia University, N. Y.

The Electricity, Physics and Engineering Departments had their turn on Saturday last at the series of "University Teas," and it is said to have been the best of the lot, every condition favoring, the sunny spring weather bringing out crowds of society folk and showing off the new buildings and grounds to the utmost advantage. In the Physics Building, Prof. Hallock was to the front with a corps of ladies, and in the Engineering Building, Prof. Hutton was the most cordial of hosts. As for Electricity, it suffices to say that the hospitalities were extended by Dr. Pupin, Prof. Crocker, and Assistant Prof. Sever, who spared no pains to show things, especially to the ladies, who hung spellbound on their esoteric utterances. The gathering of well-known physicists, mechanical engineers and electrical engineers was wonderfully large and representative.

MR. HERBERT S. WYNKOOP has been appointed by Commissioner Kearny an inspector of gas and electricity at a salary of $2,000 per year.

Considerations Governing the Design of the Crocker-Wheeler Slow Speed Motors.—IV.

(Concluded.)

BY GANO S. DUNN, CHIEF ENGINEER.

It was a mooted question when motors of this type were first employed, whether they had any advantages other than compactness and convenience to set off against their greater cost and lower efficiency. Experience has shown that, for the equipment of new machinery where the attaching lugs, frames, etc., can be made at the place of manufacture, the first cost of

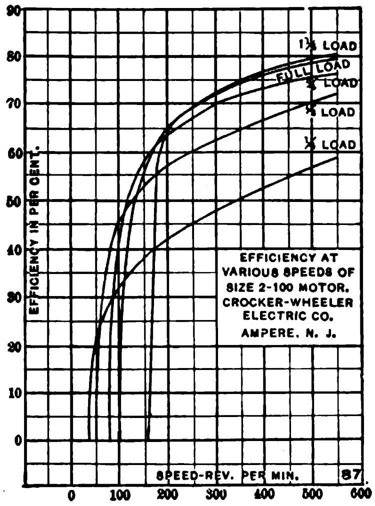

FIG. 6.—EFFICIENCY AT VARIOUS SPEEDS OF SIZE 2-100 C. W. MOTOR.

a direct motor in view of the omission of tight and loose pulleys and belt shifting devices, is not much different from that of a high-speed combination, erected in place, involving the cost of its gears and pinions to reduce the speed; but in the case of attachment to presses already built the advantage in cost,

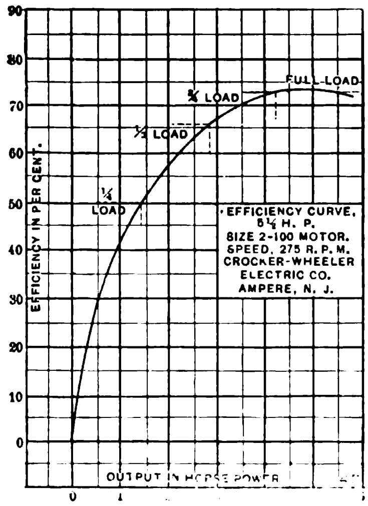

FIG. 14.—EFFICIENCY SIZE 2-100.

although not great, is with the latter. Similarly, as regards efficiency, a rule cannot be laid down, since the efficiency of the direct motors depends considerably on their speed. At the speeds at which printing presses usually run, from 100 to 250 per minute, the efficiency is about equal; below these speeds it favors the high-speed geared-down motor; above them, the direct motor.

To show how the efficiency of direct motors is affected by speed, we repeat Fig. 6, where, with efficiencies as ordinates and speeds as abscissæ, are plotted five curves giving the efficiency of a size 2-100 motor for normal speeds from 0 to 500 r. p. m. at the five points of ¼, ½, ¾, full, and 1¼ load respectively. It will be observed that the values drop very rapidly as the lower speeds are reached.

While the efficiencies are much lower than those of standard

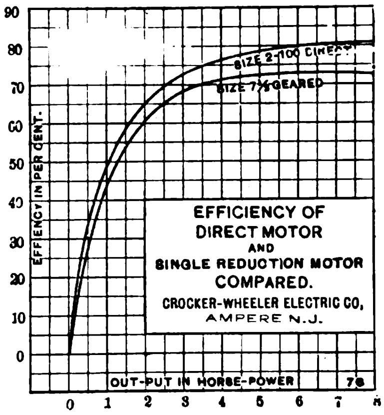

FIG. 15.—COMPARISON OF EFFICIENCIES OF DIRECT MOTOR AND SINGLE REDUCTION MOTOR.

motors, it is not because the machines are less carefully or liberally built, but because in proportion to their outputs, which are small in consequence of their low speeds, their losses form a large percentage. The efficiency of the 5½ h. p. motor is shown in the accompanying diagram, Fig. 14.

Fig. 15 shows the efficiency, after the speed-reducing mechanism has been included, of a high-speed motor geared down, and compares it with that of a size 2-100 running at the speed of the countershaft.

The various tools and machines to the driving of which these slow speed motors are applicable, are evidently very large. We can illustrate only a single example, namely, the printing press. An installation of this kind is shown in Fig. 16, which shows a ½-100 motor driving a quarto-Thomson press, and a 2-100 driving a No. 0 Whitlock press.

While designed principally for use as motors, these slow machines make excellent dynamos for direct connection to small gas and steam engines. These usually run at speeds varying

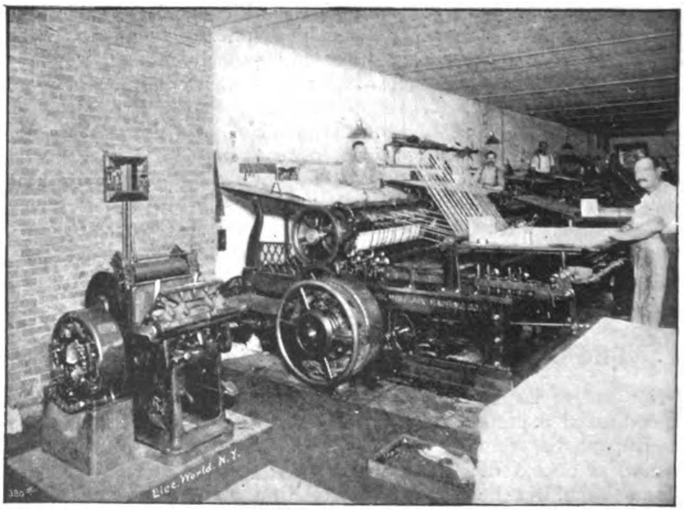

FIG. 16.—SIZE ½-100 on QUARTO-THOMSON OR UNIVERSAL PRESS, AND SIZE 2-100 ON No. 0 WHITLOCK PRESS.

from 300 r. p. m. to 500 r. p. m., sufficiently high to make possible an armature winding, whose resistance will come within the limits prescribed by good regulation for dynamos. For their size these dynamos are very efficient, their efficiency being practically the same as for motors of the same speed.

On account of the very large diameter and short length of armature which results from having more poles than dynamos of such small capacity usually have, they may frequently be con-

nected to engines without the use of a third or outboard bearing, which adds to the fine appearance of a combination and makes an important saving in floor space occupied, a valuable consideration in many cases—marine service, for example.

Fig. 17 shows a size 1-100 directly connected to a Sturtevant

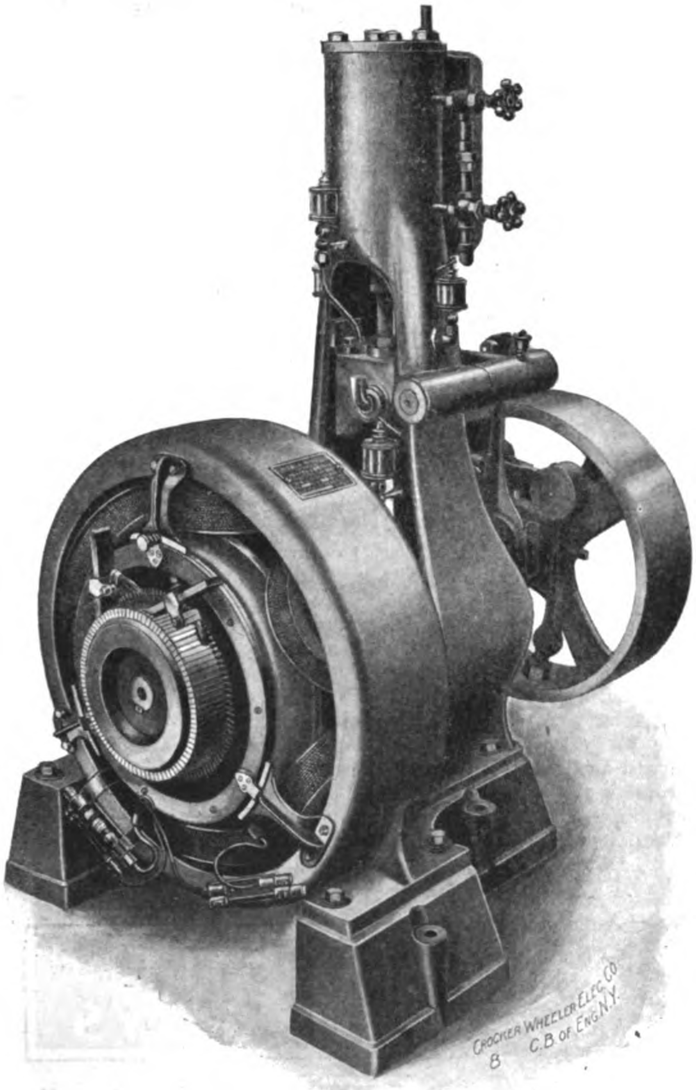

FIG. 17.—SIZE 1-100 DYNAMO DIRECT CONNECTED TO 4 x 4 STURTEVANT ENGINE.

4 x 4 engine at 500 r. p. m., giving an output of 3 kilowatts at 80 volts, for U. S. Torpedo Boat No. 8. The efficiency of this dynamo is extremely high for a small machine, being 80 per cent.

The Regulation and Protection of the Electric Motor.[1]—II.

(Concluded.)

BY HARRY H. CUTLER.

WHEN an elevator is coming down with a heavy load the motor has no work to do and consequently has a tendency to run away, being driven by the weight of the elevator. If the motor is plain shunt wound and its field kept at constant strength, the load on the elevator will tend to drive the motor so much above its normal speed that it becomes a generator, and returns current to the line. The speed of the motor will then increase until a potential is reached sufficiently above that of the lines to consume the power derived from the effective weight of the elevator. The motor will continue to revolve at this speed, which in case of the plain shunt wound motor would not be a dangerous speed. But plain shunt wound motors are now seldom used for elevators; almost all builders of elevators use compound wound motors, or at least shunt motors whose field is weakened after starting.

[1]Read before the Chicago Electrical Association, April 1, 1898.

Motors which bring an elevator to full speed by weakening the field would run much faster when driven by a heavy load on the elevator, and it becomes necessary for the attendant to check the speed by moving the lever back and thus strengthening the field. Should the attendant move the lever so far back that external resistance is inserted into the armature circuit, the speed of the elevator would be increased instead of decreased, as at first might be supposed, and a dangerous speed would result. This curious condition of affairs is due to the fact that with external resistance in the circuit with the armature when the motor is running as a generator, it will have to run enough faster to produce sufficient potential at the brushes to overcome the external resistance and deliver to the line the increased potential necessary to check the speed of the motor.

The application of the electric motor to the printing press is another problem full of interesting points, which time will not permit of taking up, and we will pass on to the second part of the subject.

THE PROTECTION OF A MOTOR.

Motors burn out when overloaded, because they get hot. They frequently burn out also because currents of high potential are allowed to occur which puncture their insulation. Excessive currents scar the commutators and foreign materials produce circuits which lead to damage.

To properly protect a motor from damage by the electric current, these four effects must certainly be guarded against.

Motors can only become dangerously hot by abnormal currents being allowed to flow for an appreciable length of time. A current of double or treble that of the continuous safe carrying capacity of the motor will not do the slightest harm, unless allowed to flow long enough to overheat the motor. When such abnormal currents last only a few seconds it is neither necessary nor desirable for the protecting device to operate, and a properly designed protector should not operate unless the temporary abnormal currents exceed this amount, or last long enough to overheat the motor. Since it is the heating effect of the current which causes an overloaded motor to burn out, the most natural protection would be a device that operates through the influence of this same heating effect of the current. The well known fuse was therefore recommended for this work and the electrical trade accepted it without question. As motors came into more general use it began slowly to dawn upon the electrical profession that they were being misled in their implicit faith in the fusible cut-outs offered by the trade. Too many motors supposed to be protected by fuses burn out, and experiments show that the ordinary commercial fuse will blow at almost any amount of current or not at all, just as it happens to feel at the time.

The manufacturers then attempted to more thoroughly standardize their fuses, and even made a faint attempt to standardize the cut-outs for holding them.

College professors took up the subject and made careful tests and wrote able articles about standardizing fuses. The conclusion which came was that the chief trouble lay in the fact that the fuses in common were so short that the terminals and blocks to which they were fastened caused their blowing point to vary, by conducting off heat which would otherwise have caused the fuse to blow. This they said could be entirely overcome by using fuses 6 or 8 inches long, and then we would have reliable fuses. Not enough significance appears to have been given to the cooling effect of the ever varying drafts of air to which the ordinary commercial fuse is exposed, and therefore to expect any exposed fuse, no matter how long, to blow at a certain predetermined amount of current, appears to the writer to be little short of an absurdity. People naturally become disgusted and look around for something better with which to protect their motors. Into this breach the magnetic circuit breaker bobbed up serenely with its claim for perfection.

The magnetic circuit breaker recognizes nothing but amperes, and takes no account of whether the motor is hot or cold. Now, amperes do not of themselves burn out our motors, it is the heating effect of these amperes, caused entirely by the length of time which they are allowed to flow. Volts on the contrary care nothing about time, so to speak; when the voltage gets high enough the current jumps, and the damage is done instantly, not through ordinary heat, but by the irresistible heat of the electric arc, which volatilizes the wires themselves. It should be noticed, however, that the excessive abnormal currents cause instant damage to the commutator of a motor, if not

to the armature itself, and should be cut down as quickly as possible. This latter office, the ordinary commercial circuit breaker will generally perform satisfactorily. It becomes a nuisance, however, by opening the circuit and interrupting the service at every little temporary abnormal fluctuation of current, which current would not do the slightest harm and calls for no protection. What is needed then for properly protecting the motor is, first, a device that will not allow extremely abnormal currents to flow into the motor at all; second, one that will allow slightly abnormal currents to flow through the motor, until the motor begins to approach a dangerous temperature; and third, the device should check an excessive flow of current so that no undue strain will be put upon the insulation of the motor. No such ideal protection exists to-day, to my knowledge.

The first requirement would be very difficult to meet, and the best that has been done so far is to stop the flow of an excessive current through the motor as quickly as possible. The other two requirements are more easily complied with. To protect a motor from heat it is evident that the heating effect of the current should be utilized in the protcetive device. This is accomplished in at least two devices now on the market, namely, the enclosed fuse and a peculiar make of circuit breaker, designed by the writer. Both of these devices are shown by samples on the table. The enclosed fuse shown is of the D. & W. make, and the fibre case has been removed in order to show its construction more clearly. The distinguishing feature of this fuse is the enclosed air chamber, around the fuse proper, consisting of a gelatine capsule, similar to those used by apothecaries for filling with quinine and other medicines.

The fuse proper is very short and is contained entirely within the capsule. Copper wire leads are connected to the fuse and lead out to the terminal caps, through closely packed sand or plaster of paris. The capsule provides a definite amount of air within which the explosion takes place, thus greatly increasing the accuracy of blowing at predetermined currents. The force of the explosion is taken up by the layers of sand on each end and as there is no air and but little metal to feed the arc, it immediately goes out. These fuses are surprisingly accurate, and being absolutely sparkless, would certainly appear to be an ideal protection both for the motor and as against fire. They are ahead of the times, however, and the vast majority of those who operate motors still cling to the old bare fuse, working in the open air, for the protection of their motors.

Circuit breakers are being introduced very rapidly, however, as a protection for motors, and I have one here which is constructed on a somewhat different principle from anything on the market.

The action of this circuit breaker depends upon the combined magnetic and heating effect of the current. Its mechanical construction is very similar to the usual type, the chief difference being that the magnet or solenoid used to release the trip or catch, carries only a portion of the current passing through the breaker. The rest of the current is shunted around the active coil of the circuit breaker, just as Edward Weston does in his well-known station ammeters. The shunt used in this circuit breaker, however, is composed of material whose resistance increases very rapidly as it becomes heated. The action of this circuit breaker is very simple. On starting up a motor under load, both motor and circuit breaker are cold, the resistance therefore of the shunt on the circuit breaker is at its lowest point and it carries then the largest part of the current flowing through the breaker. As this current continues to flow the shunt heats up, its resistance increases, and more current passes through the magnet or active coil, which will finally act, should the abnormal current last long enough to become dangerous. It is also evident that an extremely abnormal current or a short circuit would not wait for the heating effect of the current, but would cause the breaker to open instantly.

In practice these breakers are generally so proportioned as to allow a current of 50 per cent. greater to flow for a second, than would finally open the circuit if allowed to flow for a minute or two. Any current over 60 per cent. greater than the continuous current which would finally open the circuit breaker, will do so instantly.

A modification of the circuit breaker is the so-called overload attachment to motor starting boxes provided with the magnetic release. One of these boxes can be seen on the table. They are frequently spoken of as an under and over load motor starter. All the various makes of this type of motor starter use an electro-magnet for retaining a switch or rheostat lever in closed circuit position. This retaining magnet is wound so as to connect in series with the shunt field, in series with the armature, across the lines or in series with external resistance across the lines. The overload magnet is invariably connected in series with the armature and carries usually the entire current supplied by the motor. When the current becomes excessive it attracts its armature and demagnetizes the retaining magnet by short circuiting or opening the circuit of the windings of the retaining magnet. There are also several other ways of demagnetizing the retaining magnet.

A surprising degree of accuracy and reliability can be obtained in this way of protecting a motor from overloads. The system has, however, one chronic fault, which appears to have been entirely overlooked, and that is, that no device constructed on the above principle can possibly act quickly enough to protect a motor against extremely abnormal currents, short circuits or lightning, notwithstanding all circulars and advertisements to the contrary. It takes time to demagnetize a magnet, no matter whether it is short circuited or open circuited, and this time is fatal on short circuits, and the motor will not be protected. We must then choose some combination of the various methods just described of protecting a motor. We have here on the table such a combination, which would appear to afford adequate protection for the least money. This device utilizes enclosed non-arcing fuses, the magnetic release, overload magnet, and double pole knife switch. The magnetic release affords ample protection from liability to damage from interrupted current. The overload magnet takes care of all ordinary overloads, and also performs the office of an ammeter which will indicate the approximate load on the motor at any time. The fuses are selected so as to blow on 100 per cent. overloads up to short circuits. The overload magnet can also be provided with the time limit device, described above in connection with circuit breakers. This method of protecting a motor is laid before you for your consideration, and I desire to place myself on record as believing that with such a device on the market for protecting a stationary motor, there are very few places or conditions where the ordinary magnetic circuit breaker will afford equal protection and satisfaction, or be provided at as small a first cost.

New Designs in Static Machines—The Jewell.

THE use of static machines for X-ray work has given a decided impetus to the improvement in design and manufacture of this hitherto rather neglected type of instrument. Various concerns are putting out static machines regularly of a size and perfection that could heretofore be found only in private laboratories for which they had been made specially to order. A representative of The Electrical Engineer was recently much interested upon being shown a new static machine designed by W. S. Jewell, electrician of the McIntosh Battery and Optical Company at Chicago. The results from this machine are quite remarkable considering its small size. It is a modification of the Toepler-Holtz machine in principle, has four 25-inch plates and is self exciting, and a nine-inch spark has been obtained from it. The most striking thing about the machine, however, is the ease with which it runs, due to the fact that ball bearings are used. A 12-inch fan motor of Western Electric make is sufficient to drive it, and in fact after the machine is up to speed it will continue to run for a long time by momentum, quite contrary to the habits of machines with plain bearings. Another point demonstrating the efficiency of the ball bearing was noted by the writer, viz., that when the machine was allowed to slow down and stop of its own accord with a charge on, the attraction of a charge on the plates would make the plates revolve backwards a part of a revolution after the first stop, the action being of course the same as a static voltmeter. In size this little machine was only about half that of one of corresponding generating capacity standing near it, of the old design.

MECHANICAL

Instrument for Delineating Topographical Peculiarities and Measuring and Recording Distances.

THE demand for a speedy method of making preliminary surveys without the usual array of engineers and instruments, seems to have been met by a device, recently invented by John Riddell, of the General Electric Company, Schenectady, N. Y., and entitled "An Instrument for Delineating Topographical Peculiarities and Measuring and Recording Distances."

It is small and compact and may be mounted on a bicycle or upon any wheeled vehicle drawn by horses or pushed by hand or foot. It is shown in Fig. 1 mounted on the horizontal upper bar of a bicycle and consists, briefly, of a vertical revolving cylinder carrying the record, and a marker moved upwards and downwards by the inclination upwards or downwards of the upper bicycle bar.

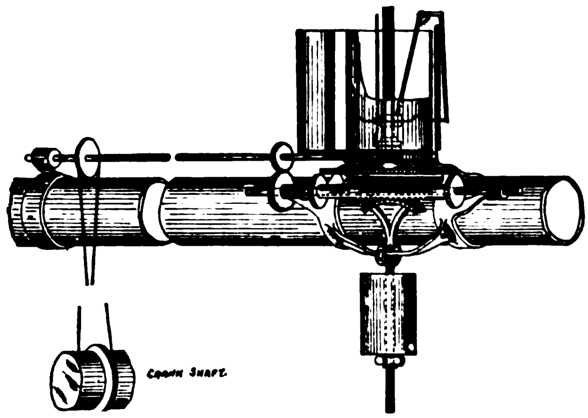

FIG. 1.—RIDDELL RECORDING INSTRUMENT MOUNTED ON A BICYCLE.

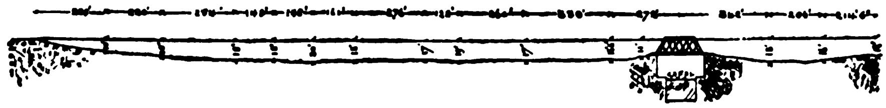
The metal cylinder carrying the paper for the record is provided at the lower end with a worm wheel engaging with a worm on a shaft running toward the rear of the bicycle and driven by a lace belt from a pulley on the crank shaft. Movement of the bicycle produces, therefore, revolution of the record cylinder, which, as it revolves, unwinds the paper for the record from a small drum.

The marker is mounted on a nut on a threaded vertical rod, movement of which raises or depresses the nut and the marking point. The lower end of the rod is fastened to a horizontal disc free to move clockwise or the reverse. Beneath the disc, and just clearing it on each side, are two smaller discs, at each end of a toothed sleeve, and revolving vertically. Through the sleeve passes the disc shaft provided with a gear wheel meshing into a small gear on the main shaft driven from the crank axle.

Suspended beneath the bar of the bicycle, and, consequently, beneath the entire machine, is a pendulum having at its upper end a toothed quadrant, meshing into the teeth of the sleeve on the shaft carrying the vertical discs. As the small discs revolve in the same direction, one in contact with the large horizontal disc revolves it clockwise and causes the marker to ascend, the other counterclockwise depressing the marker. The nearer the centre of the large disc the small disc comes, the faster the former moves and the sharper the angle described by the marker.

It will be seen that the pendulum hangs vertically whatever be the angle of inclination of the bicycle. If the machine is ascending the horizontal bar assumes an obtuse angular position to the pendulum, the rear vertical disc is brought beneath the horizontal disc and the marker moves upward; if a declivity is descended, the angle of the bar and the pendulum becomes acute, the forward disc comes into play and the marker moves downward. On the level both vertical discs are out of contact with the horizontal disc and the marker records a plain horizontal straight line.

A part of a record is shown in Fig. 2. The number of feet above the level are shown by the horizontal line, the distance traveled by the length of the record. It is part of a record made on a wheel ridden from the gates of the General Electric Company's factory to the main street of Schenectady.



PORTION OF RECORD MADE BY RIDDELL RECORDING INSTRUMENT.

The value of a device of this character will readily be appreciated by military, civil and railroad engineers. At present if a piece of road requires survey, or the lay of the land in a certain direction is to be ascertained, a system of survey is necessary involving considerable time and labor. Recent mention was made of the rapidly accomplished survey of 49.22 miles in 19 hours by means of a bicycle and compass. The mapping of the line surveyed occupied several hours additional labor. With a device of the character of that mentioned the completed topographical profile could have been ascertained in the time taken to propel the wheel over the length of the road surveyed.

It could also be widely used by bicyclists and drivers of horses or livery stable keepers and in the development of road maps, which, at present, give distances and rarely gradients.

MISCELLANEOUS

The High Tension Electric Storage Battery.

STORAGE batteries have in the past been constructed in a great variety of shapes embodying numerous ideas intending to increase their efficiency or their life. But what may fairly be claimed to be the most remarkable storage battery, which has yet come under our notice, is that now employed in furnishing current for lighting the town of Souderton, Pa., a place of some 3,000 inhabitants situated about 30 miles from Philadelphia.

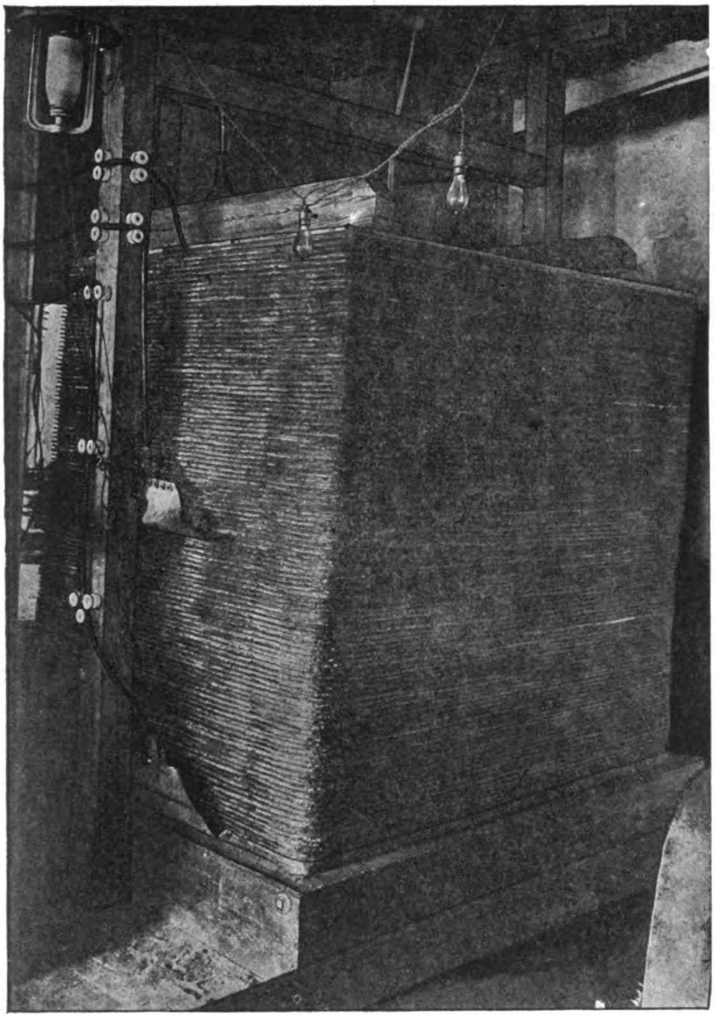
Imagine a structure, as illustrated in the accompanying engraving, Fig. 1, consisting of 110 lead plates piled one above the other, each plate 6 feet wide by 7 feet long, the total height of the battery being 7 feet, and weighing no less than 16 tons; and what is particularly striking, the whole being exposed without any enclosing tank whatever. Such is the structure which meets the gaze of the observer.

Before going into the details of the construction of the cell it may be well to recall that it is now several years ago that Prof. N. H. Edgerton, whose electric motor will be recalled by many electrical engineers, whose memories go back to the beginning of electric motor work, conceived the idea that a battery could be made which would furnish any desired potential and in a form practical for every class of work. Striving along this line, Prof. Edgerton's work finally crystallized into a type of battery, in which each plate formed as it were a couple by itself, one side acting as the positive and the other as the negative in a battery, and thus, at the very outset reducing the number of plates required one-half.

The next problem was to so group these plates that they could be maintained in position so as to permit of the introduction of the necessary electrolyte, and to keep it in place.

With this explanation of the principle involved, we may return to the large battery already referred to. Each plate of this cell, excepting the one at the bottom, is coated on its under side to the depth of one-eighth of an inch with litharge. This

forms the negative side of the plate. In the hollow on top of the plate is a layer of red lead also one-eighth of an inch in



• FIG. 1.—SINGLE CELL 220 VOLT HIGH TENSION STORAGE BATTERY, SOUDERTON, PA.

thickness, which is covered with a thin sheet of asbestos, and on this again is spread a layer of granulated oak charcoal, covered with a sheet of muslin. The plates thus prepared are piled one on top of the other, the result being that, as above stated, each plate constitutes in itself a positive and a negative, with a result that there is an e. m. f. of 2.2 volts between each two contiguous plates. The electrolyte, of sulphuric acid, is syphoned in between the plates and is absorbed and held in place by the granulated charcoal.

In the large battery illustrated, 110 plates of this kind are piled one on top of the other so that at the terminals there is a pressure of 220 volts. Actual measurements with a Weston voltmeter showed a difference of potential of 225 volts on open circuit, and its normal capacity is 3,000 ampere hours.

This large cell is located in the works of the High Tension Electric Storage Company at Souderton, Pa., and, as stated above, furnishes current for all the public and private lighting in that town, consisting of 24 arcs and 600 incandescents, the latter connected to three-wire circuits.

For the charging there are employed three dynamos, two of forty kilowatt capacity, respectively of the Eddy and C & C type. One of these machines is of 250 volts and the other 500. A third machine built by the Electro Dynamic Company is of 110 volts and is employed as an equalizer to feed such size of the 220 volt battery, which may require to be brought up in charge equal to the other side when the two sides are unequally drawn upon. This great cell is charged at a density of 250 amperes, but this can be raised to 2,000 for a short time without injury.

The advantages claimed for this type of a cell are that in the first place it is impossible for any of the active material to fall away from the plate, so that it constantly maintains its original capacity; while at the same time preventing short circuiting between the plates. It is also pointed out that the current passes through from one plate of the cell to the other with absolute uniformity of density, each square inch giving out and receiving an equal current at every point on the plate so that the action on the active material is absolutely uniform throughout. Then again the question of terminals is practically done away with as there are only three terminals in the whole battery of 220 volts, one at each end plate, and one in the middle.

While the battery just described represents the largest work of the company thus far undertaken, it is evident that there is practically no limit to the potential which can be obtained by cells constructed in this manner. As a matter of fact, we are informed that the company is now about to undertake, on an order, the construction of a battery to deliver 1,000 volts.

It will be evident, however, that besides central station work the battery is particularly adapted for private plants and for portable work. Thus, among the electric lighting plants equipped with the High Tension storage battery, is that in the Independent Building at Souderton, Pa., where twenty 16 candle power lamps are installed, operated from the storage battery. This battery is charged with a dynamo run by a 2 horse power Witte gasoline engine, which also furnishes power to run a large cylinder press and paper folder at the same time.

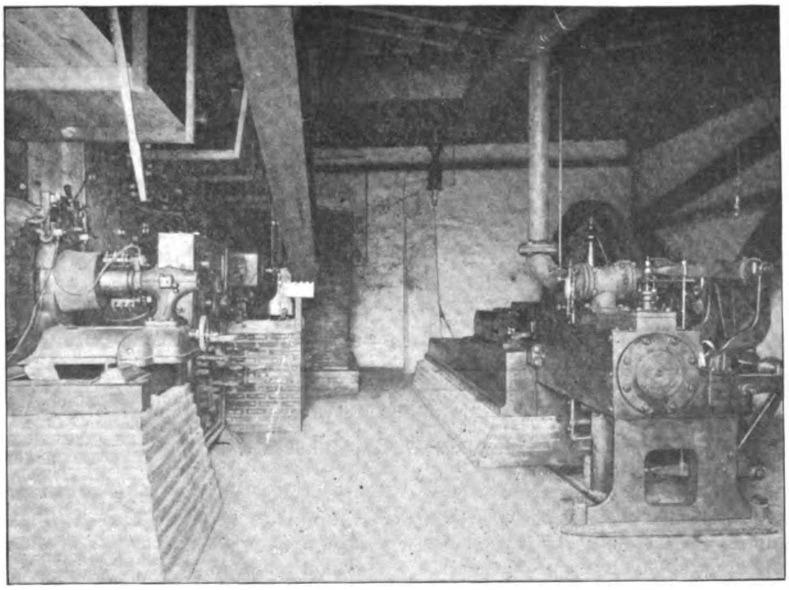


FIG. 2.—VIEW IN ENGINE ROOM, HIGH TENSION ELECTRIC STORAGE CO., SOUDERTON, PA.

It must be evident that the High Tension cell is peculiarly adapted to portable work. The company have recently placed on the market a carriage lighting battery and have also designed a large variety of types of batteries for special work such as for the use of physicians, batteries for lantern projection, and for general uses of all kinds. We may also add that a High Tension battery of the type described has been in actual operation lighting an apartment house in Philadelphia during the last two years.

The works of the company are situated at Souderton, Pa., and are thoroughly equipped for carrying on the company's work, and located directly opposite the tracks of the Reading Railroad so that its shipping facilities are of the best. A view of the engine room of the High Tension Electric Storage Company, of Souderton, Pa., is shown in Fig. 2. The offices of the High Tension Electric Storage Company are in the Heed Building, 1215 Filbert street, Philadelphia. Prof. N. H. Edgerton, inventor of the battery, is president of the company, and the following are the officers: Dr. Joseph H. Wilson, vice-president; A. M. Gissinger, secretary; J. K. Clenner, treasurer; J. B. Alderfer, general manager.

NEWS AND NOTES

Heavy Telephone Cable Laid Across the North River for the Use of the Government.

ONE of the strongest evidences of the great activity which now exists in the various departments of the Government are the large orders placed for electrical apparatus and the unlimited supply of submarine cables which have been ordered for immediate delivery. These cables will be used for various purposes such as the establishment of telegraphic and telephonic communication between the numerous coast defences and the wiring of mines and torpedoes which have been placed in several harbors or near fortifications. Cable factories have been running full force day and night for some time, and as soon as the cables are completed they are laid with the greatest dispatch. The extensive use which the Government is making of the telegraph and telephone lines has necessitated the companies owning these lines to lay additional cables and string more overhead wires in order to meet this sudden and urgent emergency. One of these companies has been the American Telegraph and Telephone Company, which only a few days ago accomplished the remarkable feat of stringing six overhead wires from Philadelphia to Washington in six days. The New York Telephone Company already have about fifty submarine cables joining the New York and Jersey shores, but in order to meet the increasing demand in its business and for the reasons given above, they have placed an order with W. R. Brixey for three additional submarine cables, one of which was successfully laid on April 15. The cable, which is one of the heaviest of that kind ever manufactured, is 4,850 feet long and weighs about 16 tons. It consists of 20 conductors of 3 strands each of No. 22 B. W. G. covered with ¼-inch Kerite insulation. These conductors are protected by 25 No. 4 B. W. G. steel armor wires and these are covered by a layer of jute and tar. The cable is about 2½ inches in diameter and its weight per mile is about ten times that of an ordinary ocean cable. The tug "Western Union, commanded by Captain G. T. Olmstead, left Pier 13, foot of Cortlandt street, New York, after the end of the cable had been made fast. The cable, which had been transported from the Brixey factory at Seymour, Conn., had been wound on a reel and placed on board of the tug at the Harlem depot of the N. Y., N. H. & H. R. R. To prevent the layers from sticking together, the cable had been covered with soapstone, and brass rings were fastened around it every 100 feet. One end of the cable had been passed through a "snatch block" fastened to the end of the boom, and as the tug slowly moved away from the dock the cable was paid out by revolving the drum on which it was wound, by means of a small engine. As soon, however, as the tug had moved out for some distance, the steam power was cut off and the cable was paid out at the rate of twelve miles an hour. Inside of six minutes the cable was laid and the remaining 600 feet were run beneath the Jersey City dock, known as Pier C, terminating in the new cable house of the New York and New Jersey Telephone Company. Here it was connected to the wires which had recently been run in the newly laid conduits, which will accommodate over two hundred wires. The laying of the cable was superintended by Mr. A. Kline, who has been connected with cable laying for over twenty-five years. Others who witnessed this interesting operation were Messrs. W. R. Brixey, Geo. F. Porter and G. C. Allen, Superintendent of Construction of the New York Telephone Company.

Preparations for War.

If the preparations going on elsewhere equal those in New York, electrical engineers are doing their share for the country. We have already referred to the splendid initiative of Captain Eugene Griffin, but he himself could not have wished more spirited and energetic seconding than has come from the New York Edison Co., of whose staff Mr. Arthur Williams has been specially active. We do not propose to go into details, any more than we did last week, but may simply say that the work done around the approaches to New York, by the volunteer electrical forces thus marshalled, promises the hottest kind of a time night or day, for any ship or fleet that noses up to our coast.

Rychnowski's Electric Fluid.

The following delightful item comes from London, dated April 15, where the scientists failed to intercept it: "A dispatch to the 'Daily News' from Vienna says that Sczcepanik, the inventor of the Fernseher, and his financial partner, Kleinberg, have gone to Lemberg to negotiate for the purchase of an invention of an electrician named Rychnowski, who claims to have discovered 'the electric fluid.' He calls it electroid. It is not identical with electricity. It is said that it produces light, causes Geissler tubes to show fluorescent rays, rotates objects in the air, produces whirlpools in water, kills bacteria, and performs other wonders. The correspondent rather unkindly adds that the invention has not as yet been scientifically examined."

Rules for Interior Wiring.

The Department of Public Buildings, Lighting and Supplies, of New York City, Henry S. Kearny, Commissioner, has just issued its new rules and regulations for interior wiring. They are admirable in every respect, and should do much to promote good work in the Greater New York, bringing it all up to the high standard set by Mr. Alex. Henderson, the Chief Inspector.

SOCIETY & CLUB NOTES

Fifth Annual Reception and Exhibition of the New York Academy of Sciences.

THE New York Academy of Sciences held its fifth annual reception and exhibit of recent progress in science in the American Museum of Natural History on April 13 and 14, 1898. On the evening of the 13th a reception was tendered to the members of the Academy and invited guests. During the evening of the 14th, members and their friends viewed the exhibits and in the evening there was a reception to the members of the Scientific Alliance, when a demonstrative lecture was delivered by Prof. Geo. E. Hale, on "The Function of Large Telescopes." This was preceded by an introduction by the president of the Academy, Prof. Henry F. Osborn, and by the president of the Museum, Morris K. Jesup, Esq. For a number of years the exhibits of the Academy have been noted for the great variety of scientific apparatus shown and the very interesting and popular demonstrations of scientific investigations. The exhibition this year was exceptionally instructive, and of the numerous exhibits the following deserve special mention: In the department of anatomy, in charge of Geo. S. Huntington and Jos. A. Blake, radiographs showing the topographical relations of the

trachea and bronchi to the thoracic walls. In the department of chemistry, in charge of Dr. Charles A. Doremus, experimental illustrations on liquid air and its properties were given by Mr. Charles E. Tripler, which were highly appreciated by a large number of interested visitors. Prof. Morris Loeb and Mr. J. H. Shipley exhibited a method of preparing pure tellurium and some of its compounds. In the department of electricity, in charge of Mr. Geo. F. Sever, the following apparatus was exhibited by Prof. M. I. Pupin: A thirty-inch spark induction coil, built by L. R. Lovejoy; electrical oscillators for selective signaling; an optical telephone; bridge for measuring phase retardation between current and electromotive force. Mr. J. G. Biddle exhibited some of his improved electrical apparatus, such as the Willyoung induction coil, and direct reading potentiometer; the Rowland electro dynamometer; and the Rosa curve tracer for alternating current curves. Mr. W. J. Clarke showed his apparatus for the transmission of signals at a distance without wires in actual operation, and Mr. G. C. Halk exhibited the following apparatus for Queen & Co.: The Queen Acme testing set; a complete twelve-inch X-ray outfit, with self-regulating tube; various styles of galvanometers and a self-focusing lamp, built by Messrs. Baker & Fox, which has many commendable features. Other interesting exhibits were shown in the departments of ethnology; experimental psychology; geology; mineralogy; philology, photography and physics, which was in charge of Prof. Wm. Hallock. In this department much novel and interesting electrical measuring apparatus was shown, as well as some photographs showing the penetrability, the path and the refraction of Röntgen rays.

President Insull to Attend.

Mr. Samuel Insull, president of the National Electric Light Association and of the Association of Edison Illuminating Companies, was in New York last week. He takes a very lively interest in the progress of the Exhibition, and has informed the management that he will take the utmost pleasure in coming on specially from Chicago, in behalf of those two representative bodies, to participate in the opening exercises on May 2. These exercises as now arranged promise to be of an unusually striking and interesting character.

The Coming Telegraph Tournament.

The telegraph tournament judges held a meeting at the Astor House on April 13, among those present being Fred Catlin, T. J. Smith, J. B. Taltavall, H. W. Pope, George H. Guy, A. E. Sink, E. A. Leslie, W. D. Weaver, P. T. Brady, P. B. Delany, S. F. Austin, T. R. Taltavall and William Maver, Jr.

The meeting was called to order by Mr. Catlin, who was elected chairman. J. B. Taltavall was elected secretary. After some discussion it was decided that the conditions to govern the judges in their decisions, as printed in the circular which has been widely circulated, sufficiently covered the ground.

An executive committee was then appointed to take care of all matters embraced in the duties of the judges.

The executive committee, consisting of Fred Catlin, A. E. Sink, T. J. Smith, P. B. Delany and J. B. Taltavall, held a meeting immediately after the judges adjourned. Mr. T. J. Smith was appointed a committee to arrange for suitable phonographic records, and Mr. P. B. Delany to provide apparatus for chemical or other records not phonographic.

The executive committee then adjourned, to meet on April 21.

Mr. A. E. Marr, of the Associated Press, an exceptionally good code operator, has been added to the list of judges.

The Smith-Premier Typewriter Company state that those living at a distance who desire to use their machine in the contests need not bring their typewriters with them to New York. Mr. W. H. Durphy, the New York manager of the company, is prepared to furnish all comers with typewriters.

Mr. Fred E. Burnell, of New York, proposes to enter one or two events in the tournament, more with the idea of demonstrating the fact that telegraphers' paralysis is a curable disease, and giving telegraphers a practical demonstration of his complete cure by electricity itself.

Friday evening, May 13, and Saturday afternoon and evening, May 14, are the dates on which the tournament will take place.

Offices of the Exhibition.

Mr. Marcus Nathan, the general manager of the Exhibition, has moved his offices from 15 Cortlandt street, to Madison Square Garden, where he can now be found directing and managing matters. Annexes of the Garden to be used for the Exhibition, have already passed into his control, and the huge main hall will be turned over to him at midnight on April 25. The following week will see some great work done in the transformation of Buffalo Bill's prairie and desert scenes into the dazzling spectacles of electricity's triumphs.

The Stieringer Fixture Litigation.

It appears by papers filed in the Supreme Court on April 16, 1898, that the suit brought by Luther Stieringer against Richard N. Dyer and George Maitland for an accounting has been settled. Under the judgment which Mr. Stieringer had obtained in the action, the patents had been transferred to Mr. George Flint Warren, Jr., as receiver, and he had assumed management of the business under the patents. It seems that Mr. Stieringer has secured recognition of his claims on this settlement to the extent of some $15,000 to date, and a continuing increased interest in the future income from these patents. The settlement also involves the withdrawal of an appeal which had been taken and was about to be argued.

Waiting and Wondering.

The general conditions of the country may be said to have followed with closely sympathetic rise and fall the changes in the aspect of our international quarrel. The uncertainty of it all is not doing much good to anybody. If there should be war, the expenditure of large sums of money would stimulate trade, even though artificially. If there is peace, industry will at once expand in normal channels. But the long doubt and anxiety tend to slacken energies in all lines.

During the past week 5,076 shares of Western Union were sold at about 85½, a net loss of ¼. General Electric, after sales of 5,045 shares, closed 1½ lower at 31¼. All local electrical stocks were dull. In Boston, American Bell Telephone closed the week at 250.

WILLIAMS ELECTRIC CO., of Cleveland, O., has been incorporated with a capital stock of $25,000 by J. A. Williams, W. G. Meade, F. J. A. Keller, B. J. Chamberlin, and G. Gebhard.

J. JONES & SON will move on May 1 from their present quarters to new ones. They will occupy the entire building No. 64 Cortlandt street, giving them four stories, a liberal allowance of space for the factory and ample room for the handling and selling departments. As a matter of fact, the firm will just about double their space for manufacturing, but this is needed to keep pace with the increase in the demand for their goods. Mr. E. A. Lowe, their manager, informs us that they have recently booked an order from the U. S. Government for shipment to one of the Southern ports of a general equipment of electrical apparatus. It will require four railroad cars to transport the material.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued April 12, 1898.

Alarms and Signals:—

ELECTRIC BLOCK SYSTEM. F. Burger, Ft. Wayne, Ind., 602,208. Filed Aug. 2, 1897. Employs a switch-operating magnet whereby when a car enters a section the corresponding magnet is energized to open the switch and break the circuit controlling the rear section; and when the trolley leaves the section and enters a succeeding section, the trolley operates the switch to restore it to its normal position.

Batteries, Secondary:—

SECONDARY BATTERY. F. W. Schneider, Triberg, Germany, 602,172. Filed June 10, 1897. Consists of an insulating and supporting frame especially adapted for horizontal—for instance, tubular or trough shaped—secondary batteries.

STORAGE BATTERY. G. A. Washburn, Cleveland, O., 602,176. Filed May 22, 1897. An electrode having on each side a series of groups of concentric ring shaped projections of uniform cross section, and equally spaced at all points to hold active material between them and standing out above the adjacent surface of the plate and a hole centrally through each group.

Batteries, Primary:—

GALVANIC BATTERY. W. Rowbotham, Birmingham, England, 602,362. Filed Dec. 16, 1896. A hermetically-sealed electric battery having a depolarizing liquid compartment and the liquid expansion chamber located in juxtaposition to one another, and tubular carbon elements communicating with the expansion chamber.

Conductors, Conduits and Insulators:—

PROCESS OF FABRICATING METALLOCERAMIC RESISTANCES. L. Parvillée, Paris, France, 602,227. Filed Nov. 13, 1897. Consists in mixing a metallic powder with extraneous bodies such as quartz, kaolin, clay or feldspar and with a flux, subjecting the whole to pressure and then firing the same.

Distribution:—

ELECTRIC TRANSFORMER. L. Gutmann, Pittsburg, Pa., 602,218. Filed Oct. 31, 1890. Comprises a core element consisting of a plate of magnetic material having two or more recesses causing extensions, and a strip adapted to interlock with the extensions.

Dynamos and Motors:

DYNAMO FOR ELECTRIC CAR LIGHTING SYSTEMS. E. J. Preston and A. B. Gill, London, England, 602,182. Filed Feb. 25, 1895. Comprises a dynamo connected by a pulley to the axle of the car, means whereby the dynamo is drawn away from the axle to give the belt the proper tightness up to a certain speed, and further means to draw the dynamo toward the axle when the speed exceeds the pre-determined limit.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. E. Weber, Paris, France, 602,380. Filed Sept. 11, 1897. Comprises a frame and electromagnet, a magnetic disc in the field of the magnet, a brake for the disc, an armature co-acting with the magnet and controlling the brake, the magnet serving to retard the revolution of the disc, and a carbon holder having connection with the disc.

ELECTRIC ARC LAMP. J. Mueller, Cleveland, Ohio, 602,404. Filed Aug. 27, 1897. Feed mechanism for open arc lamps.

Miscellaneous:—

ELECTRIC CORD ADJUSTING DEVICE. F. N. Lawton, Summit, N. J., 602,235. Filed April 5, 1897. Consists of a metal wire, having a smooth curved exterior surface, bent into a series of successive loops arranged in the same plane, and having a layer of insulating vitreous enamel thereon.

PROCESS OF AND APPARATUS FOR ELECTRODEPOSITING. E. L. Dessolle, Epinay Sur Seine, France, 602,212. Filed Aug. 25, 1897. Consists in first saturating the surface of the cathode, which is of metal capable of occluding hydrogen, with hydrogen, electrocoating the cathodes with metal, and then stripping the deposit from the cathode in order to prevent the adherence of the metallic deposit to be afterwards made.

SUSPENDING BATTERIES ON CARRIAGES. R. T. D. Brougham and W. C. Bersey, London, England, 602,302. Filed Dec. 13, 1897. Comprises a box, springs suspending the box from the carriage frame and a rod pivoted at one end to the frame and at the other end to the box.

MANUFACTURE OF REFLECTORS. S. O. Cowper-Coles, London, England, 602,306. Filed June 10, 1897. Consists in applying to a prepared mold, a coating of silver or other suitable metal, then depositing thereon electrically a backing of base metal, and then separating the reflector from the mold by heating the same in a water-bath.

SYSTEM OF ELECTRICAL PROPULSION FOR VESSELS. J. J. Heilmann, Paris, France, 602,325. Filed Dec. 3, 1895. Comprises one or more propellers in each vessel rotated by means of electric motors supplied with current from an electrical generator, which is also carried upon the same vessel.

Railways and Appliances:—

SUPPLY SYSTEM FOR ELECTRIC RAILWAYS. P. J. Pringle, London, England, 602,142. Filed Oct. 26, 1896. Sectional surface contact system.

TRACK WELDING. R. Ryre, Johnstown, Pa., 602,284. Filed Sept. 22, 1897. Combines with the terminals spanning the ends of the rails, dies and contacts, detached from the terminals, and secured directly to the sides of the rails, and an upsetting tool surrounding the terminals and secured to both rails.

CONDUCTOR AND CONTACT DEVICE FOR ELECTRIC RAILWAYS. A. S. Kortz, Springfield, O., W. P. Allen, Chicago, Ill., and O. S. Kelly, Springfield, O., 602,336. Filed May 28, 1897. A contacting device for third-rail electric railway systems comprising a suitably formed body portion having a shoe, a block pivoted thereto, and a resilient supporting piece connected with the block.

Switches, Cut-Outs Rheostats, Etc.:—

AUTOMATIC DEVICE FOR REMOVING RESISTANCES IN STARTING ELECTRIC MOTORS. G. H. Whittingham, Baltimore, Md., 602,413. Filed Sept. 9, 1897. Embodies a centrifugal governor acting to cut in the resistance when the proper speed limit is reached.

Telephones:—

TELEPHONE TRANSMITTER. H. E. Shreeve, Boston, Mass., 602,174. Filed Aug. 26, 1897. Comprises a vibratory diaphragm, and front and back electrodes both mounted thereon, the former being rigidly, and the latter elastically attached thereto, and a variable resistance medium composed of carbon.

PERSONAL

Mr. E. J. Wessels.

The brilliant success achieved by Mr. Wessels in advertising and forcing on a reluctant market a commodity whose genuine merit was only obscured by its high price, led many of his friends to believe that he would ultimately step boldly into the publishing field, and this he has now done. After negotiations for the purchase of one of the oldest and most influential religious journals in this country, Mr. Wessels has put into force one of his pet ideas in the publication of "The Universe," a weekly newspaper of current events, for the young and the busy. It has proved an instantaneous and stunning hit. The chief editor is Mrs. Sydney H. Rosenfeld, whose charm and trustworthiness as a historian of absolute impartiality is well known; and with her are associated many well known people, all of whom tell the news of the day in their respective fields clearly, simply, and plainly, but with literary deftness and with the aid of frequent illustrations. The paper is published at 96 Fifth avenue, New York; 5 cents per week or $2 per year. We can most warmly commend this antidote to yellow journalism to all our readers. It is said that no magazine has ever picked up so quickly such a large subscription list as the clever and solid "Universe." Mr. Wessels bids fair to become one of the best known publishers of good literature in this country.

Mr. Albert A. Cary.

This well known mechanical engineer, so long associated with the technical side of the Abendroth & Root Co., in the development and sale of their Root boiler, has recently taken a very interesting step in severing that connection in order to devote his whole time and all his energies to the Monarch engine stop and automatic speed limit, made by the Monarch Mfg. Co., all of whose product will be exclusively handled by himself and his agents throughout the country. We shall later have an opportunity to illustrate and describe this ingenious attachment in its perfected form. An engine equipped with this device, has one more first-class engineer to look after it, and the lessening of danger and the minimizing of damage if trouble occurs, have already been shown in scores of instances, to be simply wonderful. As an old steam engineering expert, Mr. Cary stands at the head of his profession, and it is significant that he should devote his great abilities to the introduction of this appliance. Friends in every quarter will wish him success.

Mr. E. R. Knowles.

Few men are so well known in the electrical field as Mr. Edward R. Knowles, the electrical, civil and mechanical engineer, and the trade will be interested to learn that he has become identified with the Sprague Electric Company, where he will have entire charge of their Power Motor Department. Mr. Knowles is so well known that it is almost superfluous to say much about him. He is a Californian by birth, but his work and life have been almost entirely in the East, where as an engineer for electrical installations, and later in his specialty of supplying electric motive power to all classes of machinery, and as consulting engineer for the New York and Brooklyn Bridge Company, New York "Journal," and scores of other large corporations, he has attained a very enviable reputation. Mr. Knowles's career as an electrical inventor, and in the developing, perfecting and rendering commercially successful the ideas of others, has been more than noteworthy, and his all round reputation and ability will prove of great value to the Sprague Company. His engagement furnishes additional evidence that the Sprague Company is determined to have the best men in the right place, and both the Sprague Company and Mr. Knowles are to be congratulated on their new alliance.

TRADE NOTES & NOVELTIES

Construction of General Electric Slow and Moderate Speed Generator Armatures.

IN the construction of the armatures of all direct current generators and motors built by the General Electric Co., especial care is taken to produce as perfect and durable a part

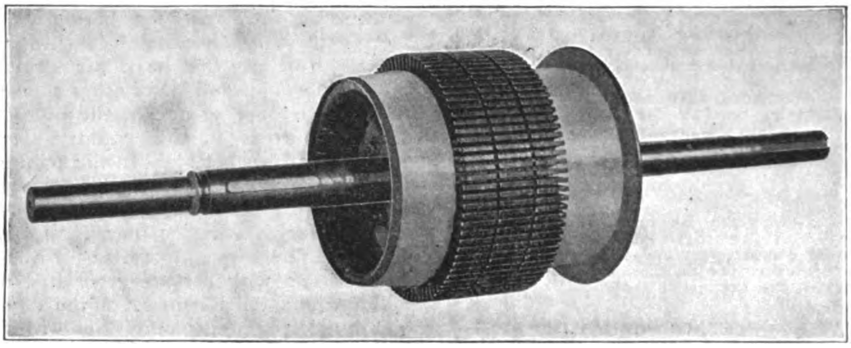

FIG. 1.—IRON CORE OF G. E. ARMATURE.

as possible, without sacrificing any detail essential to efficiency and perfect operation. New ideas have been incorporated, and old and tried features retained; the wire and iron must reach a certain standard of excellence or be rejected; each step in con-

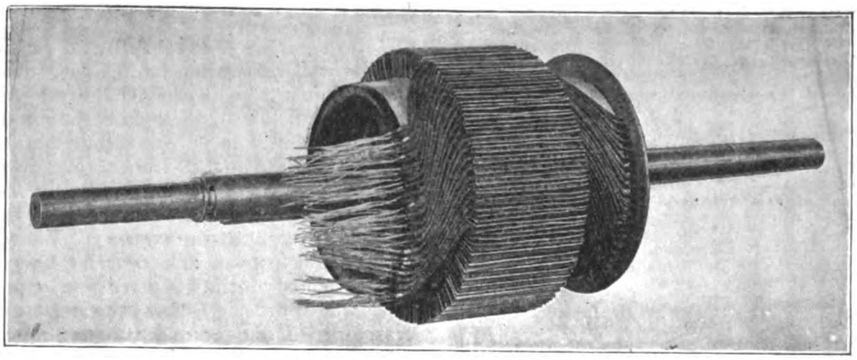

FIG. 2.—METHOD OF APPLYING COILS ON G. E. ARMATURE.

struction is carefully inspected and the completed armature is subjected to a test many times more severe than the severest conditions which would be met with in actual service. Nothing is left to chance.

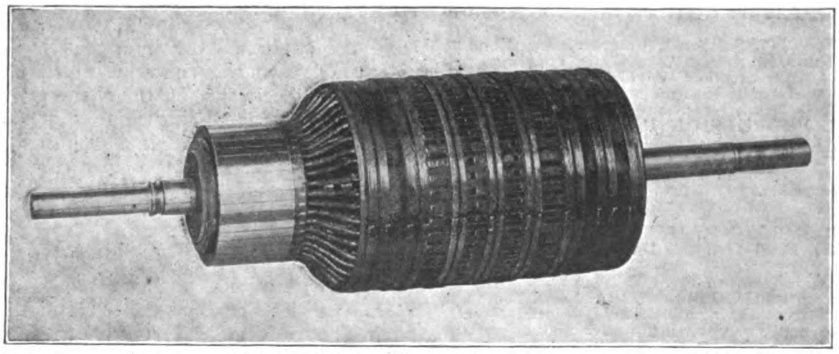

FIG. 3.—COMPLETED G. E. ARMATURE.

In the armatures of the new type of slow and moderate speed direct current generators and motors these characteristic features are strikingly apparent. The completed armature, shown in Fig. 3, is a slotted body of barrel shape, so built that no part is susceptible to movement or vibration. There are no sharp bends to the wire over sharp metallic edges, and each coil is so laid on the core that the outer periphery of the core itself affords it complete protection from mechanical injury.

The spider castings holding the slotted sheet iron laminations are extended into cylindrical flanges at both ends, shown in Fig. 1. The coils previously shaped on a form are laid in the slots, and the ends lie along these flanges at each end of the spider instead of being bent down sharply toward the shaft, see Fig. 2. The coils are formed and insulated before assembling on the core in order that, before application in their final position, they may undergo a careful test, and no coil is used that does not emerge from this with insulation intact. The insulation used is similar to that employed in the G. E. railway motors, and in the operation of these, has given ample proof of its excellent qualities. It is tough, impervious to moisture, and practically indestructible, except under abnormal overload, while it affords high resistance to puncture, rendering injury from lightning extremely improbable. The insulated coils are laid in place in insulated slots in the core and are simply pressed home. The advantage of this method compared with that employed on an armature with the wire wound directly upon it, is obvious.

The cylindrical winding has many positive advantages. A very large radiating surface is provided for the conductors, and this

combined with special air ducts for the passage of currents of air through the core from the interior outwards, tends to keep the armature cool; the length of wire is reduced to a minimum and consequently the losses due to armature resistance are also reduced, while the efficiency of the machine is greatly increased. The complete coil being formed separately and then applied, any one or more coils may readily be removed and replaced.

The coils are firmly secured in the slots on the cylindrical extensions, so that no part can move or vibrate. Indeed, rigidity is one of the most important advantages of the cylindrical winding, since without motion of the parts neither injury nor deterioration of the insulation is likely to occur. The ends of the coils are curved down to the commutator, and the connections are so arranged that open circuiting is impossible. The illustrations show the three different steps in the construction of a General Electric slow and moderate speed generator armature from the completed core to the completed armature.

New Battery Motors of the Kent Electric Manufacturing Co.

THE Kent Electric Manufacturing Company, of Worcester, Mass., who lately have been putting drum armatures into battery motors, are now putting on the market a new motor, which embodies many commendable features and differs greatly from most makes of battery motors. It is very compact, and is of ample proportion and weight, thus giving it great strength

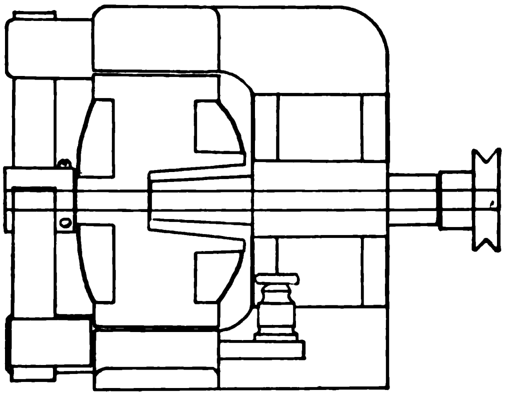

FIG. 1.—CROSS-SECTION OF KENT BATTERY MOTOR.

and capacity. The cross section of the motor shown in Fig. 1 below gives an excellent idea ot its construction.

It has but one bearing, 3 inches long. This bearing is a portion of the field magnet frame at a point where the magnetism is neutral. Thus, the shaft can never get out of alignment or bind, and there are no bearings to adjust. Another advantage which will be appreciated by motor users is that there is no bearing on the commutator end, where the oil will run on to the commutator and prevent the brushes from making good electrical contact. The binding posts are conveniently located by the side of the field coil, and are entirely out of the way.

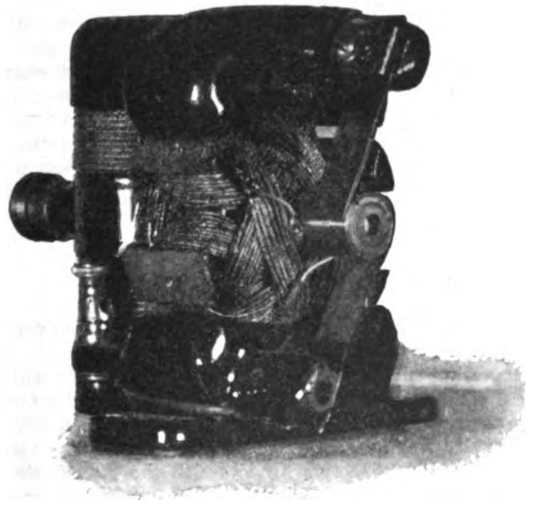

FIG. 2.—KENT BATTERY MOTOR, TYPE C.

This motor is constructed in three sizes, the No. 1, in which the armature is 2 inches in diameter, the No. 2 in which the armature is 2½ inches in diameter and the No. 3 in which the armature is 3½ inches in diameter. These motors are equipped with the company's regular drum armature, which is claimed to do away with the rattling common to three-pole a-matures, as it is not pulled from side to side by uneven distribution of magnetism. This motor, shown in Fig. 2, is designated as Type C.

New Chapman Voltage Regulator.

THE new Chapman voltage regulator consists of three essential parts, viz.: A set of resistance coils to be inserted or removed from the field magnet circuit of the generator to be regulated; a working solenoid to do the work of inserting and removing the coils from the circuit; and an auxiliary solenoid to determine the movement of the working solenoid. The resistance coils are made of German silver, and the size of wire used is such as will afford ample capacity to control the field current of the generator for which it is constructed. The resistance coils are connected to a series of copper segments placed in a horizontal row, and having a contact slider arranged to move over their surface. This contact slider is operated by being mechanically connected to the moving core of the working solenoid. The working solenoid consists of two differentially wound coils of wire placed on a brass tube, one at each end of the tube, and the whole placed in a horizontal position. The middle portion of the tube is left vacant. Inside of the tube is fitted a soft iron plunger somewhat shorter than the distance through the two coils; at the centre portion of the plunger a rod is attached which passes out through a longitudinal slot cut in the vacant portion of the tube. The contact slider above described is attached to this rod and so moves with it and with the iron plunger. In order to prevent too quick a movement of the plunger a very simple and ingenious retarding device is used, in which the moving iron plunger is made to serve the purpose also of an oil pump. From one end of the brass tube to the other a small pipe is connected having a hand valve in it, to regulate the flow of oil. The two ends of the brass tube together with its connecting pipe are completely filled with oil and closed up tight. The movement of the iron plunger toward either end can then take place only as it displaces this oil and causes it to move through the pipe and to the other end. The rapidity of this movement can be very finely adjusted by means of the valve above described.

The force tending to move the iron plunger depends on the balancing of oppositely wound coils against each other, and this balancing is determined by the action of the small auxiliary solenoid, whose only work is to cause one or another of two platinum pointed screws to make contact with the brass lever supporting its core. Contact with one screw causes perfect neutralization of the differential coil at one end of the working solenoid and so disturbs the balance; and causes the plunger to move toward the other coil. Contact with the other screw causes neutralization of the coil at the other end and a movement in the other direction. The small solenoid may be wound to suit a variety of purposes, any one of which may be required in fulfilling the demands of station regulation. It may be wound with a simple fine winding to be connected as a shunt across the lines to be regulated, and in this case it will secure constant potential regulation at the point of attachment to the line. Or, secondly, it may be wound with a fine winding as before and also with a coarse winding. The fine winding is connected as a shunt to the line and the coarse winding is in series with the line. In this case it will regulate for constant potential at some distant point on the line which may be predetermined by the setting of an adjustable compounding switch, provided as a part of the regulator. Or, thirdly, the small solenoid may be wound with a single coarse wire placed in series with the line. In this latter case it will secure regulation for constant current in the lines. But whatever be the nature of the regulation, the small solenoid will perform its duties with an accuracy as close as 1 per cent. above or below the normal, and is adapted to either direct or alternating currents. Alternating currents are especially capable of close regulation by this instrument, as the slight jar incident to current flow through the small solenoid almost entirely eliminates the element of friction at the pivots of the lever supporting the core, and it will easily recognize a change of ½ a volt on a 110-volt circuit. An illustration of the device is shown in our advertising pages.

Eugene Munsell & Co.

Eugene Munsell & Co., of New York and Chicago, are enjoying an excellent trade in their India and Amber "Mica" segments for railway motors. Several heavy orders have recently been received, one of which was probably the largest ever taken for "Mica" segments from an electric railway. It consisted of more than 800 pounds of the India and Amber segments.

The firm carry a large stock of "Mica," both in the sheet and cut to size; and have unequaled facilities, both at New York and Chicago, for executing orders promptly. They will take pleasure in sending samples for trial to any electrical manufacturer, repair concern, or street railway who may write them requesting such samples.

Sprague Elevators for St. Louis.

One of the latest electric elevator contracts awarded the Sprague Electric Company, is for an outfit of ten machines for the Commerce Realty Building, in St. Louis. Says a St. Louis contemporary: "This installation represents a distinct advance in St. Louis in modern installations of this character, and its performance will be watched with interest." The St. Louis order is but one of a large number of out-of-town contracts recently awarded the Sprague Company.

Large Orders For Card Motors.

The Card Electric Company, of Mansfield, O., report the following recent orders for their power, lighting and plating apparatus: One 225 k. w. generator to M. A. Bradley, Cleveland, O.; two 30 h. p. motors to Raton Coal & Coke Co., Raton, N. M.; one 100 k. w. direct connected generator and one 5 h. p. motor to the Cleveland Shipbuilding Co., Lorain, O.; two 30 k. w. generators to A. A. Gardener, Myers, Fla.; one 75 k. w. generator, one 50 h. p. and one 15 h. p. motor to A. Trostel & Son, Milwaukee, Wis.; two 20 h. p. motors to the Cambridge, O., Iron & Steel Co.; one 40 k. w. direct connected generator to Herman Zohrlant Leather Co., Milwaukee, Wis.; one 30 h. p. and one 15 h. p. motor to Chicago City Ry. Co.; eight electric plating dynamos to Bennett & O'Connell, Chicago, Ill.; one 10 h. p. elevator motor to Voegle & Dinning, Mansfield, O.; one 100 k. w. direct connected generator to Ohio & Pennsylvania Coal Co., Cleveland, O.; one 15 k. w. direct connected generator to Wadsworth Salt Co., Wadsworth, O.; one 20 k. w. generator and one 5 h. p. motor to P. H. Trout, Jr., Stanton, W. Va.; one 7½ h. p. and two 5 h. p. elevator motors to J. H. Reedy, Cincinnati, O.; one 15 h. p. motor to Wm. Mullens, Davenport, Iowa; one 100 generator and one 100 h. p. motor to Harter Milling Co., Fostoria, O.; one 30 k. w. direct connected generator to J. H. Wade, Cleveland, O.; one 150 k. w. generator to Elwood, Ind., St. Ry. Co.; one 75 k. w. direct connected generator to J. P. & J. S. Jett, Carrollton, Ky.; one 25 h. p. motor to Johns & Co., Cleveland, O.; one 15 h. p. motor to Jacob Dold Packing Co., Buffalo, N. Y.; one 15 h. p. motor to National Carbon Co., Cleveland, O.; one 15 k. w. generator to Cincinnati House of Refuge; one 40 k. w. generator to Phalanx Silk Mills, Jersey City, N. J.; one 15 k. w. direct connected generator to U. S. Government Light House, Detroit, Mich.; one 50 k. w. generator and one 20 h. p. motor to Wolverene Mfg. Co., Detroit, Mich.; one 7½ k. w. generator to McCullen & Cook, New Orleans, La.; one 7 k. w. generator to Hawee Bros., Springfield, Mass.; one 20 k. w. generator and one 10 h. p. motor to A. J. Root, Medina, O.; one 25 k. w. generator to Flint & Lomax, Denver, Col.; one 40 k. w. direct connected generator to Kieffer & McArthur, Mt. Clemens, Mich.; one 10 h. p. motor to John Christie, Green Bay, Wis.; one 10 h. p. motor to W. S. Carter, Jackson, Mich.; one 10 h. p. motor to Keelyn & Smith, Milwaukee, Wis.; one 3 h. p. motor to C. F. Ganshow, Saginaw, Mich.; one 3 h. p. motor to W. E. Bridegram, Reading, Pa.; one 7½ h. p. elevator motor to Tracy & Avery, Mansfield, O.; one 30 k. w. direct connected generator, one 15 k. w. belted genrator and one 20, one 10, one 7½ h. p. motors to Deen & Schaum, Lancaster, Pa.; one 5 h. p. elevator motor to H. S. Long, Marion, O.; one 15 h. p. generator to J. S. Turner, Springfield, S. D.; one 35 h. p. motor, Citizens Elec. St. Ry. Co., Light & Power Co., Mansfield, O.; two 4 k. w. generators to Geo. Haucke, Springfield, O.; one 40 k. w. generator, two 10 h. p. and one 5 h. p. motor to the Ohio Brass Co., Mansfield, O.; one 7½ h. p. elevator motor to Eaton & Prince, Chicago, Ill.; one 20 k. w. generator to C. I. Case, Cleveland, O.; one 5 h. p. motor to T. P. Ford, New York, N. Y.; one 10 h. p. motor to Turner Engineering Co., Marion, O.; one 3 h. p. motor to Speers & Winfield, Youngstown, O.; one 5 h. p. motor to J. F. Wider & Son, Saginaw, Mich.; one 25 h. p. motor to Ship Owner's Dry Dock Co., Cleveland, O.

Sprague Electric Co. Dividend.

The Board of Directors of the Sprague Electric Company have declared a dividend of 3 per cent. on the preferred stock payable on May 2 to shareholders of record of the 18th instant.

CATALOGUES.

The Pelton System of Power.

AN exceptionally useful, instructive and artistic catalogue has recently been issued by the Pelton Water Wheel Co., of San Francisco and New York. It contains a hundred pages, is richly illustrated, and may be called a text book on hydraulic engineering. The introductory chapters of the book contain valuable information on the use of water power for transmission purposes and the means for utilizing such powers to good advantage. Among the numerous tables presented in the book, those giving the horse power, cubic feet, miner's inches and revolutions for any size wheel and head in feet, tables for calculating the horse power of water, loss of head in pipes by friction and weir measurements, deserve special mention. A list of 125 installations, which vary exceptionally as to head and variety of service, is given, and numerous plants are described in detail. As stated above, the catalogue is profusely illustrated with halftone cuts to show the apparatus of the company, and also with a large number of line cuts to illustrate the text, which is so admirable a feature. The company is to be congratulated on the merits of its literary production.

Test of the Power Plant of the Brockton Street Railway Company.

The above is the title of a very complete and instructive pamphlet issued by Messrs. Stone & Webster, electrical experts and engineers, 4 Post Office Square, Boston, Mass., which contains the results of tests they have made for the purpose of determining whether the specifications for the extension of the Brockton Street Railway Co.'s power plant had been properly met. The pamphlet contains the details of tests to obtain the evaporative performance, commercial horse power and rate of combustion and evaporation of the boilers, speed regulation, power and efficiency of the engines, and the efficiency, capacity and temperature under load of the generators. A number of illustrations and curves accompany the report and the results show that the requirements of the specifications had not only been met, but had been surpassed, which certainly reflects much credit on the engineers in charge of the work.

Spague Electric Company.

The high class catalogues issued of late by the Sprague Electric Company, 20 Broad street, New York, have already won for that enterprising firm much well deserved praise and commendation. The typographical work and general appearance of the literature issued by this company is of the highest class and does justice to the excellence of their products. Two catalogues, one entitled "Electric Motors and the Art of Printing," the other illustrating the Lundell fan motors, have just reached our office, and are certainly masterpieces of the engraver's art. They are, one might say, text-books on the subject of which they treat, and the text is complete in every particular, including the illustrations. Types of Lundell fan motors are described, principal among which may be mentioned the column fan motor with umbrella stand, which will certainly commend itself to the general public.

Eastern Electrical Supply Company.

The Eastern Electrical Supply Company, of 26 Cortlandt street, New York, have just issued a very neat and attractive descriptive catalogue and price list of electrical supplies which they manufacture. The list includes a great variety of electrical supplies such as cut-outs, ceiling rosettes, sockets, push and knife switches, panel boards, wire guards, chandeliers, carbons, incandescent lamps, measuring instruments, fan motors, bells and fire alarm boxes. The catalogue is profusely illustrated, and has a very complete index.

Holtzer-Cabot Electric Company.

A very complete and handsome descriptive catalogue of magneto bells, power generators, desk telephone sets, interior telephones, telephone annunciators, receivers, transmitter arms, and other telephone apparatus, has just been issued by the Holtzer-Cabot Electric Company, of Boston, Mass. The catalogue contains a large number of illustrations, showing the high grade goods manufactured by this company, and they advise their patrons to investigate well before they purchase, for experience gained by mistakes is very costly. A new motor and dynamo catalogue is now in preparation, and will be issued shortly. A number of circulars devoted to general electrical supplies and fan motors have also been issued of late, which will be sent to the trade upon application.

Armington & Sims Company, Providence, R. I.

These well known engine builders have just issued a very handsome catalogue of the great variety of sizes and types of engines, which they manufacture to meet the requirements of any service. The 1898 pattern Armington & Sims high speed engine embodies among the most important improvements: Adjusting cylindrical or piston valve, the Rites inertia governor, a very efficient oiling device, all of which are illustrated and described in detail. The catalogue contains tables and price lists of the various types of engines; condensing, non-condensing, simple, compound, and cross compound, and the second portion of the catalogue is devoted to a description of direct-connected engines. Over 5,100 Armington & Sims engines are now in successful operation, which is convincing evidence of their superiority, the result of thorough methods and careful attention to details in every department.

The Queen Acme Testing Set.

The chief advantages of this well known instrument manufactured and sold by Queen & Co., Inc., 1010 Chestnut street, Philadelphia, Pa., are the accuracy attainable and its portability, its extremely wide range of measurement and its freedom of error or derangement. The instrument is the result of the continual effort on the part of the company to incorporate these essential features in a thoroughly practical form of resistance box, ranging from one hundredth of an ohm to one megohm, which can be accurately measured. The coils are wound with platenoid wire carefully seasoned; there are sixteen coils in all, their total resistance being 11,110 ohms. The galvanometer is of the well known D'Arsonval type, and the battery consists of six chloride of silver cells. The company has recently issued a catalogue which fully describes this instrument and methods of using it, and gives a complete list of other catalogues issued by Queen & Company.

Colt & Co.'s Lantern Slides.

J. B. Colt & Company have earned for themselves so enviable and well deserved a reputation that their timely action of preparing a series of current topic lantern slides is not at all surprising. This latest series contains such subjects as The Maine Disaster, Cuba and Her War, Vessels and War Ships of Spain and the United States, Sailor Life in the United States Navy, and the Manners and Customs of the Cubans. A catalogue illustrating a great variety of these timely subjects, enumerating in all 455 slides, must certainly be of timely interest and great value to lecturers and societies. The executive offices of the firm are at 115-117 Nassau street, New York, and after May 1 at 3-7 West Twenty-ninth street. Branch offices are located at 189 La Salle street, Chicago, Ill., and 131 Post street, San Francisco, Cal.

The Murray Iron Works Company's Tubular Boilers.

The many advantages of the high pressure modern tubular boiler are ably set forth in the catalogue of the Murray Iron Works Company, Burlington, Iowa. Five styles of boilers manufactured by this company are illustrated and give the reader a good general idea of the product of this well known concern.

ADVERTISERS' HINTS

THE WHEELER REFLECTOR CO., Boston, Mass., invite their customers to specify where they want the light and guarantee to send them a reflector to suit each condition.

THE CROCKER-WHEELER ELECTRIC CO., 39 Cortlandt street, New York, after having considered the requisite features of a motor for elevator service have designed and introduced one which they are sure will prove an unbounded success.

THE WALKER CO., Cleveland, Ohio, are advertising trolleys.

THE ELECTRICAL EXHIBITION CO., 15 Cortlandt street, New York, have but little space left for sale, and advise those who wish to secure it to do so at once, as in a very few days every inch of it will be sold.

THE SHELBY ELECTRIC CO., Shelby, Ohio, advertise incandescent lamps of all voltages and candle powers.

THE STANDARD PAINT CO., New York, have found it necessary to open an office in Hamburg, Germany, to take care of their constantly increasing business in that country.

VISITORS TO THE EXHIBITION will find the Gilsey House and the Sturtevant House both within convenient distance of the Madison Square Garden.

THE KEYSTONE ELECTRIC CO., Erie, Pa., are advertising their type "H" enclosed steel motors which they state are fireproof, waterproof, slow speed and noiseless.

THE CHAPMAN VOLTAGE REGULATOR has given great satisfaction in many plants, if we judge by the many testimonials we have seen regarding its efficiency. Another feature worth considering is the saving in attendance. The Belknap Motor Co., of Portland, Me., are the manufacturers.

THE LYNN INCANDESCENT LAMP CO., Lynn, Mass., offer to buy up burned-out lamps at three cents each.

THE NORDEN ELECTRIC CO., 145 West 28th street, New York, are ready to assist exhibitors in getting ready their exhibits. They undertake wiring construction work, supply electric signs, incandescent lamps, arc lamps, sockets, switches, etc.

INTERIOR TELEPHONES are advertised by the Allen-Hussey Co., 213 Randolph street, Chicago. They issue illustrated descriptive circulars.

THE ELECTRIC STORAGE BATTERY CO., Drexel Building, Philadelphia, Pa., state that a decrease in the cost of production and an increase in earning power has been brought about by the use of the "Chloride Accumulator" in central lighting and power stations.

THE HIGH TENSION STORAGE CO., Heed Building, Philadelphia, Pa., are prepared to furnish batteries in all sizes from portables to station batteries of 5,000 ampere hour capacity.

KENT ELECTRIC MFG. CO., Worcester, Mass., advertise drum armature battery motors which are fully described elsewhere in this issue.

THE GARVIN MACHINE CO., New York, have ready for immediate shipment a large stock of shapers in all sizes and styles.

THEO. AUDEL & CO., 63 Fifth avenue, New York, advertises Hawkins's works on the steam end of electricity.

THE HART & HEGEMAN MFG. CO., Hartford, Conn., advertise porcelain clad Hart flush switches.

MR. M. A. SINGER, 27 Bond street, New York City, is already busy on a number of contracts for booths and decorations for the Electrical Exhibition. He says the results will be unusually fine. Among those he is now working on are the spaces for Henry R. Worthington, Thos. A. Edison, Jr., Zimdars & Hunt, Ideal Elec. Corporation (F. A. La Roche & Co.), Fuel Economizer Co., H. B. Coho & Co., Am. Elec. Novelty Mfg. Co., "Electricity" newspaper and Burrows Electric Horseless Carriage.

NEW YORK NOTES.

E. B. LATHAM & CO. report an increase in demand for the sale of the Tuerk alternating current ceiling fans for foreign countries, having received unusually large orders from France and South America.

F. A. LA ROCHE & CO., 652 Hudson street, New York City, are the successors to the Ideal Electric Corporation, and assume all liabilities. The concern are busy on a large run of work in all lines.

ALFRED DOLGE & SONS. General and deep regret is felt at the receivership appointed for this firm, whose enterprise in the felt industry has built up Dolgeville, in regard to whose development by electric power a long article appeared recently in The Electrical Engineer. The nominal value of the assets is $1,150,000. The debts and liabilities may reach $700,000.

DE VEAU & CO., the manufacturers of telephone and equipment supplies, 27 Rose street, New York, have an order from the Government for telephones for a merchant ship just purchased, to be turned into a man-of-war.

MR. S. BERGMANN, of the Incandescent Arc Light Co., of this city, has sailed for Europe to look after his important interests there, and Mr. Samuel Insull, who is a stockholder in the concern, has taken the vice-presidency of the concern. We understand that the company, which has been remarkably busy, is now getting ready to go into the small dynamo and motor business, with an unusually fine line of apparatus.

NEW ENGLAND NOTES

MR. H. H. BROOKS, of the American Circular Loom Co., of Boston, who has been for the past five months in New Mexico, on account of his health, has now returned to Boston fully restored to his usual good health and spirits. Mr. Brooks is one of the most popular men in the electrical business and his numerous friends will doubtless be glad to see him again among them. Most probably before long he will be taking a little trip through the country in the interests of flexible conduit, and after his pleasant rest in the South for so many months he should be in good condition to take advantage of increasing business.

MERRIMACK CHEMICAL CO., 13 Pearl street, Boston, Mass., report their works at South Wilmington, Mass., very busy. They manufacture acids and chemicals for every purpose in the electrical line, and especially for storage battery uses. Correspondence is solicited from all consumers and dealers using Merrimack Chemical Co.'s products.

SWETT & LEWIS, 11 Bromfield street, Boston, make a specialty of static machinery for Röntgen ray and therapeutic work. They report shipping goods on orders as fast as they can make them.

L. E. KNOTT APPARATUS CO., Ashburton Place, Boston, are sending out to the trade their new catalogue of X-ray apparatus and their general line of philosophical instruments.

WESTERN NOTES

WASHBURN & MOEN, Worcester, Mass., have taken a large contract in St. Louis for all the lead-covered underground cables required in the new system of the Imperial Electric Light, Heat and Power Co. They have many large cable contracts on their books, including one for lead cables for the West Park system, Chicago; and another for high voltage lead cables to be used in conveying the current from Chambly Rapids to Montreal, to be used in that city for light and power.

COLUMBIA INCANDESCENT LAMP CO., St. Louis, report that they have never had a better business than at present. It shows a 50 per cent. increase over the corresponding period of last year.

MR. W. R. GARTON, 414 Ashland Block, Chicago, has just completed arrangements with the United Electric Improvement Co., of Philadelphia, to represent all their products in Chicago, devoting special attention to their high grade incandescent lamps. He will also push their direct and alternating current dynamos and motors, and expects to build up a large trade in the U. E. I. specialties.

SHELBY. The enormous demand for Shelby incandescent lamps, the product of the Shelby Electric Co., of Shelby, O., has caused them to increase their capital stock from $100,000 to $250,000. Plans have been drawn for a large addition to their present plant which will more than double their present capacity. The success of this company is largely due, not only to an excellent product, but to the efforts of Mr. John C. Fish, secretary of the company, whose originality and enterprise are well known to the trade.

PHILADELPHIA NOTES

SCOTT & JANNEY ELECTRIC MFG. CO. have removed their factory from Filbert street to Washington avenue and 22d street, where they have much better facilities for handling the large alternating current machinery which they are now turning out. They also have their own foundry which is directly connected with the main railway line by special tracks running into the yards of the company.

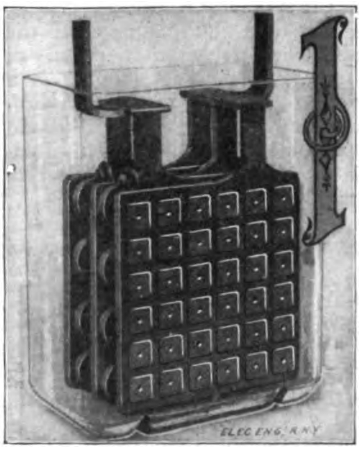
Vol. XXV. APRIL 28, 1898. No. 521.

THE ELECTRIC STORAGE BATTERY CO.—ITS FACTORY AND ITS BATTERY INSTALLATIONS.

BY JOSEPH WETZLER.



IT was in 1881 that the steamship "Labrador" brought to this country the first storage cell, constructed on the Faure plan. Its arrival was very properly hailed as a notable event by electricians and scientists generally. The expectations of all had been raised to a high pitch by the glowing accounts given of the Faure cell by Lord Kelvin, but it is safe to say that if the expectant ones on this side of the water had known how the cells on the "Labrador" had to be guarded, and indeed, fairly nursed, to keep them from falling apart during the voyage, their enthusiasm would have received a severe setback. We can all well afford to smile at this bit of inside history now, and it has been referred to only to bring out into stronger contrast the great developments since made—developments which enable the shipping of battery plates in open crates across the Continent without the slightest danger of their coming to harm.

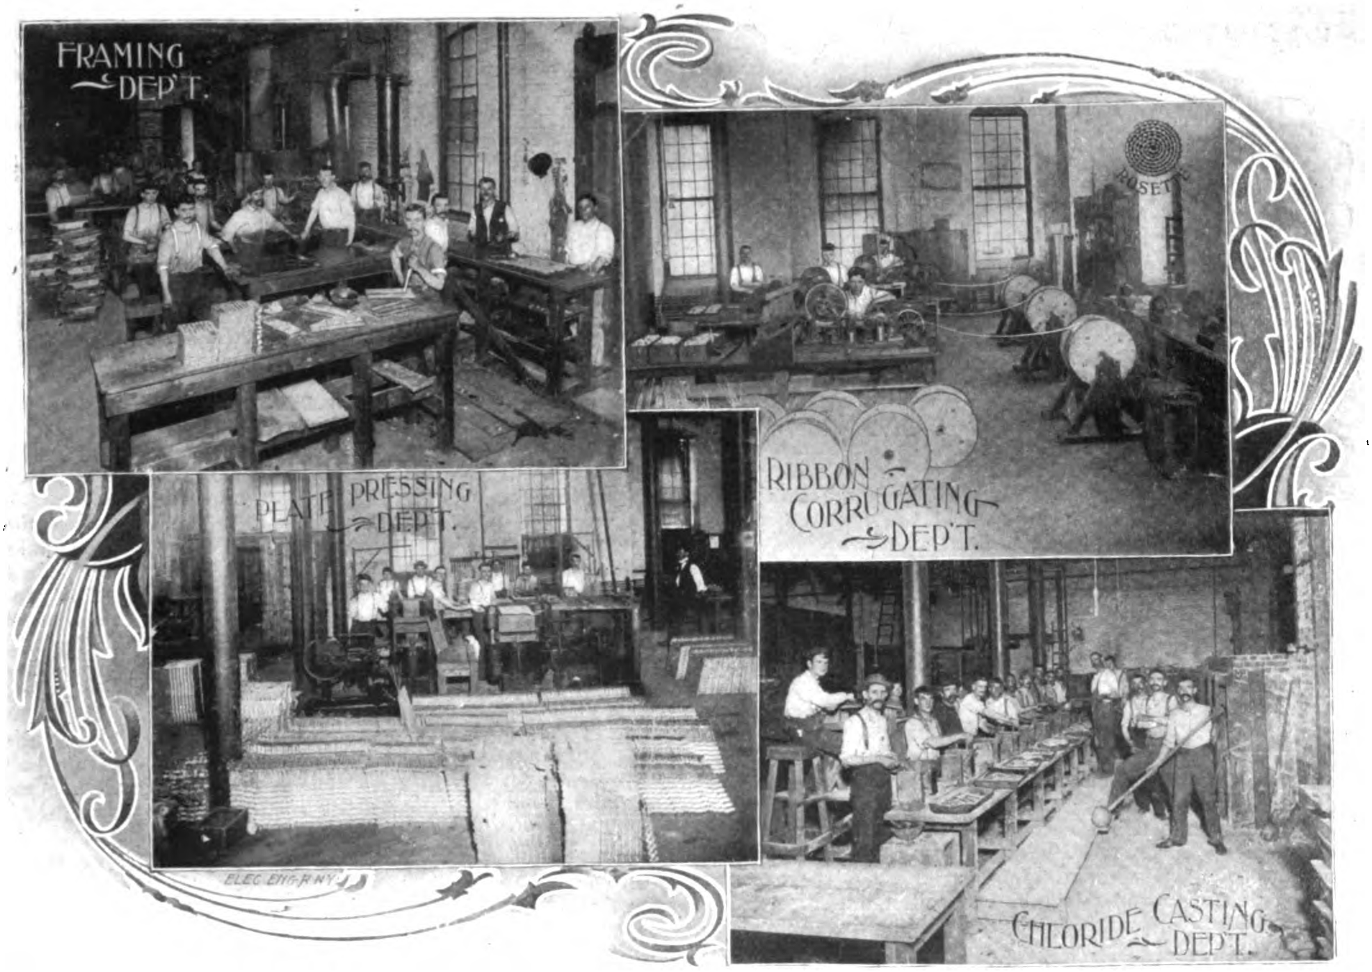
Nor need we here allude to the other technical improvements which have lifted the storage battery out of the electricians' slough of despond and placed it among the "sure-enough" materia electrica—to borrow, or rather paraphrase, a familiar term. Suffice it to say that the storage battery, after many vicissitudes, especially in America, is now acknowledged to be a most valuable, and in many instances, an indispensable, adjunct to economical electrical operation, and that its influence is growing from day to day. This recognition has resulted in an impetus to the storage battery industry such as it has not experienced since its establishment in the United States.

The dawn of this new era of activity in storage battery work seems to be well worth emphasizing by a glance at the present state of the art in America as embodied in the methods of manufacture pursued, and as represented by some typical plants installed by the Electric Storage Battery Co.

At the request of the writer, the company, a few weeks ago, very courteously threw open for inspection every department of its great works in Philadelphia, and the following account is the record of a most interesting and profitable experience.

THE FACTORY.

Before entering into a description of the processes of battery manufacture, it may not be out of place to refer to the structure in which they are carried on. This is the great six-story Worden Power Building, in Philadelphia, situated at the intersection of Allegheny avenue and 17th street, right between the Pennsylvania and the Philadelphia & Reading Railroads, from both of which spurs run directly to the doors of the factory, the cars passing into the central court yard between the two wings of the great building. This location is therefore preëminently adapted for rapid and easy shipment of the finished product—a not unimportant item in any case, but particularly



so in the present instance, where the material necessarily runs to such heavy weights. With this brief glance at the building, we pass in at the door of the office entrance and are soon ushered into the private office of Superintendent Potter, who very kindly offers to take us over the works in person, and whom we will follow as he passes from one department to another and brings us face to face with the scenes depicted in the views accompanying this account.

THE POSITIVE PLATE.

Entering a side door we step at once into the department devoted to the preparation of the positive plates. Broadly described, the positive plate of the "Chloride" accumulator, Manchester form, consists of an active material of peroxide of lead, formed after the Planté method on a rosette or coil of rolled lead tape, corrugated and coiled automatically, and pressed into an antimonious lead frame or grid, which makes a practically non-corrodible, rigid and conductive support.

The first intimation of the positive plate in the factory is the arrival of a car-load of antimonious lead, which is immediately unloaded from the siding, and a sample of which is at once sent to the chemical laboratory for analysis, in order to determine whether or not the lead in question is up to sample.

The lead for daily use is weighed and fed to the melting pots, which are fired by oil and hold about four tons each. The moulds for the positive plate are made of cast iron, with steel buttons corresponding to the holes which are required in the grids. These moulds are hinged, and the feed is orificed to fit a nipple which is connected to a very ingenious lead pump, designed and patented by Mr. Herbert Lloyd, the general manager. Great difficulty was experienced, originally, in securing a valve which would hold the molten lead at the pressure required, but the above scheme of Mr. Lloyd's has worked to perfection for the past eight years.

The air pressure is admitted to the pump by means of a three-way valve, and the grid is cast under a pressure of about one hundred pounds to the square inch. These grids are trimmed and then stored in the Manchester Department, ready to be filled.

The lead ribbon which is, eventually, to become the active material, is received on reels in the form of lead tape, and is fed into the coiling machine, the function of which is to corrugate and cut it into proper lengths and coil it into rosettes of the required size. This machine was designed by Superintendent Potter, to whose skill are due many of the labor-saving devices employed in the works.

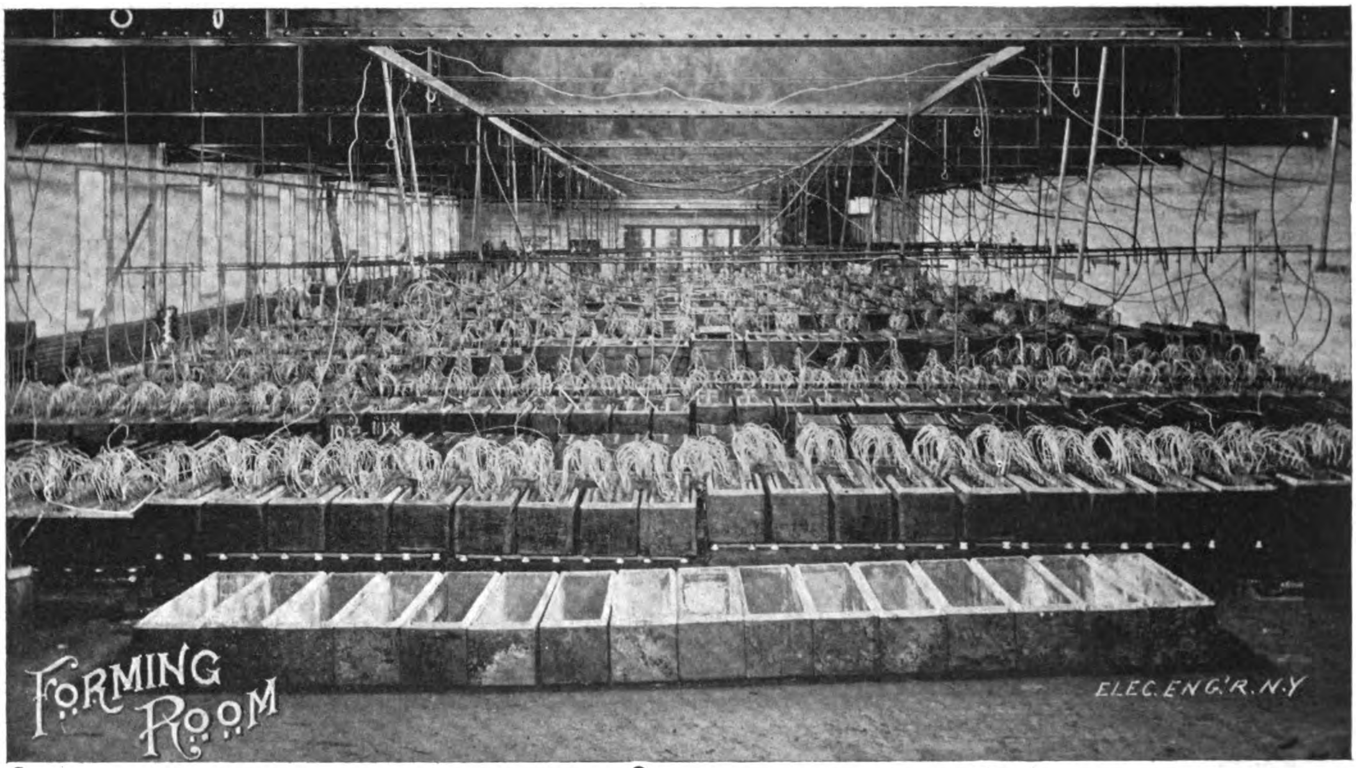
Formerly the rosettes were made by corrugating the ribbon and cutting it by hand, the coiling being done by putting one end of a length of ribbon between two pins on the armature spindle of a small motor, which was started by touching a foot button. In this way a smart boy could make about eight thousand rosettes per day. The above machines do the work of forty or fifty boys.

The rosettes are placed in templates and are driven into the grids by hydraulic pressure. The plates are then ready for forming.

THE FORMING DEPARTMENT.

The forming is carried on in a model building opposite the main building, constructed on principles arrived at after years of experience in rooms of every description. The building is a one-story structure of cemented brick, with a monitor roof, which gives ample light and ventilation. The roof is of wood covered with lead-coated sheet iron, which is painted with acid-proof paint. The floor is made of highly vitrified brick, set in pitch and grouted with the same material.

The forming room, shown on this page, is 60 feet wide and 120 feet long, and the floor has a drop from back to front of one-half inch to the foot, thereby thoroughly draining the floor into a gutter one foot wide, which is also heavily pitched, to five drains connected up to a parallel pipe outside of the building; so that any drains that may need repairing are easily reached from the outside, without disturbing the floor.



The forming tanks are arranged in lines running across the room; a series consisting of twenty of the largest sized tanks across and twenty back; this arrangement allowing of the use of a minimum amount of wire in the forming room. The connections between the tanks are made of specially compounded solder. Mercury was formerly used, but considerable trouble, as well as waste, was experienced owing to the spilling of this material and the amalgamation of the copper and lead connecting the wires.

After the forming process, which occupies several days, the plates are taken out and examined, and a sample of one-half dozen from each four hundred sent to the Commercial Laboratory, for test, and the balance trucked to the store room, being then ready for shipment.

The electrical energy used in the forming room is generated in the engine room, about 200 feet away; the supply being drawn from three 75 kilowatt General Electric generators, belt driven from three 100 h. p. Westinghouse engines; one 50 kilowatt Siemens & Halske; one 75 kilowatt Electro Dynamic Co.; and one 30 kilowatt Eddy generator.

The cables carrying the current are run underground to the

forming room dynamo switchboard and thence to the distributing switchboard through bare copper. The distributing switchboard is so arranged that any machine can be used for any combination of rows of tanks, and is particularly flexible in this respect.

From the distributing switchboard the copper wire is run bare throughout the length of the forming room in a corridor, and the leads pass through the partition in the corridor opposite each row of tanks. This corridor protects the copper and special controlling resistance of tin strips, which are supported on slate and iron brackets, from the effects of the forming room fumes.

THE NEGATIVE PLATE.

The negative plate is composed of pastilles of chloride of lead, keyed together with a frame of antimonious lead, which is forced around them. From this chloride, the name "Chloride Accumulator" is derived.

The chloride is manufactured at the company's Camden factory, and is shipped daily by team, as it is wanted. It arrives at the Philadelphia factory in the shape of white crystalline powder, 100 per cent. pure. The chloride is shoveled into the reverberatory furnaces, which hold about one ton each. When melted, which process requires a great heat, the chloride is ladeled into casting moulds, making square pastilles of four square sub-divisions, divided by two small grooves on each side perpendicular to each other. At the intersection of each in the middle of the pastille is left a hole.

The pastilles, after being trimmed, are conveyed by means of a conveyer to the framing moulds, which are similar in construction to the positive moulds, and are placed by hand in the mould, being held in position by countersunk recesses and small pins. When the mould is filled, the lead pump is again brought into play, and the result is the framed negative in chloride form.

The plate has the superfluous lead scraped from it, and is then sent to the "reducing room." There it is placed between sheets of zinc in an electrolyte of chloride of zinc, thereby eliminating the chlorine from the chloride and reducing the pastille to a very porous, crystalline mass of spongy lead, the crystals of which lie transversely to the plane of the plate, and are beautifully pronounced, being plainly seen by the naked eye.

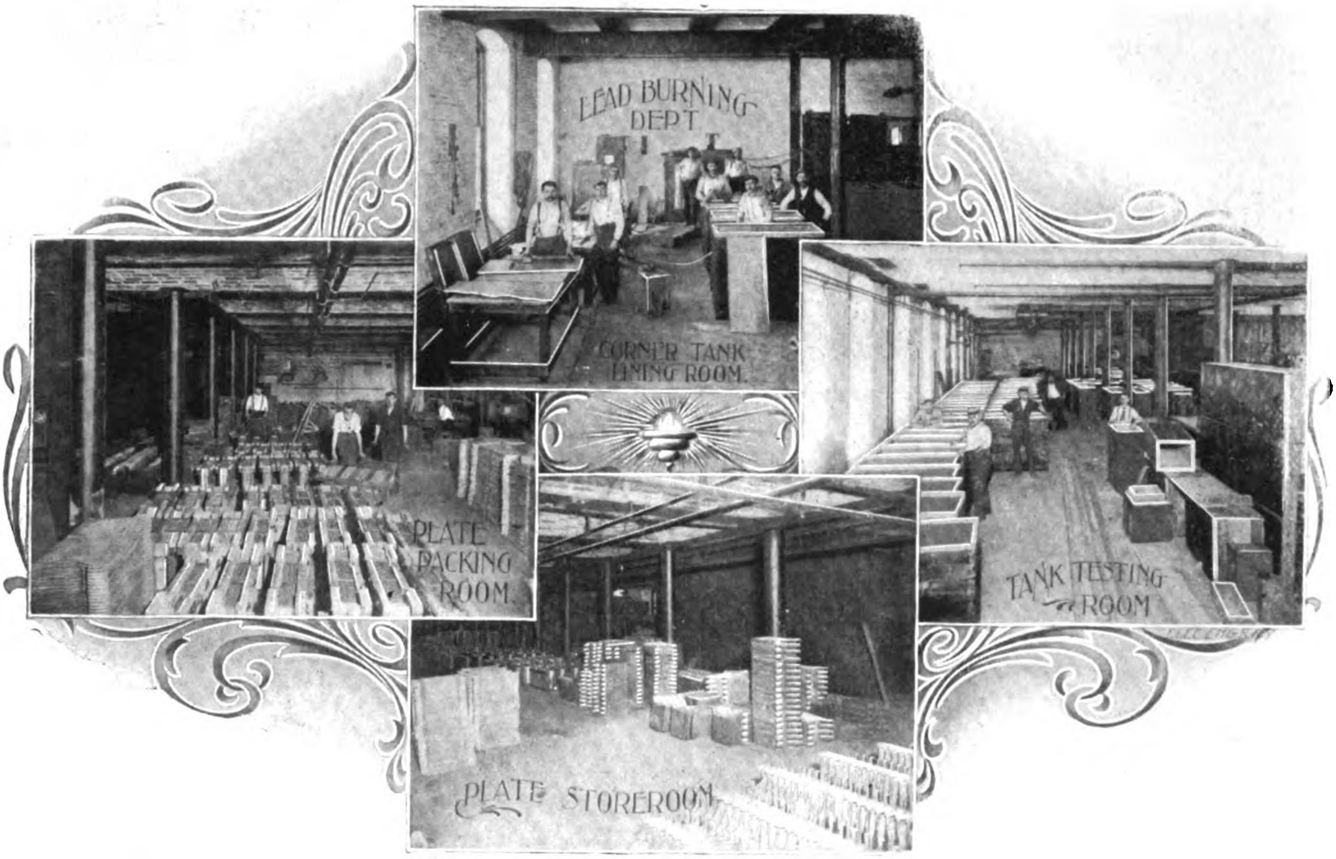
After this process, combined with several washings, the negatives are taken to what is known as the cleaning department, where they are placed in tanks as cathodes to the current, which is applied for several hours; this being merely a test to insure the entire elimination of the chlorine.

From the reducing process is obtained a valuable by-product in the shape of chloride of zinc, of 50 deg. Baumé. This is stored in drums and shipped as sold. From the cleaning department the negatives are trucked to the stock room, whence they are sent to be assembled, or shipped "knocked down," as the case may be.

The smallest plate kept in stock is the size "B," and every size, according to letter, is double in surface and consequently in capacity to that of the preceding letter. The largest plate yet made is the "H," which consists of two "G" plates (16 inches x 16 inches) burned together; this joint makes a solid antimonious lead seam and is as perfect as the rest of the plate; see page 458.

THE ASSEMBLING DEPARTMENT.

The assembling room, situated in the basement of the building, is the scene of the introduction, as it were, of the positive to the negative plates. And it is here that the lug of the strap is burned to the lug of the plate, thereby incorporating them into an element. This process is carried out with the greatest care, making a perfectly homogeneous weld, as no other metal than that of the respective parts is used. For the burning a pure hydrogen flame is employed, which leaves the surface of the melted metal pure and unoxidized. The hydrogen employed for the purpose is made on the premises and stored in a large tank, constituting, in fact, a small gasometer. The proper quantity of air is supplied by a Root blower.



After the burning or welding process is completed, the elements are taken to the packing department and shipped thence to their destinations.

In the sealed cell department is conducted the assembling and putting up of all kinds of portable batteries for phonographs, automatic pianos, sewing machines and many other purposes too numerous to mention. These elements are encased in rubber jars, and are then fitted in well-finished and highly polished hardwood boxes, which are provided with convenient handles.

THE CARPENTER SHOP.

There are several departments, which, while they have no direct bearing upon the manufacture of the plates, are quite essential. Of these the most important is the carpenter shop, in which the tanks are made. In this department the company uses thousands of feet of the best quality of ash lumber, varying in thickness from seven-eighths to two inches. The Electric

Storage Battery Company, in fact, are now the largest consumers of lumber in Philadelphia, a by no means unsignificant fact, considering that Philadelphia is one of the largest manufacturing cities in the country.

This lumber is procured directly from the logging camps in the rough, being carefully selected at the points from which it is shipped. It is received in carload lots and is deposited in the carpenter shop on the second floor, by means of a lumber hoist. The latter consists of a square link chain, with projecting feet at the proper intervals, the lumber being placed upon these and run to the second floor; power being supplied by a pulley belted to the main shaft.

The planks in the rough are cut up into the various lengths, according to the size of the tanks to be made, and are then run over a joiner. Where larger sized tanks are required, the sides are made in two pieces, which are fastened together with dowels and glue; they are then run through a planer and smoothed up. The sides and ends are dovetailed by means of specially designed dovetailing saws. The bottom edges of the sides and ends are grooved and the bottom rabbetted and the sides driven into one end and the rabbetted end of the bottom inserted into the side grooves and driven home, and the other end put on and glued. The tanks are then finished up and are complete without the use of any metallic fastenings, such as nails, screws, etc.

The tanks are lined with lead in the lead-burning department. Sheet lead is cut to the proper size, inserted in the tank and the seams burned with a hydrogen flame.

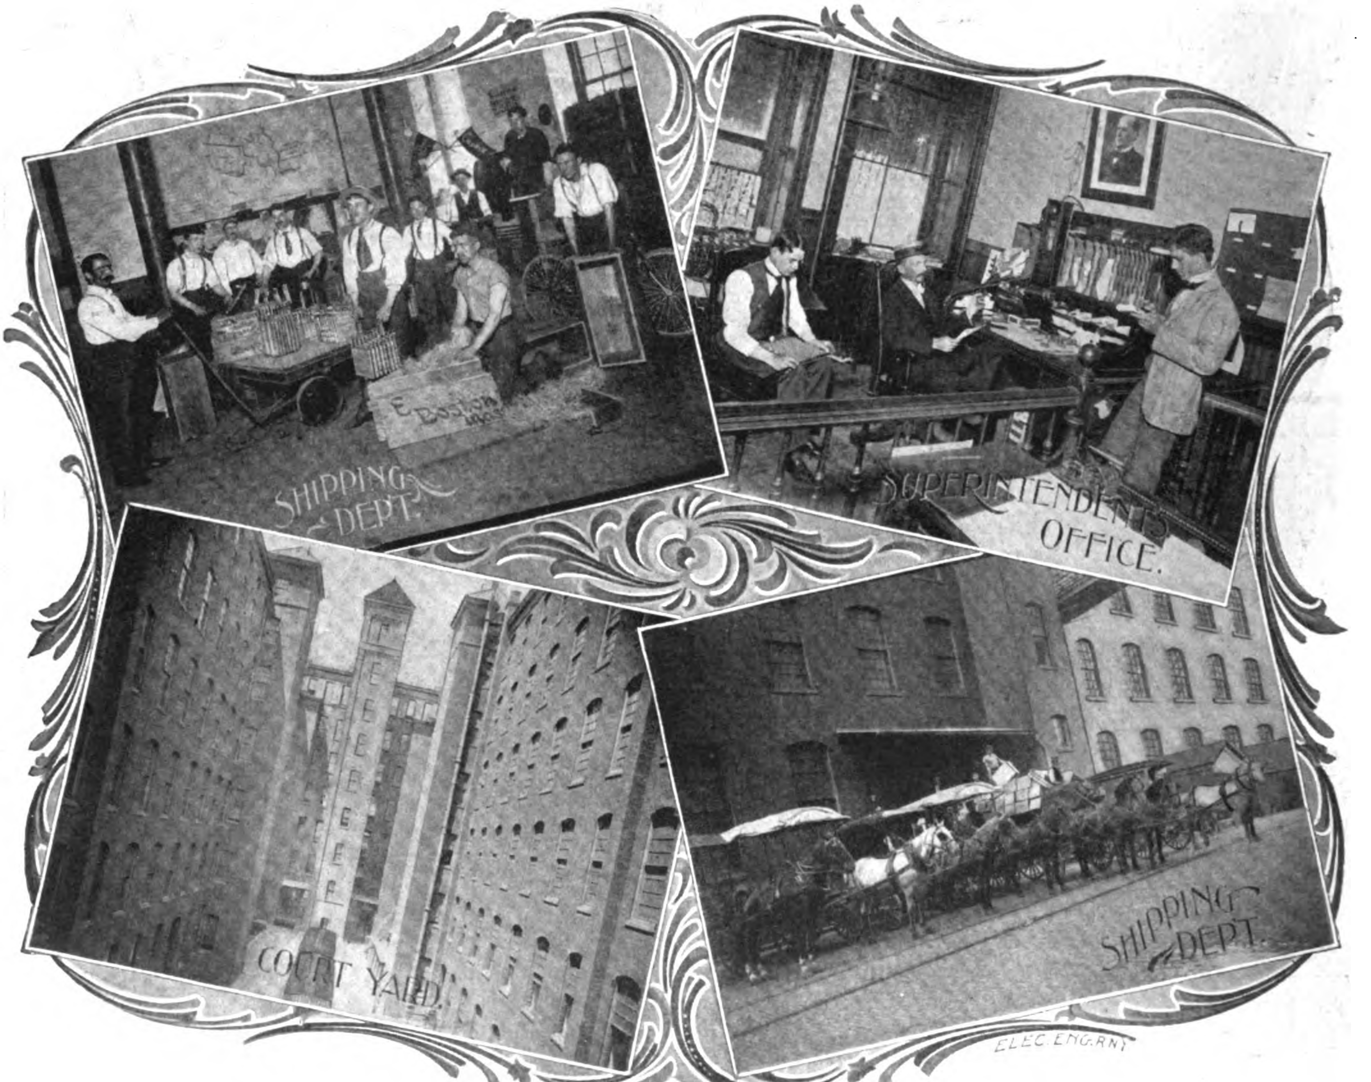
THE MACHINE SHOP.

It goes without saying that a well equipped machine shop is a sine qua non in an establishment of this kind. The machine shop is used for making all necessary repairs, but more especially for the copper work used in the construction of the various installations. All work of this nature is done according to drawings, and it is interesting to note that in a recent installation on the Pacific coast, not one hole in the thousands of pounds of copper shipped had to be even reamed, in order to make the proper fit. Of course, this is due to the efficient draughting corps, as well as to accurate machine work.

In the fitting department are made all the cups which are burned to the bus-bars to receive the copper, both for series and end cell connections; straps for the various sized cells, antimonious lead coverings for brass nuts, used in connecting the elements together; and the various other fittings.

THE LABORATORIES.

Where so much depends upon apparently small things as does the successful working of the storage battery it becomes necessary to investigate very fully and to subject to long and severe tests every detail and every material employed in and around the storage battery. It was to the lack of these tests that many of the early disasters of the storage battery are traceable.



Recognizing, therefore, the importance of testing everything, even to the last drop of water that goes into a storage battery, the company has organized and maintains in constant operation a series of laboratories. Thus, in the chemical laboratory all the lead, acids, water, electrolyte, etc., are analyzed. The company receives samples of electrolyte and water from all sections of the country in which they have batteries, which are analyzed free of charge.

The commercial laboratory is run in connection with the forming room, in order to keep the output up to standard. Sample plates from every batch are tested here, and the department is run night and day by a competent corps of experts.

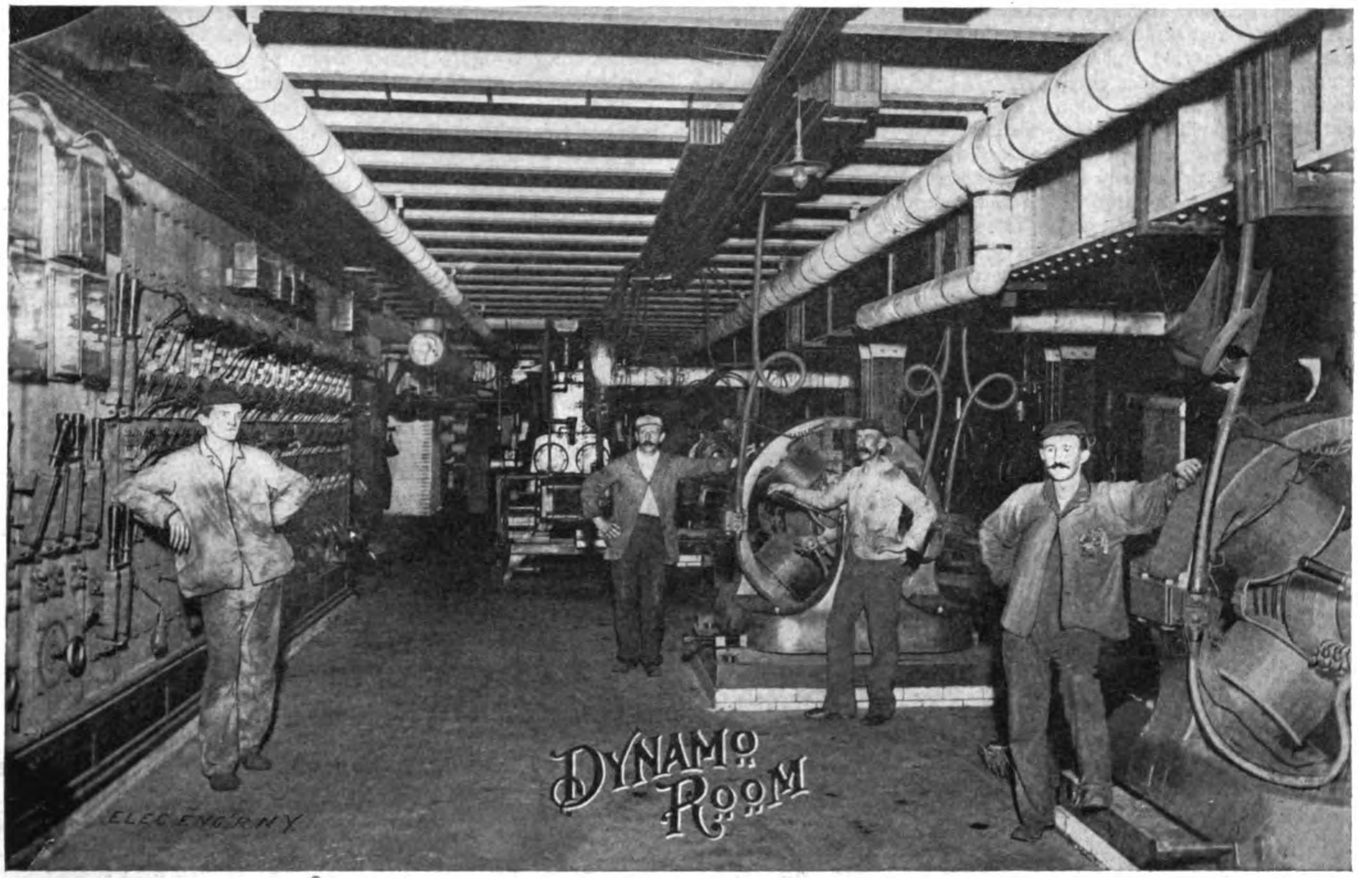
The experimental laboratory is used entirely for the purpose of research, and it is in this department that all the delicate tests are made, in order to determine the value of new types, course of treatment, etc.

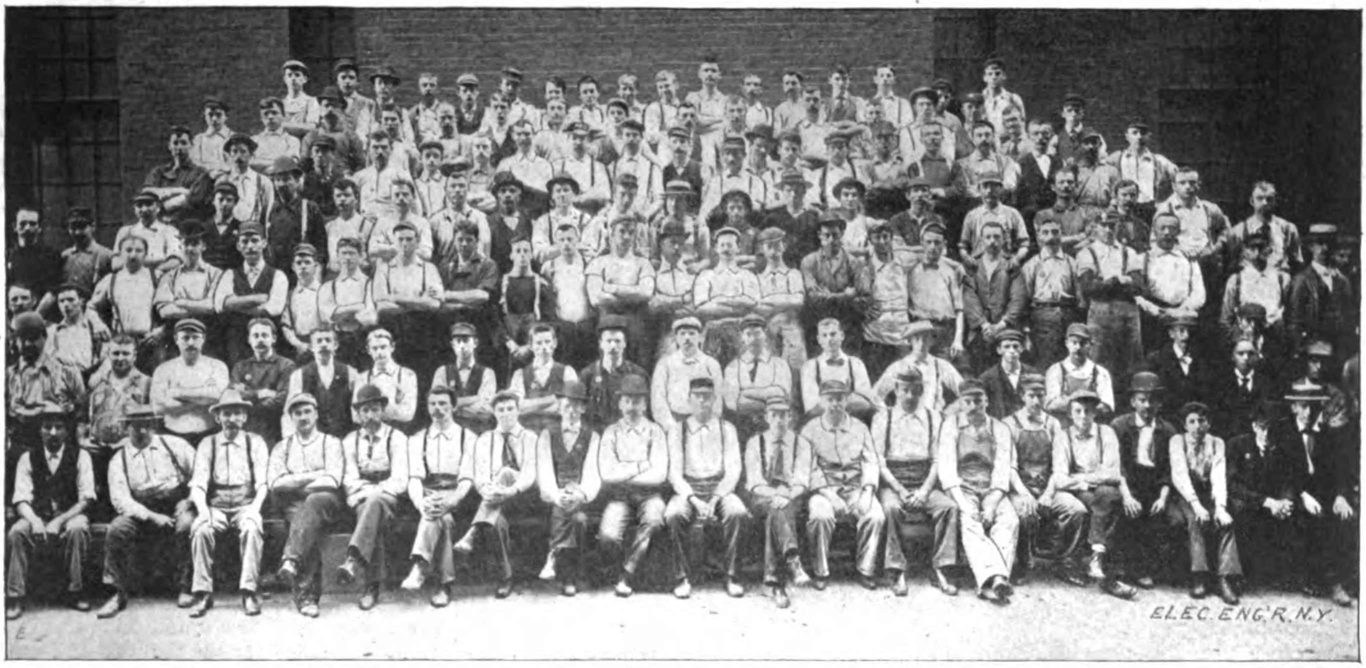
THE SHIPPING DEPARTMENT.

The shipping facilities of the works as noted above, are of the best, spurs running right to the doors from the Philadelphia & Reading Railway, as well as from the Pennsylvania Railroad. The construction of the plates is such as to allow of handling that would have been disastrous to former types. Thus a recent shipment of many tons of plates from Philadelphia to San Francisco arrived intact. The larger sized plates are packed in crates bolted together. These crates, when ready for shipment, weigh about six hundred pounds each, and when unpacked, the crates are returned to the factory to be used again for future shipments.

The mechanical power is derived from two 250 h. p. Westinghouse compound engines, which are clutched to the same shaft in the engine room, and this shaft is belted over a mule pulley to a vertical shaft running to the top of the building. From this shaft 25 horse power is delivered to each floor.

The three hundred, or more, employés have been with the company for the most part for several years and have become particularly well drilled in the class of work which they are called upon to perform.

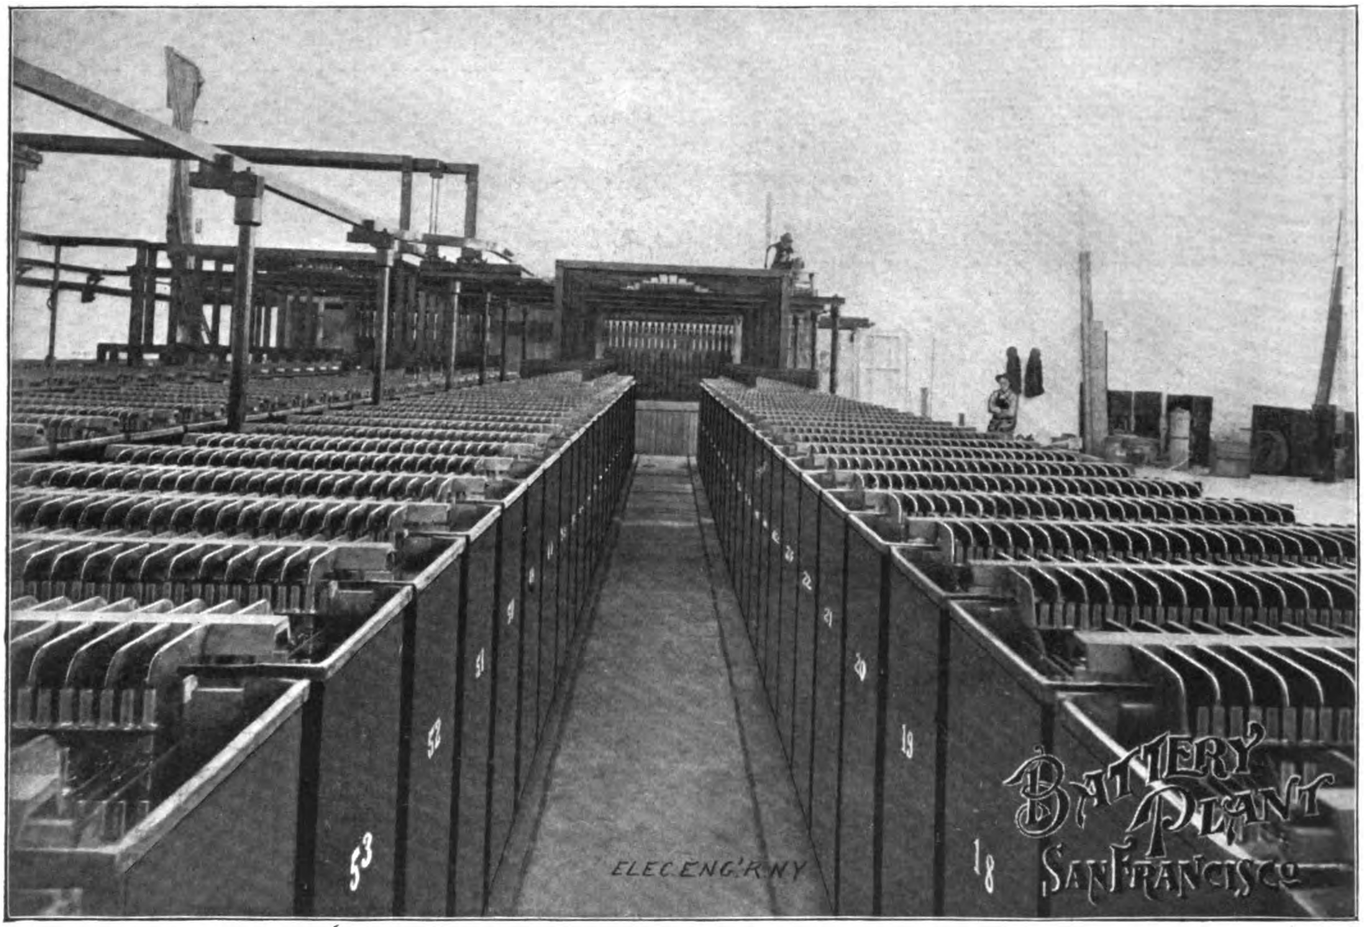




A PART OF THE FACTORY FORCE OF THE ELECTRIC STORAGE BATTERY CO.

THE COMPANY'S INSTALLATIONS.

From the description given above together with the illustrations depicting the various processes carried on in the factory, the reader will have obtained a very fair idea of the company's factory processes, and of its finished products. But equally interesting, if not indeed more so, must be an account of the installations carried out by the company in all parts of the country. A reference, even ever so brief, to all these plants would fill a good sized volume, and hence we will have to content ourselves with describing a number of typical installations, each illustrating one among a multitude of similar plants. These include practically every commercial use of the electric current, showing the application of the storage battery to lighting, railway working, telegraph, telephone, fire and police alarm, to domestic plants, and a variety of other purposes. These classes of work indeed are so numerous that even here we are confined to a selection, in order to keep within the limits of space available; but the installations which we are about to describe will afford a good idea of the scope and nature of the company's work.



A TYPICAL CENTRAL LIGHTING STATION BATTERY PLANT.

As the storage battery has thus far made greatest headway in electric lighting central stations we begin the descriptions of the various plants by an account of the most recent example carried out to completion, namely that at San Francisco, Cal.

The San Francisco Gas and Electric Company, who control practically all the lighting of San Francisco, installed late last year a large battery in connection with their Edison system. The total generating capacity of this portion of their plant is 16,600 amperes, divided up into units as follows: Five direct connected units, 400 kilowatt capacity each; one direct connected unit, 200 kilowatt capacity.

The capacity of this plant was reached in the winter of 1896, and in considering the question of increase, and after carefully weighing the advisability of more generating machinery, or batteries, they decided on the latter, and installed during the summer of 1897 a storage battery plant having a capacity of 1,750 amperes for three hours on each side of the system.

The engraving on this page shows the interior of the building erected especially as a battery house, with the battery in position. The structure is designed to house four such batteries, two on the ground floor and two on the first floor, the foundations and walls being specially constructed for the purpose.

There are one hundred and fifty cells, seventy-five on each side of the three-wire system, the containing tanks being 18 inches long by 46½ inches wide, by 39½ inches deep, inside measurement, all lined with four pound lead.

The connections between the cells are made in the usual manner by welding the plates to lead bus-bars. The regulating switches are erected in a little room partitioned off at one end of the battery room as shown, and these are operated by motors which are controlled from the main switchboard gallery, in the engine room; an electrical indicating device being provided which enables the operator to tell at any time the number of cells in use.

The diagram on page 451 shows the method of connecting and operating this battery in conjunction with the three-wire system.

The load curves shown on page 451 are taken from the San Francisco company's records after the battery was installed. It will be noticed from these that their demands for the winter of 1897 called for the full generating capacity of their station, in addition to which the battery took care of the peak, furnishing 5,000 amperes.

The operation of this battery has been very successful in reducing coal consumption, as it enabled the boilers to be kept on an economical load and prevented the necessity of getting up steam for a run of only an hour or two. The advantages accruing from this can be readily understood when it is remembered that coal costs about $5 per ton on the Pacific coast.

The battery is charged from the main bus through a pair of 50 kilowatt boosters direct connected to a single motor. This machine had been previously installed for the purpose of boosting the current from the main bus for the auxiliary, during the hours of light load, and it is found that in actual operation this machine is fully able to fulfill both functions.

This installation is the first of any magnitude on the Pacific coast and has excited great interest there among electrical engineers and suppliers of electrical power.

The recent development of the extensive water powers in California has made the question of storage of electricity an important one, as in nearly every case these water powers are leased subject to "irrigation rights," which prevents the companies operating these water powers from "damming back" the water when not required. This means that they can only avail themselves of a portion of the total power unless they store the surplus in the form of electrical energy in storage batteries.

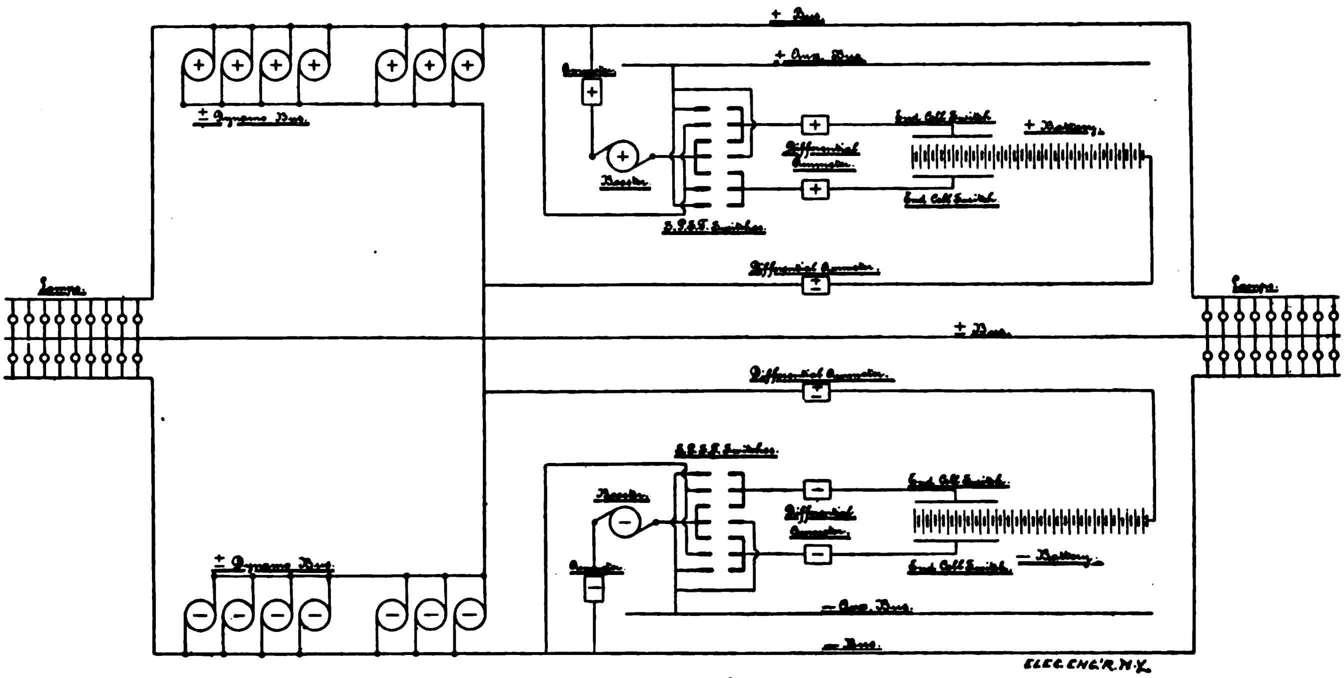


DIAGRAM OF CONNECTIONS, STORAGE BATTERY PLANT, SAN FRANCISCO GAS AND ELECTRIC CO.

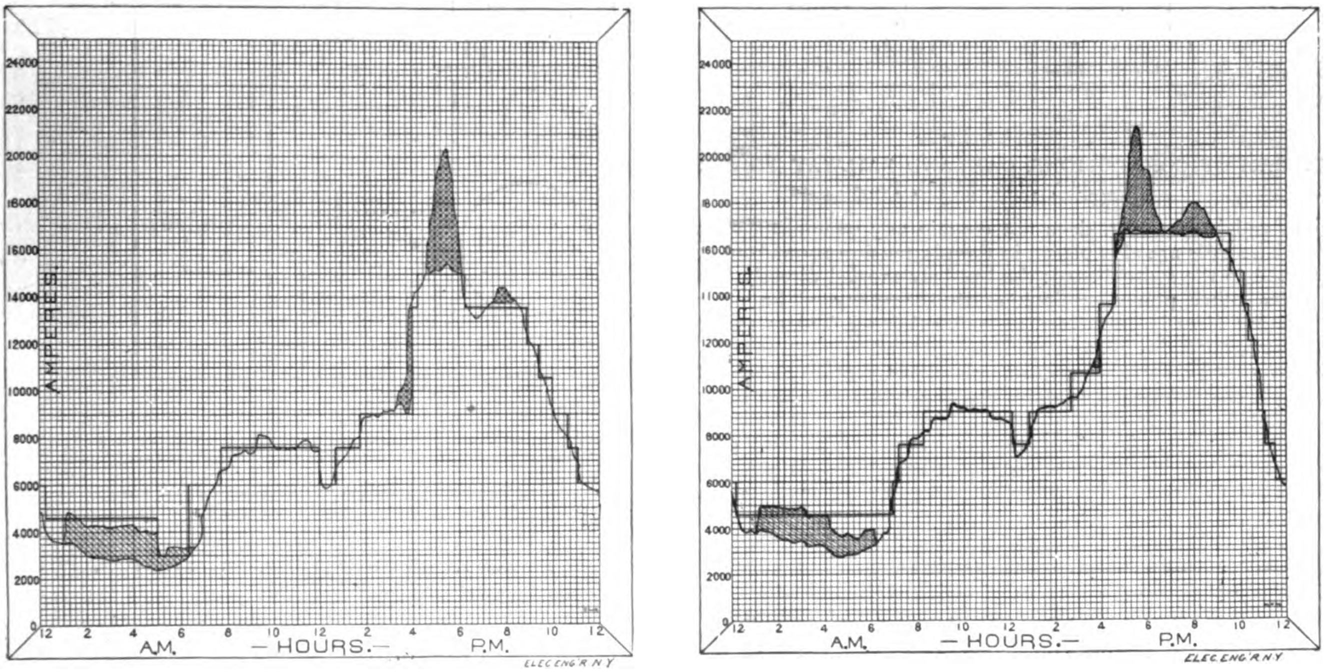
THE STORAGE BATTERY IN RAILWAY WORK.

Until quite recently the work of the storage battery in the United States had been confined principally, to electric lighting, with, of course, numerous minor though not less important applications. But after ten years of electric railroad work it suddenly dawned on street railway managers that the conditions under which they were operating were such as to render the use of a storage battery of the very greatest economical importance. Although, as just stated, this recognition has come somewhat late it is being acted upon with all the more alacrity. Already a number of railways have been equipped in this manner, and we propose to describe briefly the latest installation of this kind.

Upon the organization of the Consolidated Traction Company from the several lines in Pittsburg which form that corporation, the new company faced the problem of the proper rearrangement of the power generation for the most economical operation of the road from its seven power houses, three of which were electric and four cable, and all of which had been built for the needs of the several independent lines. One of the results of the solution of this problem was the adoption of storage batteries as station auxiliaries.



LOAD DIAGRAM OF SAN FRANCISCO GAS AND ELECTRIC CO., AFTER INSTALLATION OF STORAGE BATTERIES.
The Single Cross Hatched Portion Indicates Battery Charge. The Double Cross Hatched Portion at the Peaks Indicates Battery Discharge.

During June, 1897, the Electric Storage Battery Company installed for the Consolidated Traction Co. two plants, located at the Oakland Station, on the corner of Fifth avenue and Atwood street, and at Thirty-fourth street and Penn avenue. The

former of these plants consists of 260 cells, and the latter of 248 cells, each capable of discharging at the rate of 500 amperes in regulating the rapid fluctuations of load, the difference in the number of cells being due to the difference in voltage at the two points.

The engraving on page 453 shows the plant installed at Oakland Station. The latter is an old cable station, the batteries occupying the space formerly devoted to the tension room. The old cable engines are still in use, two in number, each driving one end of a shaft, the main driving drum on this shaft having been replaced by an 800 kilowatt generator, which is thus directly driven.

The battery is connected in parallel across the bus-bars, as would be the case with another generator, and is controlled directly on the switchboard by a separate generator panel, with circuit breaker, ammeter, voltmeter, and quick break switch. The ammeter is not of the ordinary type, but differential reading, with zero point in the centre of the dial; it gives the flow of current in each direction, and during most of the day the indicator oscillates from one side of the scale to the other with the variation of the external circuit. See diagram, below.

The battery at Thirty-fourth street also occupies an old cable

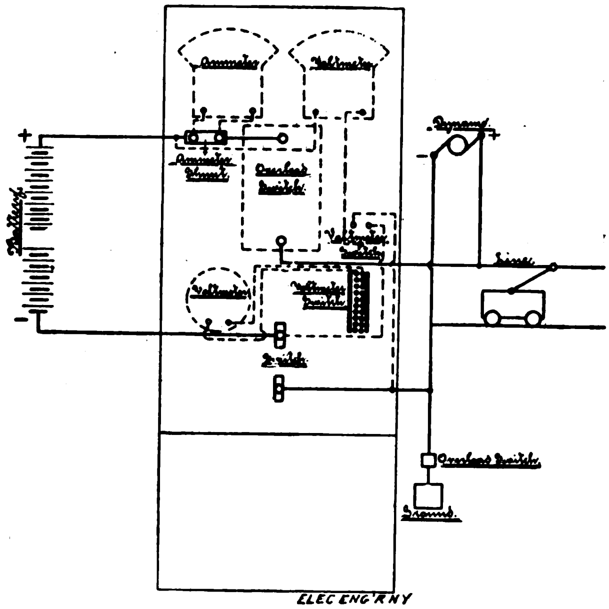


DIAGRAM OF CONNECTIONS, OAKLAND RAILWAY POWER HOUSE, PITTSBURG, PA.

station, which, however, does not contain any generating apparatus. The cells are also placed in the old tension room, and are connected to the switchboard; the bus-bars are fed directly from the three other power stations of the company. The power stations are directly connected to each other by feeders as well as by the parallel circuit, a condition which while not impossible were no storage batteries in use, would yet require some care to prevent the reversal of some of the generators at a low potential station and their operation as motors by the generators at the other stations. The batteries act as reservoirs and regulators somewhat in the same way as stand pipes in pumping stations act to keep the pressure on the pumping engines constant.

The flexibility in the manipulation of power stations secured by the use of storage batteries is remarkable. The engineers can adjust the load between the different power stations as desired by changing the voltage. Thus, if any one station were carrying less load in proportion to its capacity than the other stations, the engineers at that station would cut out some field resistance, raising the voltage at that station and throwing it on more of the mutual load by relieving the other stations. This renders possible the shutting down of part of the equipment of a station for repairs during a heavy demand for current by making the other stations carry part of the load in the station in which the repairs are being made.

It has been found that the capacities of the stations have been greatly increased in excess of the added output of the batteries, so that while in the consolidation of the different systems three cable plants were abandoned, no additional generating apparatus has been installed, although the number of cars operated has been largely increased. This is attributed by the managers to the elimination in the loads of the momentary peaks which really set a limit to the output of the generators. Thus, in the Consolidated Traction Company's system, in Pittsburg, a station containing an 800 kilowatt generator in connection with a 500 ampere hour battery has given an average output of 2,000

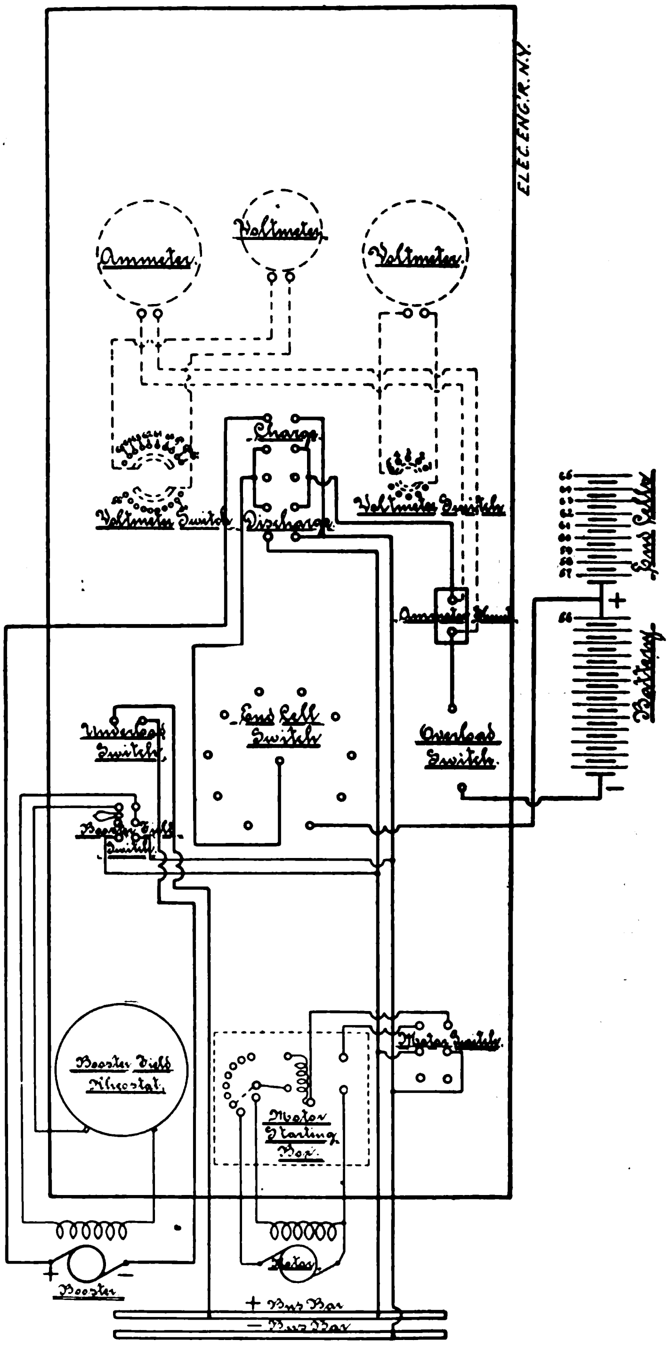

DIAGRAM OF SWITCHBOARD CONNECTIONS, STORAGE BATTERY PLANT IN READING TERMINAL STATION, PHILADELPHIA.

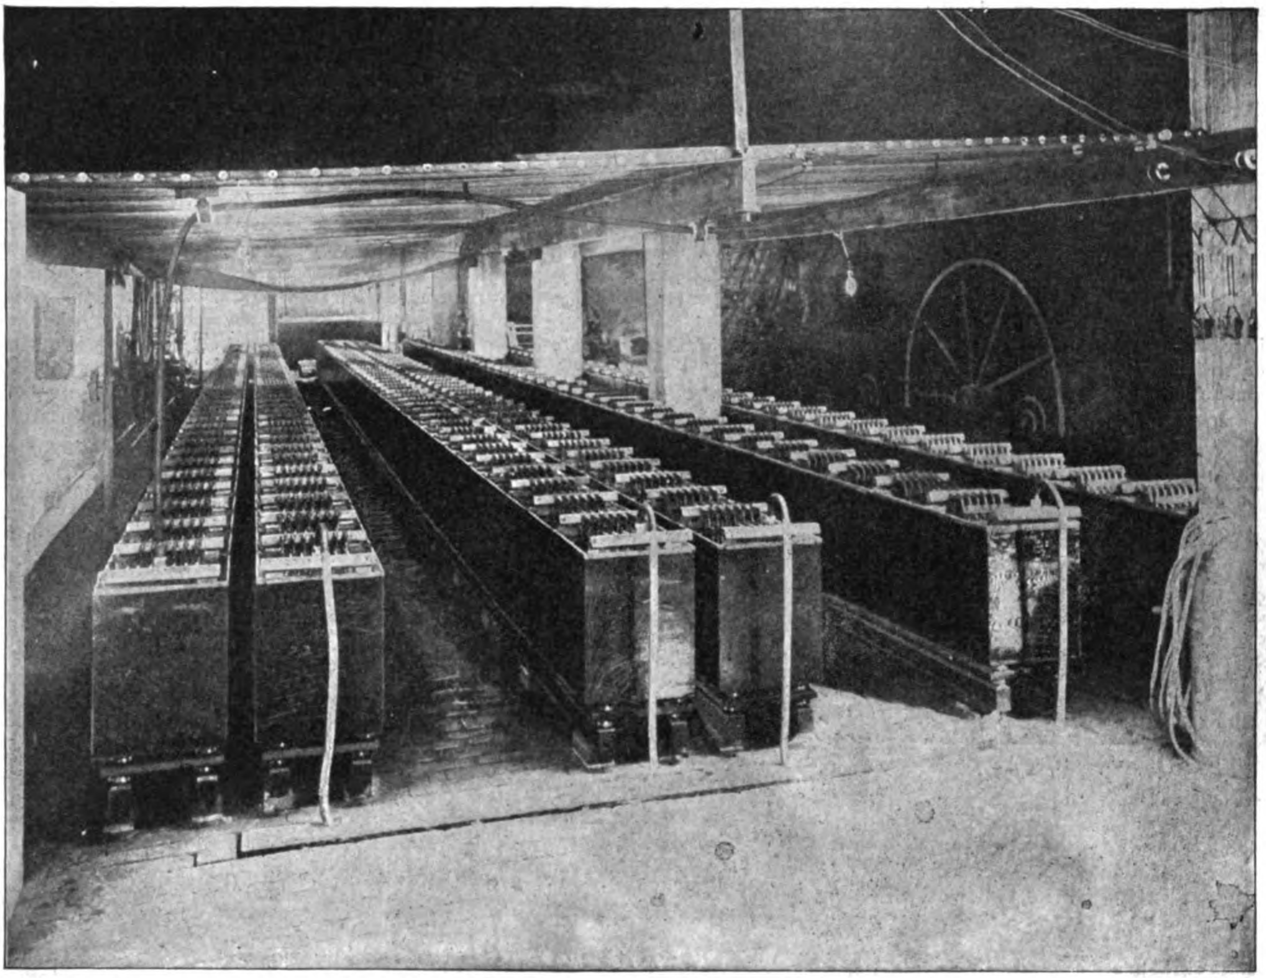
amperes continuously at about 525 volts for twenty-four hours without destructive effect.

A TYPICAL RAILROAD STATION BATTERY PLANT.

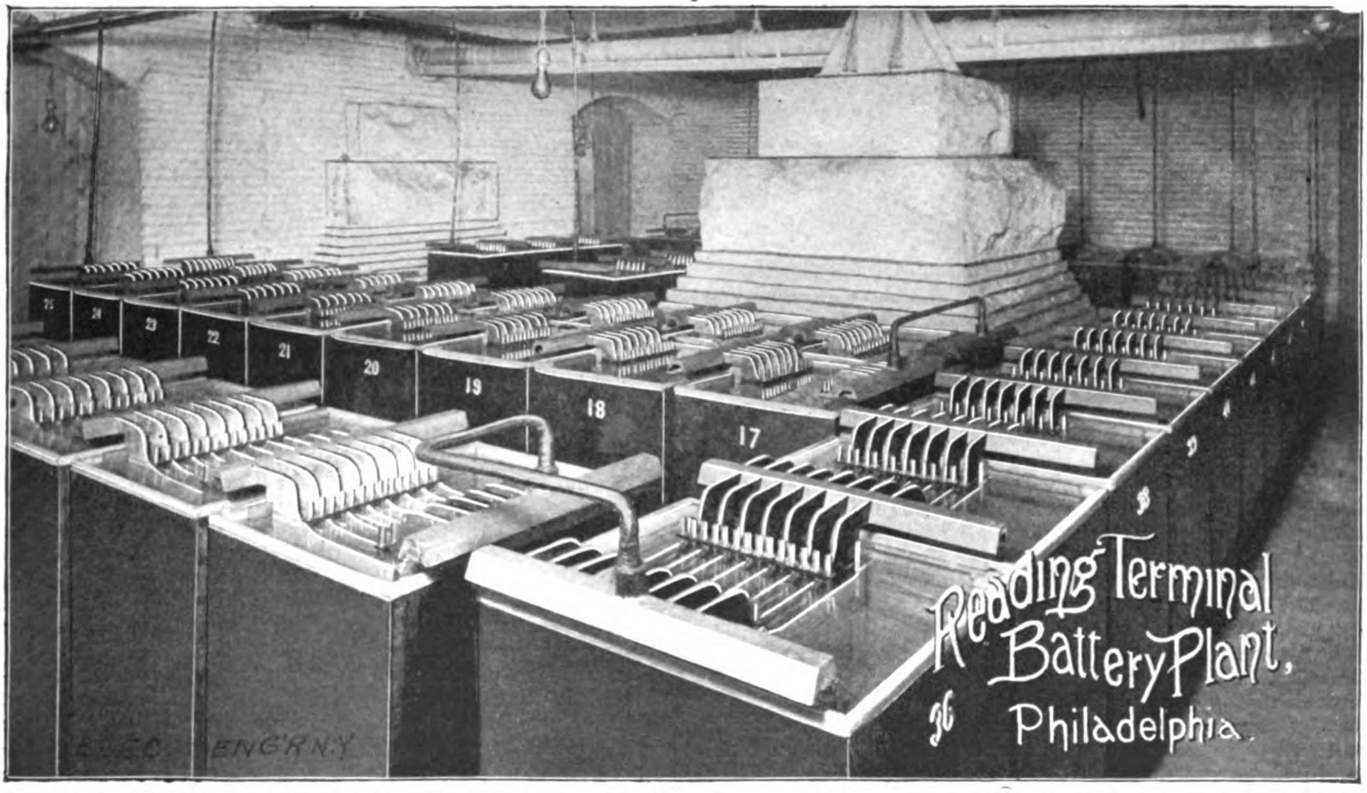
A notable plant recently installed in Philadelphia by the Electric Storage Battery Company, is that at the great Reading Terminal, the home station of the Philadelphia & Reading Railway Company, and shown on the page opposite.

The battery is an adjunct to the lighting plant which not only supplies the waiting rooms, ticket offices and train shed, but also the ten story office building and large market houses that are included in the one structure. This lighting plant consists of

two alternating units and three direct current units besides a number of arc light machines and the battery. The last contains



STORAGE BATTERY PLANT, OAKLAND POWER HOUSE, CONSOLIDATED TRACTION CO., PITTSBURG, PA.



65 cells of Chloride accumulator 15-G type, of 980 ampere hours capacity, capable of discharging at a maximum of 560 amperes.

The plates are contained in lead-lined wooden tanks large enough to allow of an increase in the capacity of the battery to 1,400 ampere hours by the simple addition of a proportionate number of plates which can be inserted and burned in at any

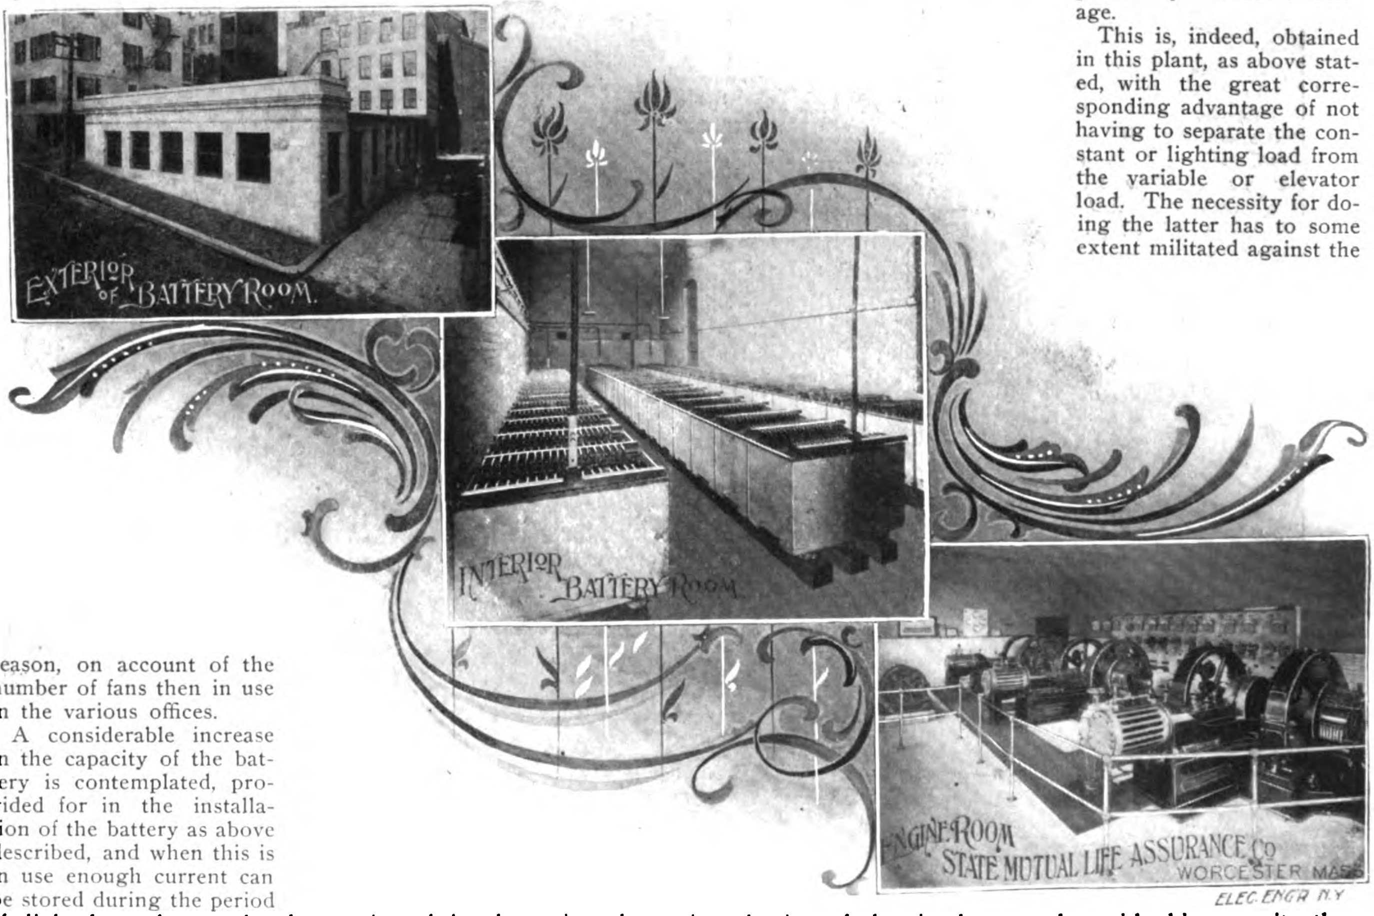
time. In this connection it may be mentioned that in accordance with the best modern practice the plates in this plant are burned into place to heavy lead bars between each tank, and the cable leads are burned into lead cups in the bars, thus entirely eliminating all bolts or clamps and making lead the only exposed metal throughout.

The switchboard is the standard panel of the Electric Storage Battery Company when a motor driven booster is used and the connections are shown in the diagram on page 452.

The function of the battery in this plant is to aid in carrying the peak of the load which accrues during the evening of each day and to carry alone the entire load for several hours each night. Besides this, a by no means unimportant service fulfilled by the accumulator is to take care of any sudden demand that may come upon the circuit. For this purpose it is kept constantly across the bars and has more than once prevented an interruption of the service.

As a result of the ability of this battery to take care of the peak of the load the alternating machines are shut down entirely during the summer, a great convenience, if for no other reason, on account of the number of fans then in use in the various offices.

A considerable increase in the capacity of the battery is contemplated, provided for in the installation of the battery as above described, and when this is in use enough current can be stored during the period of slight demand to render the running of the alternating plant entirely unnecessary, making through the saving in labor, etc., a very substantial return on the battery investment.



AN OFFICE BUILDING PLANT.

An exceedingly novel and interesting application of the storage battery as an adjunct to an electric plant is exemplified in the installation of the State Mutual Life Assurance Company's building. The plant supplies electric light and power for offices and elevators in the splendid home of the company at Worcester. Mass. It is housed in a well designed separate one-story building permissible by the low price of real estate, and this allowed a more than usually generous treatment as to the space allotted to the apparatus.

The generating plant consists of three direct coupled units. There is also in connection with the battery a specially wound motor-driven 16 kilowatt booster generator built for the Battery Company by the General Electric Company. The boiler plant which furnishes steam for heating the building in addition to that required by the engines, consists of Babcock & Wilcox water tube boilers. Three views of the plant are shown on this page.

Besides its usual duties as a reservoir for carrying the night load and aiding with the peak, the storage battery has here its capabilities as a regulator brought to practical perfection. This is rendered specially necessary because of the electric elevators in the building. There are four of these, of the Sprague screw type. By the use of the battery it is possible to supply current for these from the same generator that supplies the lamps, without in any way affecting the steadiness of pressure on the latter. This result is obtained by combining with the battery the special booster above referred to. This booster is so connected as to aid the inherent tendency in the battery to respond to sudden demands on the circuit to which it is connected, and to prevent these fluctuations from coming upon the generators. This it does to perfection in this case and there is not at any time a greater variation than one per cent. on the lighting bus even with the greatest elevator load. The battery ceases to charge, and discharges in aid of the generators, whenever an elevator starts and the adjustment can be made so that the variation in current on the generators will not exceed a given amount. Of course with compound generators this means a practically constant voltage.

This is, indeed, obtained in this plant, as above stated, with the great corresponding advantage of not having to separate the constant or lighting load from the variable or elevator load. The necessity for doing the latter has to some extent militated against the introduction of electric elevators, but with this necessity thus effectually removed the very great advantage of not having to add any hydraulic machinery to an office building electric plant will do much to strengthen the position of the electric type.

A RESIDENCE LIGHTING PLANT.

The desire to have the benefits of the electric light extended to country residences as well as to their town houses has led many to install isolated plants on their country places. Among these is Mr. Frank Thomson, president of the Pennsylvania Railroad. At his widely known country seat, Corker Hill, this gentleman has, in conjunction therewith, what may be called a model isolated lighting plant. From this the house, stable, grounds, etc., are lighted by electricity absolutely independently of any outside source.

The building, which is shown in the group on page 455, contains the lighting plant; it is of rough gray stone about 17 feet wide by 60 in length, having a peaked roof of blue slate, the whole making an exceedingly picturesque feature of the landscape. The house is thoroughly fireproof and is well and substantially built though without any undue expense. It is provided with a cement concrete floor and is divided into three in-

terior rooms by partitions of plastered wire lathing. These rooms, views of which are given, are engine room and battery room; the switchboard is also shown.

The engine is a 26 horse power special electric light, Otto gasoline engine. The gasoline for the engine is pumped directly from the barrels into a tank sunk in the ground outside the building, thus removing all danger of explosion.

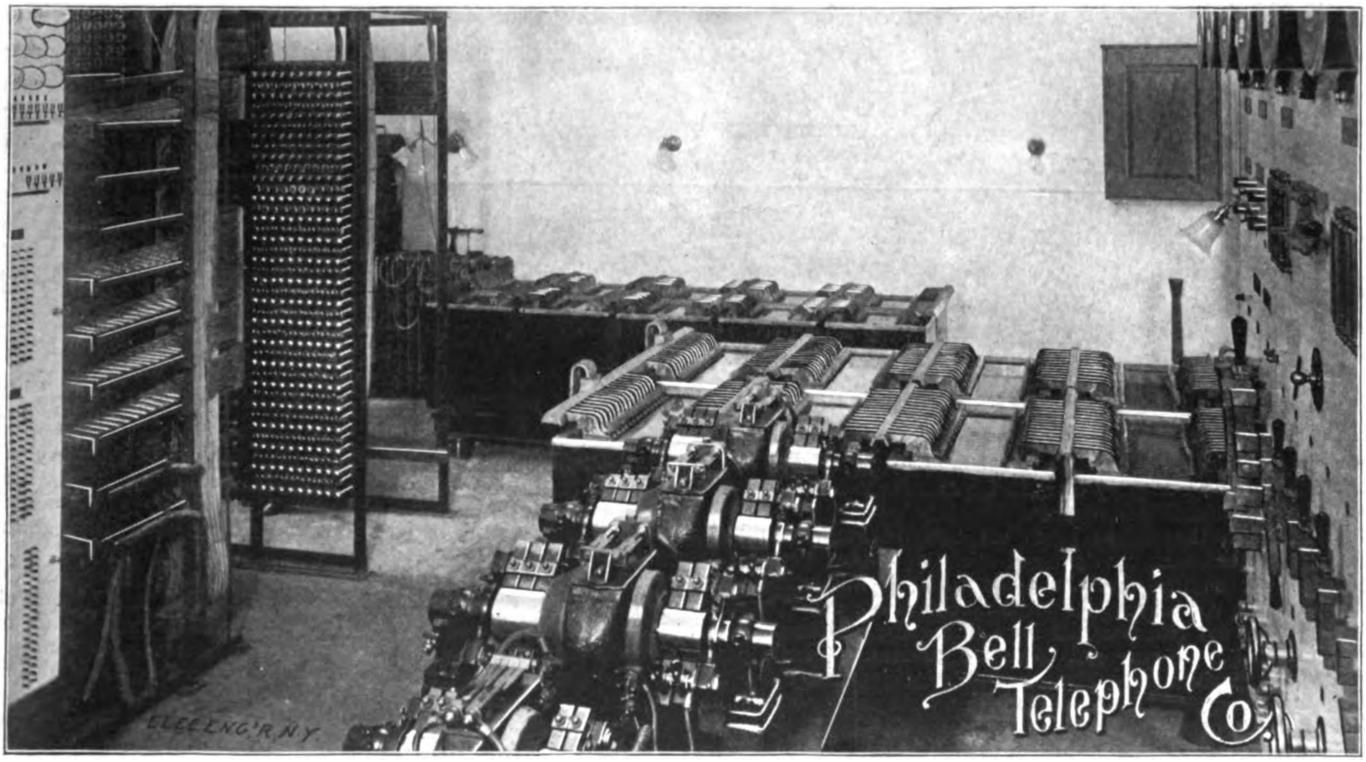
The dynamo is a 20 kilowatt Electro Dynamic Company's, 150-volt shunt wound generator, belted to the engine and provided with a heavy fly wheel pulley thus aiding the engine in maintaining a constant speed. The switchboard is of white Italian marble set in a polished oak frame in the partition between the engine room and the engineer's private room. From this board are controlled the following operations: Lighting direct from dynamo with or without battery in parallel. Charging battery, providing light at same time, or not, as desired. Discharging battery on lights alone.

The battery consists of 62 cells of Chloride accumulator 11-G type contained in lead-lined ash tanks arranged in two tiers on wooden stands so disposed around the battery room as to permit easy access to any cell.

The principal functions of the battery in this plant are to insure absolute steadiness in the light furnished by compensating for unavoidable variations in speed of the engine and dynamo, and to render the light available at any hour of the twenty-four without requiring the engine to be run except at the most convenient times.

The current from the plant is carried a distance of three hun-

VIEWS OF STORAGE BATTERY LIGHTING PLANT AT MR. FRANK THOMSON'S COUNTRY SEAT, CORKER HILL, PENN.



dred yards on a line that is carried partly underground and partly on poles to a distributing board in the basement of the house. From this board are controlled the various circuits of the quite extensive system such as that for the stable, billiard room, etc.

The battery is usually charged at night by the night watchman. As the operation of the apparatus is largely automatic this does not interfere in any way with his other duties, and at the same time the expense of a special attendant is rendered unnecessary.

THE STORAGE BATTERY IN TELEPHONE EXCHANGES.

Modern telephone practice has made a great advance by centralizing the batteries needed by the subscribers in talking. This practice not only results in direct saving of cost of battery power, but also materially improves the efficiency of the service by having the batteries together and in a place where they are under constant supervision of experienced men. The storage battery also furnishes all current for automatic signaling.

The most up-to-date telephone installation of this kind is that recently put in operation in the splendid new exchange of the Bell Telephone Company of Philadelphia, situated at the corner of Eleventh and Filbert streets.

Situated in the engine room are two machines, forming a duplicate plant, each consisting of one New York Safety Steam-Power Co. engine, direct coupled to a 30 kilowatt General Electric 110 volt dynamo. These machines are run alternately every other day and are used for lighting the building and furnishing power at 110 volts to motor generators in the power room on the sixth floor, illustrated on page 455, used for charging the storage batteries and furnishing ringing power to the telephone switchboard.

The motor generators furnished by the Crocker-Wheeler Company, have their primary ends connected to the 110 volt direct current circuit fed from the generators in the basement. These motor generators comprise two 1,500 watt machines for charging a 20 volt battery; one 1,500 watt machine charging an 8 volt battery; one 500 watt machine charging a 4 volt battery; and two ¼ h. p. 75 volt alternating current motor generators for ringing.

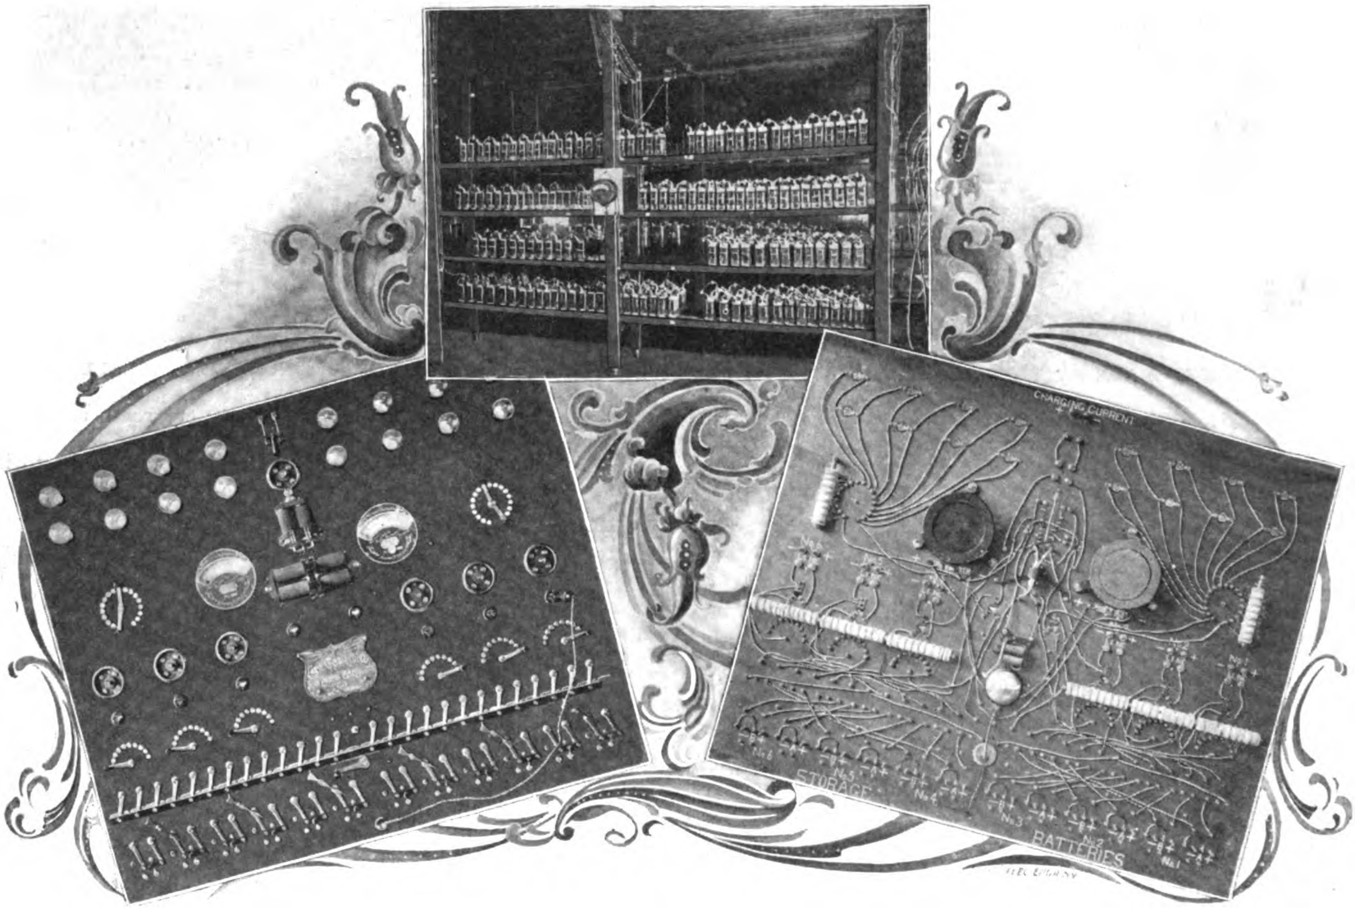
Only one machine is furnished for the 8 volt and the 4 volt batteries which are in duplicate. To avoid a possible breakdown, a Carpenter enameled rheostat is furnished so that the batteries of lower voltage can be charged from batteries or motor generators of higher voltage. All machines are protected with automatic safety cut-outs.

The 20 volt battery consists of ten No. 13 G type Chloride accumulators, which furnish all the current needed by the subscribers for talking and for calling up the office.

The 8 volt battery, in duplicate, each consists of four No. 31 cells. This battery furnishes current for the "disconnect" signals on the operators' cords and for the relays which cut out the subscriber's lamp signal when the operator answers his call by plugging into the jack corresponding to the lamp signal.

The disconnect lamps are so wired that they burn only when the subscribers connected by the cord need attention from the operator. They do not light while the subscribers are talking.

Half the drop in potential of the 8 volt battery is in the 4 volt lamp, and the other half in the cut-out relay. This battery is in duplicate, so that one can be charged while the other is being discharged. This avoids danger of burning out the lamps, as the voltage of the battery is raised from 8 to 10 volts during charging.



MUNICIPAL FIRE ALARM AND POLICE TELEGRAPH STORAGE BATTERY PLANT, WILMINGTON, DEL.

The 4 volt battery consists of six 13 F cells, in duplicate. One of these sets consists of four cells, two in series, two in multiple; the other of two cells. The two extra cells are needed on one of the batteries to supply current for the operators' transmitters. This battery is arranged to furnish a current of 4 volts or 2 volts, as desired. The 4 volt battery also furnishes all current for lighting the lamp signals which light when a subscriber takes his telephone off the hook. This lamp is put out when the operator answers the call, as was described under the 8 volt battery. This battery is made in duplicate, one being charged while the other is discharged, to avoid burning out the lamp from the higher voltage during charge.

The power switchboard and mounting fuse board are con-

structed of white marble, mounted on an iron frame, and equipped with switches, measuring instruments, fuses, etc., for the necessary circuits.

The function of the battery is as follows: The subscriber, by taking his telephone off the hook, operates a relay at the central office, which operates a 4 volt lamp in front of the operator at the switchboard; this lamp is extinguished as soon as the operator plugs into the jack. The cord with which the operator connects together the jack of the subscriber calling with that of the

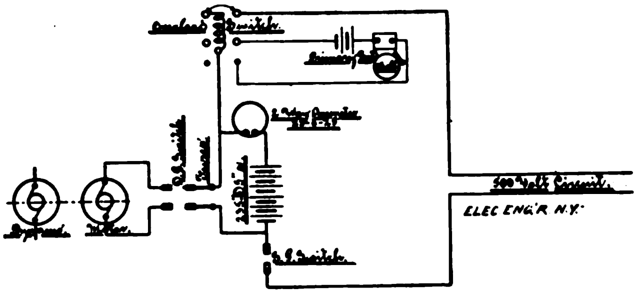


DIAGRAM OF CONNECTIONS OF STORAGE BATTERY, POSTAL TELEGRAPH CABLE CO., ATLANTA, GA.

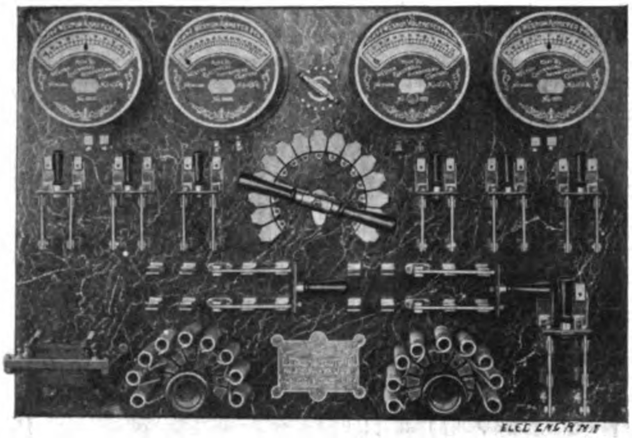
subscriber desired is wired to the 20 volt battery, which furnishes all the current used by the subscriber in talking. The automatic 4-volt lamp "disconnect" signals on the operators' cords are operated in the manner already described.

This storage battery installation has turned out even beyond the expectations, and when one considers that it replaces thousands of cells scattered over a wide area among subscribers, its convenience as well as its economy and reliability will be appreciated by others besides telephonists. It is, indeed, only a question of time when all telephone exchanges will have their electrical energy concentrated at the central office under the constant supervision of the technical staff.

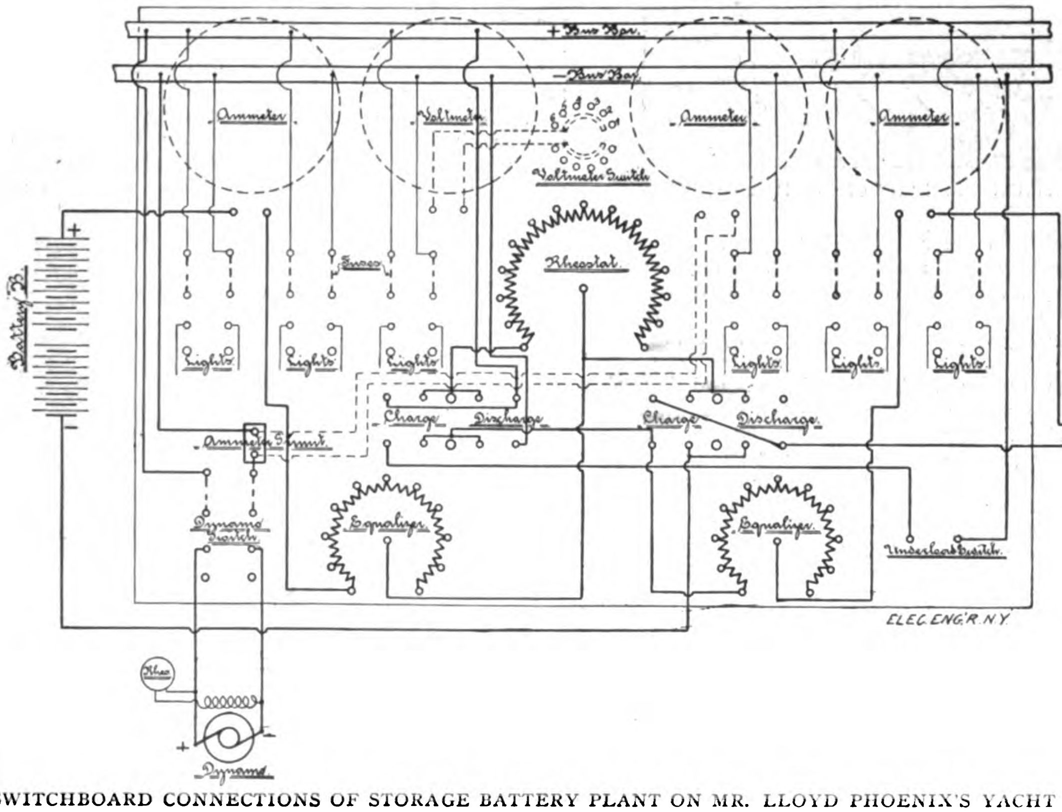
THE STORAGE BATTERY IN A TELEGRAPH OFFICE.

An interesting application of storage batteries to telephone and telegraph work is their use as a regulator to the source of current, when for any reason the latter is of variable potential.

As an example, the installation at the Postal Telegraph-Cable Company's station at Augusta, Ga., may be cited. In this case the source of current is a trolley circuit. From this circuit current is taken through motor generators for the lines. In order to avoid the bad effects of the variable potential on the railway circuit a battery of Chloride accumulators is connected across the terminals of the motors. This battery alternately charges and discharges with the variable potential on the railway circuit and prevents the fluctuations from exceeding an allowable limit. Owing to the low internal resistance of the storage battery it is impossible that a variation in voltage beyond a certain limit can occur at its terminals with a change in current. The diagram on this page shows the battery and dynamo connections.



SWITCHBOARD OF STORAGE BATTERY PLANT ON YACHT "INTREPID."



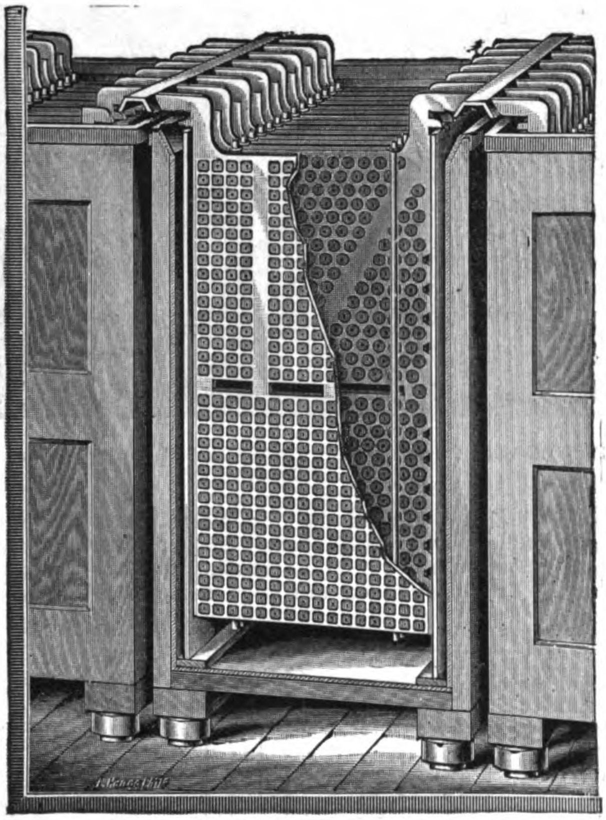
SWITCHBOARD CONNECTIONS OF STORAGE BATTERY PLANT ON MR. LLOYD PHOENIX'S YACHT "INTREPID."

THE STORAGE BATTERY IN FIRE ALARM AND POLICE TELEGRAPH WORK.

An important application of storage batteries that is in itself a specialty is that to municipal fire alarm and police telegraph systems. As an example of a first-class installation of this sort we may refer to that in the city of Wilmington, Del., which was installed under the supervision of Mr. John L. Hall. The battery here consists of 470 cells divided into eleven circuits fed by from 7 to 30 cells each, a duplicate set being provided for each circuit. These cells replace the same number of gravity cells.

The views on page 456 show one tier of the battery and illustrate the method of installation; also a front view of the switchboard and the back of a six-circuit board.

The current from the street mains enters at the double pole knife switch at the top of the board; thence after passing through a fuse and two automatic circuit breakers it is distributed to the charging circuits.



CENTRAL STATION TYPE "H" CHLORIDE CELL.

The discharging circuits enter at the bottom of the board through fuses, spring jacks and resistance coils. The jacks are of a special three-way form and allow of the simultaneous insertion of voltmeter and ammeter into the circuits. The resistance coils are employed to compensate for any change in the line resistance.

The battery circuits enter at the bottom of the board through transfer switches which enable them to be connected with the board, or not, as desired. From these battery switches the circuit goes to the main gang switches which transfer simultaneously all the circuit from one battery to the other of that set. All these operations as is essential in this class of work are performed without at any time opening the circuit.

Among the advantages of secondary batteries for this work may be mentioned their cleanliness, steadiness of potential, saving of floor space, small amount of attention required and, above all, their economy. At the Wilmington plant, it is estimated that there will be a saving of $1,200 per year over the cost of the old gravity cells.

A YACHT LIGHTING PLANT.

A typical installation of this type is that on the yacht "Intrepid," owned by Mr. Lloyd Phoenix.

The storage battery forms a practically indispensable adjunct to this plant. The elements are contained in rubber jars known as the "yacht type" because of the extra height desirable for this use. These jars are contained in lead-lined wooden trays built into the boat, of such shape and size as to best utilize the space available.

The switchboard controlling the operation of the plant is a marbelized slate panel 3 by 4 feet in size mounted in the engine room near the dynamo. This board contains all the necessary apparatus to perform the various operations of charging, discharging and lighting direct from the dynamo. See page 457.

The instruments are Weston round pattern. Regulation of charge and discharge is effected by a rheostat in the battery circuit. For the charge, the battery is divided into two sets which are put in parallel. The whole battery is in one series on the discharge. This is the usual practice in yacht installations in order to avoid the complication of end or counter cell regulation, and to avoid at the same time the use of a booster, or raising the dynamo voltage above that of the lights. The connections of the switchboard are shown on page 457.

The battery has a capacity of two hundred and fifty (250) ampere hours.

The installations we have described have been taken from among scores and scores carried out by the Electric Storage Battery Co., and the space at our disposal does not suffice to permit us to more than hint at other typical fields of the company's activity. Thus we might have gone into the now most promising storage-battery car work being carried out, an excellent example of which is the Englewood & Chicago Railway, on which road 30 storage battery cars have been running for over a year most successfully under all conditions of service met with in actual practice.

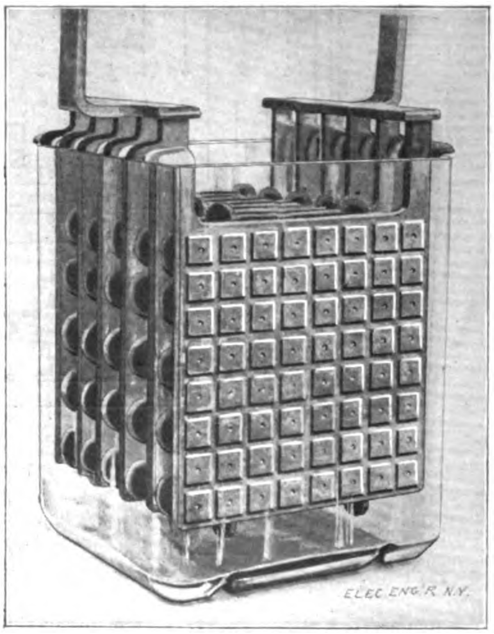
Then there is that fascinating means of marine propulsion, the electric launch, of which hundreds are now in operation all over the country; not to speak of those sent abroad and equipped in every detail on this side of the water.

And then there are the electric carriages now rapidly coming to the front, one hundred being in course of construction, to be added to the electric cabs now operating in New York.

To this already long list we might add the mention of the use of the storage battery in train lighting now being carried on extensively on the cars of the Atchison, Topeka & Santa Fé Railroad. And last, but not least, we may recall the use of the portable batteries for driving phonographs, kinetoscopes, automaton pianos—in fact, an endless number of miscellaneous applications requiring small power in handy form.

The engravings on this page give some idea of the general type of the Chloride cells in use. These range in weight from the 8-pound portable cell to the 6,000-pound cell, as installed in some of our large electric lighting and railroad power stations.

In drawing this narrative to a close the writer calls vividly to mind a visit paid to the same establishment about seven years ago. The difference in the factory activity at that time as compared with its present hum of business everywhere can be best conveyed to the reader by the statement that while at the period mentioned, about fifty men sufficed to carry on all the work



ISOLATED PLANT TYPE CHLORIDE CELL.

with ease, no less than three hundred men, aided by the most improved automatic machinery since developed, are hard pushed to keep up with the company's rapidly increasing business. That tells the story of the growth of the storage battery in America better than any statistics can do. At the present rate of increase, indeed, the figures of to-day may well be doubled within the twelve-month now passing.

THE COMPANY'S MANAGEMENT.

The personnel of the management of a concern whose product occupies such an important place in electrical work must always be of interest, being an index of its character and a guarantee of its stability.

Mr. Isaac L. Rice, the president, is a gentleman well known in financial and electrical circles. Mr. W. W. Gibbs, the first vice-president, scarcely requires an introduction to our readers; his early faith in the storage battery and his successful efforts in bringing under one control the principal patents relating to the storage battery art will be fresh in the minds of all.

OFFICERS AND STAFF OF THE ELECTRIC STORAGE BATTERY CO.

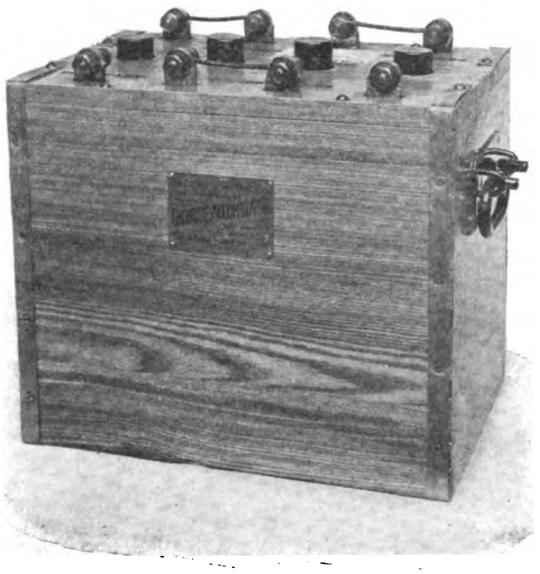
1. Isaac L. Rice.
2. W. W. Gibbs.
3. Herbert Lloyd.
4. Benjamin W. Tingley.
5. Joseph Appleton.
6. R. McA. Lloyd.
7. J. B. Entz.
8. John R. Williams.
9. C. W. Woodward.
10. J. B. Falkner, Jr.
11. Charles Blizard.
12. F. J. Stone.
13. W. O. Knudsen.
14. R. C. Hull.
15. F. H. Clark.

Mr. Herbert Lloyd, second vice-president and general manager

of the company, almost from the organization of the company in 1888, has had entire charge of the commercial as well as the technical development of the company's business. To Mr. Lloyd's abilities as a chemist and engineer, added to a high order of business ability—a rare combination—is due in no small degree the success of the company's business.

Mr. Benjamin W. Tingley has long served as secretary and treasurer of the company with great credit.

The company's Board of Directors is composed of the following gentlemen, most of whom are well known in the world of finance and industry: W. W. Gibbs, C. A. Griscom, Gustav E. Kissel, Joseph F. Sinnott, Edward Tuck, Edward C. Lee, John I. Waterbury, George Philler, W. D. Winsor, Herbert Lloyd, Rudolph Ellis, Grant B. Schley, Randal Morgan, Isaac L. Rice, Philip Lehman.



LARGE PORTABLE CHLORIDE ACCUMULATOR.

The principal offices of the company are in the Drexel Building, Philadelphia. For promoting the sale of its batteries, the country is divided into districts with a branch office in each district, the location of the various offices being as follows: New York, Boston, Chicago, Baltimore and Cleveland, and an agency on the Pacific Coast. The managers of the branch offices, in addition to their clerical force have the assistance of an engineer as well as a competent staff of experts who work under the direction of the main office.

SMALL PORTABLE ACCUMULATOR.

We present on page 459 the portraits of the principal officers of the company and of the technical and business staff. The names and locations of the latter are as follows: General Agent, in charge of the Sales Department, John R. Williams; Assistant, C. W. Woodward. Chief Engineer Construction Department, J. Appleton; Assistant, R. H. Klauder. Chief Engineer Railway Department, J. B. Entz. Factory Superintendent, Carroll Potter. Purchasing Agent, J. B. Falkner, Jr. Manager of New York Office, Mr. Charles Blizard; R. McA. Lloyd, Engineer. Manager of Boston Office, Mr. Frank J. Stone; J. Lester Woodbridge, Engineer. Manager of Chicago Office, Mr. Frank H. Clark; R. B. Daggett, Engineer. Manager of Baltimore Office, Mr. R. C. Hull. Manager of Cleveland Office, Mr. W. O. Knudsen. Agent for the Pacific Coast, Mr. A. E. Brooke Ridley.

In order to secure competent persons to install and operate the batteries manufactured by the company, graduates of the various schools of electrical engineering are taken into the laboratory at the company's works and trained in all the details of the business. After a laboratory course the young men are transferred to the construction department and eventually put in charge of a force of men employed in the construction of plants. In this manner the company is always assured that its work is in the hands of intelligent and trained men, and to that fact may be ascribed the high character of its work wherever installed.

LETTERS TO THE EDITOR

The Facts as to Aluminum and Copper for Conductors.

IN The Electrical Engineer of March 31, 1898, in an editorial entitled, "Aluminum versus Copper for Electrical Conductors," you refer to the discussion of Mr. Alex. Dow of the paper of Mr. Jesse M. Smith, before the Detroit Section of the Association of Engineering Societies, in which Mr. Dow claims that the increased diameter of aluminum wire necessary for equal electrical conductivity over copper wire would increase the stress along the approximately horizontal line, due to wind pressure; this stress being proportional to the projected area normal to the line of stress. In other words, his inference is that the increased diameter of aluminum wire would require a much greater transverse strength of poles or much heavier bracing against wind pressure.

This inference, however, does not take into consideration the fact of the very much decreased dead-load of the aluminum over the dead-load of the copper span of equal electrical conductivity. The facts in the case are that 48 per cent. of the weight of the copper will give a section of aluminum wire of equal electrical conductivity—that is, the section will be 100 for copper to 160 for aluminum, while the weight of the copper in any given length, say, 1,000 feet or a mile, will be as 100 of copper to only 48 of aluminum.

When this factor is taken into consideration, the strain upon the poles due to the use of aluminum line of equal electrical conductivity is found much less, even with the added wind pressure, than the copper line of equal electrical conductivity.

Mr. Dow in his discussion of Mr. Smith's paper claims that the added section of the aluminum line would have to withstand increased snow load. This is a matter which I am told by engineers who have had large experience in it, is not the case, as the snow load seems to be almost independent of the actual size of the suspended wire.

As to the tensile strength of the wires, the aluminum can be furnished with a tensile strength of 40,000 pounds per square inch, while the hard-drawn copper wire will have a tensile strength of, say, 65,000 pounds per square inch. The section of 160 for the aluminum to 100 of copper will have an equal, if not slightly greater, tensile strength for the line than will the copper; so that the facts which have already been proved, that aluminum lines of equal electrical conductivity will withstand both wind and snow loads superior to copper wire, can be proved by theory as it has already been demonstrated by practice.

In this connection, I would quote from a letter of March 14, received from Mr. D. H. Fitch, of the Telephone Exchange at Cazenovia, N. Y., as follows: "In regard to further use of aluminum wire, I shall have use for a little of it for special work this spring. All thus far used has done splendidly. I was a

little apprehensive of the last, on account of being so soft, but it has stood the storms thus far without the least impairment. The last put up were about 450 feet spans. The long span (nearly 600 feet) has now stood through two winters and is in perfect condition—just where I put it; has not stretched or sagged. I have an inquiry from Canada, which I herewith enclose. I have said to him that 'my use of aluminum is most satisfactory, and if I had this exchange to build to-day, I would use aluminum wholly for line work.' "

The writer is glad to acknowledge the great value that the development of the metallurgy of aluminum has received from electrical engineering, but respectfully maintains that it is not yet proved that the electrical engineering profession has not much yet to expect from the metal aluminum.

THE PITTSBURGH REDUCTION CO.,
Alfred E. Hunt, President.

Pittsburgh, Pa., April 15, 1898.

The Town of Hudson Has Had Enough.

The following I have clipped from the Boston "Evening Transcript," of April 16, 1898:

"The town of Hudson, which owns a municipal lighting plant, has concluded that it cannot sell electricity to consumers at a price on which it can make a profit, and so has petitioned the Gas and Electric Light Commissioners for permission to sell for less than cost. Its present price is 20 cents a kilowatt hour. No date has been set for a hearing."

Another demonstration, I take it, of the "business methods" of municipal management as exercised in electric lighting plants.

JAMES I. AYER.

Boston, April 21, 1898.

Liquid Air.

MANY articles have been written regarding liquid air in the last few months, and, like all new developments, there have been many erroneous or misleading statements made. It is a subject which opens up a vast field for the scientific investigator, as we have no data of any importance upon which to base calculations, and to use a common expression, it is a case of "cut and try." I have read several articles lately on liquid air, and nearly all contain statements not borne out by facts. As you are aware, Mr. Tripler has spent years of time and a great deal of money in the liquefaction of gases, and in the past few months he has very courteously shown his apparatus and the liquid air to the public. Articles have been written by persons who have no experimental knowledge and are not conversant with all the data, and the results are statements that are erroneous and misleading, and which are calculated to retard rather than assist the development of the subject. I notice an article in your issue of April 14 by an assistant professor in Adelphi Academy, Brooklyn, Mr. Sol. D. Benoliel, E. E., A. M. His description of the liquefying apparatus is radically wrong, as also is his statement regarding the number of horse power hours required to produce a gallon of liquid air. In the article, he has an illustration entitled, "Prof. Peckham's Vacuum Bulb." Facts will hardly credit the idea to Professor Peckham. If Mr. Benoliel will take the trouble to look up some of the back numbers of "Engineering" and also the "Engineer" of London, he will find that this form of bulb, together with several others, was made by Professor Dewar, before Professor Peckham ever saw liquid air. The assuming of such credits is very unprofessional and distasteful to readers who are conversant with the facts.

In the description of the experiments, courtesy would demand that credit should be given to the originators of these experiments, as nearly all of them were shown to Professor Peckham by Mr. Tripler. In the article in question, the statement is made that in changing a jet of steam into ice, it lost in an instant 1,290 deg. Fahr. This is erroneous, as the drop in temperature is only the difference between 212 and 32 deg. Fahr., or 180 deg. If he had stated that this was a loss of heat units it would have been nearer right. Space will not permit me to extend this criticism farther, but, knowing that a journal of the high standing of The Electrical Engineer always wants accurate data, I have taken the liberty of calling your attention to the above, that your readers may not be misled regarding a subject so important as liquid air.

W. H. DICKERSON.

Newark, N. J.

Electrical Steering Gear.

Referring to the description and drawings of the Pfatischer electrical steering gear, published in The Electrical Engineer of January 13, 1898, I have the honor to state that the apparatus described infringes directly on my patents 381,228, dated April 17, 1888; 385,229, dated June 26, 1888, and 387,714, dated August 14, 1888, as an examination of those patents will clearly show.

BRADLEY A. FISKE, Lieutenant, U. S. Navy.

U. S. S. Petrel, Hong Kong, China, March 6, 1898.

LITERATURE

MODERN SWITCHBOARDS. By A. B. Herrick. Cutter Electric and Manufacturing Company, Philadelphia, Pa., 1898. Cloth. 221 pages. 9 x 11 inches. Price, $3.00.

This book which may be called a compendium on switchboard construction from the beginning of the electric light industries up to the present time, is without a doubt the most complete treatise on switchboards and the appliances used thereon ever issued. It embodies a historical résumé of early practices and expedients, indicating the advance recently made in this class of electric apparatus, besides giving valuable data on improved methods of construction. The book is profusely illustrated by numerous cuts, drawings and designs especially prepared for this publication. The publishers acknowledge their indebtedness to Mr. L. Stieringer, Mr. A. B. Herrick, and Mr. W. H. Tapley for their valuable contributions. Following a very interesting introduction on the advance of the art of switchboard construction, are eleven chapters dealing respectively with circuit-breaking devices, switchboard construction, switchboard appliances, protective devices, low tension switchboards, low tension central station switchboards, railway switchboards, alternating current switchboards, arc light and special switchboards, circuit breakers and their use in power transmission, and an essay by Mr. W. M. Scott on the development of the circuit breaker. The book, though it is issued by a manufacturing company, is far from being solely an advertising medium and is a valuable addition to the electrical literature of the day. We heartily congratulate the Cutter Electric and Manufacturing Company on the production of this splendid volume, which has the two-fold effect of bringing before the electrical public their high grade apparatus, and educating the layman and student in this interesting and scantily understood subject.

THE CALORIFIC POWER OF FUELS. By H. Poole, F.S.C. Published by Wiley & Sons, New York, 1898. Cloth. 248 pages. Price, $3.00.

This book, which was commenced as a translation of M. Scheurer-Kestner's treatises on the calorific powers of combustibles, has undergone changes which became necessary to adapt it to American methods and data. The work embraces only that portion of calorimetric determinations having a bearing on fuel volumes; a concise description is given of leading calorimeters, those most commonly used being described more fully than others, and some examples of working and calculations are added. The book is well and amply illustrated and its chapters contain valuable data on solid, liquid and gaseous fuels, and the calorific power of coal burned under steam boilers. The book being based on American practice, should certainly commend itself to every power user in this country, and it may be said to fill a want which has long been felt by those interested in the generation and utilization of power.

OHIO having tried electrocution, now proposes to give up entirely the death sentence. This may serve as a pointer for Massachusetts, which is proposing to substitute gerrycide for hempen methods.

AM. ASSO. AD. SCI. is to meet in Boston in August and has just issued an interesting circular of preliminary announcements as to committees, sections, excursions, etc.

Vol. XXV. NEW YORK, APRIL 28, 1898. No. 521.

The Storage Battery Industry in the United States.

AMERICA has never been accused of lack of energy and enterprise in taking up and pushing to successful commercial application any method or device which gave promise of success. On the contrary, the rapidity with which it has created new industries is a matter of familiar history. The electrical arts, especially, have of recent years been the 'favorites upon which brains and capital have been lavished without stint in the United States, so much so, indeed, that this country has become the Mecca for all who would be up to date on the newer applications of electricity. But in justice to European electrical engineers one reservation must be made to the above statement, in so far as it relates to storage battery work. Indeed, it is but a short time back that the American electrical engineer desirous of keeping himself informed of the latest practice in this branch of electrical work was obliged to cross the ocean, a trip which indeed was made by not a few for the specific purpose. A long and dreary story might be written as to the causes that held the storage battery back so long in America, and to enter into it now would be a useless as well as a thankless task. Suffice it to say that the storage battery no longer requires any apologists on this side of the water, and that the American engineer need no longer undertake a trip abroad to study the storage battery question. This happy state of affairs, brought about within the past few years, is surely a subject for congratulation, and vindicates the position long since taken by The Electrical Engineer, that the storage of electrical energy offered one of the most potent means of overcoming the drawbacks under which many of our central stations were, and still are, laboring. Stronger than ever in our belief that the storage battery has a most important mission to fulfill we have in this issue placed before our readers a description of plants typical of the many applications where such an adjunct to the dynamo is not only conducive to economy, but in most cases indispensable. As to the future, one is naturally inclined to look for the bulk of the storage battery work within the confines of the central station, and this anticipation is fully justified by the experience of the past. But a closer study of recent practice, more particularly abroad, would seem to indicate that, after all, there are situations outside of the central station building itself, where the storage battery may be operated with considerable economy, from the standpoint of both the electric light station and the consumer.

It makes little difference evidently, viewed from the electric standpoint, whether the storage battery which equalizes the station load is located within the central station or on the premises of the consumer. But it does make a good deal of difference whether the central station has to pay for the storage battery, or whether the consumer pays for its installation. It must be plain that if the latter be the case, the central station is relieved of a heavy item of expense, for which it ought in justice to the consumer, compensate him in some way or another. This is the principle on which the Berliner Elktricitäts Werke have recently inaugurated a new system, which bids fair to become a pronounced success and to add greatly to the popularity, as well as to the earning capacity of that admirably managed company.

The plan adopted is to urge consumers to install local storage batteries on their premises, which are charged at certain specified times indicated by the company; in this way, by distributing batteries on its circuits, and charging them at scheduled times the load on the engines at the central station can be regulated in such a way that they are practically always running at maximum efficiency.

The normal rate of charge at Berlin is fifteen cents per kilowatt hour, but to encourage the installation of local storage batteries by consumers, the company makes a reduction of close on to 75 per cent. in its rate of charge, so that the actual cost for charging local storage batteries at specified times, is only four cents per kilowatt hour. Startling as this proposition may appear at first sight, we believe that when gone into carefully, it will be found to be thoroughly sound; indeed the mere fact, that so conservative and well managed a company as that at Berlin has adopted this system is sufficient proof that it is a thoroughly practical one.

The record of the storage battery work as described in the typical plants illustrated in this issue, would not be complete without mention of the company which has successfully accomplished the up-hill task of establishing the storage battery on a firm footing in this country. We feel certain that no one will begrudge The Electric Storage Battery Company the credit which is due it, as the pioneer in this department of work, and we are glad to believe that as a result of its intelligent and conscientious efforts the storage battery is now meeting with very full appreciation at the hands of American electric engineers and central station managers.

Practical Uses of Liquid Air.

THE numerous interesting and novel experiments shown of late with liquid air and the description of Tripler's and Linde's method of producing the cold necessary to liquefy air, have, besides awakening interest in this new and marvelous product, opened up the question as to its possible practical uses. No one of course can at this early stage, the period of experimentation, predict the benefits which mankind may derive from this marvelous laboratory production. However, several uses of liquid air have already been outlined, which, if realized, will bring about a revolution in many important industries of the day. In the first place it is not unlikely that in the manufacture of chemicals or explosives liquid air may find practical application, but the two most important uses to which it will probably be put are refrigeration and the storage of power. It is not to be supposed, however, that liquid air will replace ammonia for refrigerating purposes in the near future, as the ammonia refrigerating machine has a very high efficiency; but for special purposes where very low temperatures are required and where it is desired to confine the refrigeration to a small space, liquid air may soon find extensive application. The most important by far, however, of the probable future uses of liquid air appears to be the storage of power. This problem was discussed at length in a recent issue of "Engineering News," from which the following deductions are taken: Of all the methods known to engineers for the storage of considerable power with apparatus of moderate weight and bulk, only two, the electric storage battery and compressed air tank have been commercially developed of late. The new method of using liquefied air, while it is more expensive than the older systems and returns a smaller percentage of the power originally applied, possesses the great advantage of storing many more foot pounds of energy in a cubic foot than any of the systems with which we are familiar. First let us see what advantages liquid air has over the compressed air system as a means for storing power. In the latter system the air is stored under pressures of about 2,500 pounds per square inch. This necessitates the tanks to be made very heavy and the weight and bulk of these tanks are a great drawback to the commercial adoption of this system. Liquid air, however, occupies only one-fourth the space of air at the above stated pressure, and, if the tank containing it is properly jacketed, it can be kept for a considerable time. A safety valve might be

attached to the tank to prevent the pressure from exceeding a certain amount. This economy in space and weight compared with the storage of power by means of compressed air, and the application of a reducing valve so that it can be used at any desired pressure, will at once be manifest. Comparing liquid air with the battery as a means of storing power, it may be stated that a pound of battery stores from 8,500 to 15,000 foot pounds, or about one-tenth to one-twentieth the power that is stored in liquid air. The storage of heated water as a means of power storage compares most unfavorably with liquid air storage; the latter storing about four times as much power for a given weight as the hot water or stored steam system. It should be stated, however, that in all the above mentioned systems the amount of power which may be obtained from a pound of the substances employed is considerably less than that which may be obtained from a pound of any good fuel used in the steam and gas engine for the development of power. While the above comparisons of the various systems certainly places the use of liquid air far ahead of all other known systems, still the employment of it for the storage of power is a possibility of the future rather than an attainment of the present. Much will depend on the efficiency of production and the reduction in the cost of the material. The success achieved, however, points to an early application of liquid air for torpedo propulsion, where cost is a secondary consideration, as well as for the propelling of motor carriages and bicycles where the main consideration is the maximum storage of power with the least possible space and weight.

So much for the use of liquid for the storage of power. Another already commercially practical application is to make an explosive by mixing liquid air with carbon. In a recent lecture before the Society of Arts, Prof. J. A. Ewing gave a very interesting account of the details of the process of manufacture employed by Dr. Linde. The explosive obtained by mixing liquid air, enriched by the evaporation of a large part of its nitrogen, with powdered charcoal, compares in power with dynamite and can be made to go off violently by using a detonator. Cotton wadding impregnated with coarse charcoal powder can take up more than enough liquid air to supply oxygen for its complete combustion and when put quickly into thick insulating cases, made of paper, the explosive power is retained for five or ten minutes. According to the size of the cartridge all this power is lost after an interval varying from fifteen to twenty or thirty minutes. For several purposes this is a decided advantage. On account of the low temperature produced by the explosive which is lower than that required to ignite fire damp, the process has been commercially used in some coal mines in Germany and has been found very satisfactory.

The Value of Exhibitions.

ACTIVE preparations are going on this moment for the Electrical Exhibition, which is to be held next week in Madison Square Garden, and a fine spectacle will be in readiness for the opening exercises of Monday night—exercises which even in these times of war, both the President and the Vice-President of the United States deem important enough to take an active part in, with the intervention of the phonograph, telephone and telegraph. In fact, the existence of war does but emphasize the importance of the electrical arts, for vital functions on our warships, the defence of our harbors and maritime cities, and the patrol of our coasts all depend upon the efficiency of apparatus now to be illustrated. There is, moreover, the other national side to our electrical development, and that is the exemplification in this exhibition of the peaceful apparatus which in growing quantity and value this country is now exporting to all parts of the world. We all know that such a splendid collection of manufactures is what appeals most of all to our noble President, who has spent his life in the endeavor to build up American industries, and who in these latter months has stood out with such magnificent endurance and patience as the exponent of American desires to conquer, not by force of arms, but by reason of humanity, pity and charity.

It is natural that at such a juncture some people should wonder at the courage with which the management of the Exhibition has carried through its great task. There are always those who can throw cold water on an enterprise, impugn the motives of its promoters, hint cynically at its failure, and even do a little to check natural success; and at such periods of crisis as this, a little detrimental effort goes a long way. We venture now to express our belief that the Exhibition will be one of the most brilliant and successful ever held in this city or this country. So far from the war hurting it, we think the effect, so far as attendance and results go, will help it, and that it will be during the month not only a patriotic rallying point, but a centre of the very latest news from the front, illustrative of the facilities afforded by electricity for the swift transmission of intelligence. As was said last week in the New York "Evening Post": "There is always a tendency in war time to a reactionary excess of exciting amusement. The old home life about an evening lamp, of books and music, and family and neighborly recreation, has never returned to us as a people since the long-drawn-out distress of 'the rebellion.' The theatres overflowed, and men loved to congregate together and discuss the questions of the day; the result has been lasting upon all phases of society. Men and women prone to seek causes for social changes can clearly say, 'This came to be the custom since the war.'" The Electrical Exhibition, coming at a time of the celebration of the Greater New York Day, and at a period when war is waging after thirty years of peace, will be but one more proof of the social phenomenon above noted.

But turning to the practical point, the value of exhibitions, it can only be said that they have various desirable features and many undeniable merits. So long as merchants find it profitable to expose their goods for sale in store windows and warehouses, and so long as the public flocks to see such goods, there can be no question as to the justification for holding exhibitions. Just as women go from store to store, however, comparing qualities and prices, so on the other hand people go to an exhibition knowing that they are saved all the toil of such slow processes, and that in a glance and in a brief space of floor and time they have submitted to them all that is latest and best. In addition, they are impressed when they see a number of large and active concerns all putting forward certain specialties or tending rapidly towards standardization in apparatus of whose existence and uses they had hardly any idea. If at all in a position to need or introduce such apparatus, they receive an irresistible impulse to marshal themselves also in the onward movement—and thus the good work is accomplished. It is a matter of absolute record that many notable and great advances in the arts and industries owe great strides to the opportunities afforded by exhibitions to impress and convince the public.

Exhibitors also gain more than they are aware of from their participation. They are apt to say sometimes that they "go in" because another concern does, and that a self-denying agreement to stay out would really be beneficial. This begs the question, for no man who wants to get at the public waits upon other concerns, as to his intention and ability, when it comes to trade literature, advertising, sending out salesmen, or putting up his wares attractively. Besides, the neglect to avail of the opportunity presented by an exhibition often has a bad effect upon a concern, directly and indirectly. Getting ready for the show induces to better effort, things that were dragging are pushed to a finish, what was shown last time has to be excelled; and in one way and another, an exhibit comes to mark a new point of departure from which progress can be gauged and tested. Relatively, also, the man who goes in gains doubly by the abstinence of the man who stays out, and we know of instances where that fact, being realized at a late moment, the absentee has spent far more money than an exhibit would have required, in endeavoring to "hold his end up" in some offsetting manner.

The Exhibition is now upon us, and this article will barely have been read before the Garden will be thronged by crowds of the curious, the wealthy, the young and the progressive in all classes of society, not to forget those who represent the art itself. The management has done wisely in securing the co-operation of the New York Electrical Society, which has lent itself enthusiastically to the work; and in providing for visits of the scores and scores of chapters of the National Association of Stationary Engineers, so that some six or seven thousand picked men operating modern steam and power plants will be brought into direct, close touch with all that is latest and best in electrical development. In other educational ways, with lavish liberality, the management has provided features of attraction and instruction, and we rest confident of the results.

Municipal Electric Lighting.[1]—X.

(Concluded.)

BY PROF. JOHN R. COMMONS.

OPERATING EXPENSES OF MUNICIPAL AND ELECTRIC PLANTS.

Below, I have compared the operating expenses of the two largest American municipal stations which have published the records of their output in kilowatt hours, with the four cities, Glasgow, Manchester, Dublin and Aberdeen, and have also inserted Foster's estimate for the fourteen American municipal stations noted above in Table V, and his citation of Crompton's English stations. The high labor cost of the American stations is noticeable, but notwithstanding labor in Allegheny and Detroit is 145 per cent. and 152 per cent. higher than in Manchester and Glasgow respectively, and the cost of fuel is but slightly different, yet the total cost for the American cities is but ten per cent. higher than that of the two model British municipalities, and but little above Crompton's ideal English station. The smaller American municipalities, although bearing nearly double the labor cost, have a total cost less than five per cent. above the twenty-three English stations.

TABLE XV.

COMPARISON OF OPERATING EXPENSES PER K.W.

	Year ending	Total k.w. generated at the station.	Labor.	Fuel.	Supplies.	Repairs.	Office.	Miscellaneous.	Total.

IMPORTANCE OF COMMERCIAL LIGHTING.

The foregoing comparisons have dealt mainly with American street plants. But it is an unfair comparison which looks mainly at street lighting. Even more important is the relief of the private consumers from exorbitant charges. Incandescent lighting can be furnished at ten cents per kilowatt hour or one-half cent per lamp hour—one-half the usual private rates—and yield a large profit to the municipal plant. At this rate it is cheaper than gas and more wholesome and convenient. Besides, electrical power can be furnished at much lower rates. The only failures of municipal plants hitherto reported are those which furnished street lighting alone, and the so-called greater success of the private companies which took the place of the municipal failures has been based on their commercial business. One or two examples will show the great importance of this side of municipal lighting.

Jamestown, N. Y., operates 275 street lamps of 1,200 candle power each an average of six hours per night or 2,200 per year, and 1,200 sixteen candle power incandescents in alleys and public buildings. The latter at three hours per night are equivalent to 100 arcs making a total of 375—1,200 candle power arcs. The operating expenses and insurance are $19,122.16; interest on bonds ($72,000, at four per cent.), $2,880; lost taxes and depreciation on cost of plant ($74,000, at four per cent.), $2,960; total cost $24,707.16. The commercial income from 1,500 lamps is $5,913.89, leaving a net cost to taxpayers for public lamps of $19,028.27 or $50.79 per year, or $.0231 per lamp hour. The only other cities of New York reported in Johnson's "Electrical Directory" as having 1,200 candle power street lamps are the following: Elmira—335 lamps at $102.20 per year, all night, every night, $.0281 per lamp hour. Middletown—32 lamps, at $108, all night, every night, $.0293 per lamp hour. New Brighton—100 lamps, at $100, all night, every night, $.0274 per lamp hour. Not considering that the cost per lamp hour should be much less where lamps are burned ten hours instead of six, the cost to Jamestown is one-half cent per hour less than in the other cities or eleven dollars per year per lamp, a saving of $4,125. The commercial customers of the city pay $6,000 per year which is a saving of $3,000 for them as compared with their former payments to the private company. Further, the private company still furnishes 10,000 incandescents, 188 arcs and 200 horse power, on which the reductions in charges have been fully $10,000 and probably $20,000. The total saving to the city therefore has been probably $25,000 yearly.

Lansing, Michigan, pays its municipal plant $10,000 yearly for 117-2,000 candle power lamps, moonlight schedule, all night, and the plant receives also $15,000 for private lighting, making a profit for the plant of $7,000 yearly above operating expenses and interest. The rates are twelve cents per kilowatt, being a reduction of eight cents below the rates charged by the private company whose plant the city purchased. The saving to the citizens on commercial lighting is therefore approximately $10,000 per year.

PRIVATE OWNERSHIP PRODUCES CORRUPTION.

The foregoing statistical comparisons may be taken as indicative that the great majority of the 200 or 300 cities and villages now furnishing light are actually getting better service at less cost than those which depend upon private companies. It is objected that such cannot be the case, especially in our large cities, because of the flagrant municipal corruption and inefficiency. Business ability and integrity are excluded from municipal office, appointments are made as a reward of political service, and the municipal plant soon becomes burdened with barnacles who draw pay without work. I do not deny that such is often the case. But I maintain that nine-tenths of the existing municipal corruption and inefficiency results from the policy of leaving municipal functions to private parties; and that an essential part of the present unparalleled awakening of civic conscience on the part of all classes of the people is the desire for municipal ownership of franchises. As the people become aroused to the degradation of their politics and the need of reform, their attention is concentrated on the chief source of that degradation, the under-handed and often high-handed domination of city officials and machine politics by the corporations whose life is maintained by city franchises. It is from them that the politicians get their campaign funds. Contrast the results of municipal ownership above given with the following:

In a city of 100,000 population a private company is organized in the early days of electric lighting with a capital of $100,000 supposed to have been actually paid up. In 1889 the company is "reorganized," increasing its capital by $130,000, $50,000 of which is for a "license" to use incandescent lights which it had already been using for several years, selling the entire increase in capital at from ninety to par. It has a contract for municipal lighting at $144 per arc per year, but has no definite franchise for private lighting. In 1890 a new company of eminent and respectable citizens is organized, at the head of which is the "boss" of one of the political party organizations. This gentleman has associated with him nine prominent citizens who control the avenues of public opinion, all the newspapers, directly or indirectly, and both political parties. They come before the Common Council promising cheaper light. They get a franchise from the aldermen by well known methods. They invest only enough money to erect two or three poles and so hold their franchise. They then make overtures to the old company which again is "reorganized." This time the capitalization is increased to $1,640,000 in stock and bonds, of which $400,000 in stock is given to these ten respectable citizens who procured the franchise, and $750,000 of which is in bonds at six per cent. interest, making a fixed charge of $45,000 in interest yearly on a plant that could be duplicated for less than $1,000,000. Here is a case where ten of the most respectable business men and lawyers of the city have placed their pecuniary interest in direct antagonism to good and honest government. They have become the powerful opponents of all public spirited officials who attempt to get fair terms for the city in this par-

[1]Municipal Affairs, Dec., 1897. A Reply to R. R. Bowker. See Elec Engr.

ticular business of controlling the supply of electric light and power, and no matter how they may afterwards "reform" and demand honest government, the people at large have learned to discount what they say and to distrust their efforts in subsequent movements for civic reform. Strangely enough, two or three of these very same men, being appointed without salary to positions on the Board of Water Commissioners to construct and operate a water works plant owned by the city, exhibited the very highest integrity and patient industry in promoting the city's interests and constructing a plant of which the citizens are justly proud.

We may call upon our eminent business men to arouse from their lethargy and to take an active part in municipal reform, but so many of them have been mixed in these "jobs" that the people at large have no confidence in their leadership nor in any candidate for office whom they are known to advocate. Such business men need reforming themselves, but this is to be done, not by appealing to them after the method of the revivalist, but by removing temptation from their way and giving them an opportunity to really serve the community in a public and honorable way through the employment of their distinguished business abilities. Private ownership of municipal monopolies forces them and all whom they can influence to oppose the good of the city. Municipal ownership makes it to their interest to place their abilities at the service of the city and to take an honest pride in the good they can contribute to it.

I do not for a moment deceive myself by thinking that this movement for municipal ownership is child's play, or that the companies now in possession will relinquish their hold without resorting to the most determined and unscrupulous devices. There are many indications that they are organizing throughout the country for an attack both upon municipal ownership and upon the integrity of municipal officials.

These concerted and unscrupulous attacks upon municipal integrity need not be looked upon as discouraging. More than anything else they will arouse the common people from their lethargy, and will disabuse them of their fond reliance on mere respectability as a guaranty of public spirit, will direct their attention to the true source of municipal corruption, and will discipline them in organized resistance and in aggressive movements upon the citadel of the corruption funds. In the end this discipline and organization will be the guaranty of efficient administration when once ownership is obtained. It is only in those cities like Detroit which have had a hard training for several years in open battle with the franchise holders, that we may look for that alert public spirit and jealous determination which will make municipal ownership a lasting success.

ADMINISTRATION REFORMS RECOMMENDED.

It is this struggle with monopolists, too, which will force the people to the adoption of administrative machinery better adapted to municipal operation of industry than any that we now have. It must be confessed that the legal organization of our municipalities is not yet perfected for the espousal of public ownership on any large scale. The experience of English and many American cities indicates the following administrative reforms as necessary to accompany or precede municipal ownership.

1. State supervision for cities, similar to that of the Local Government Board of England or that of the Board of Gas and Electric Light Commissioners of Massachusetts or of the Public Examiners of Minnesota and Dakota. A State Municipal Board like that proposed in New York by the Commission on Cities of the Third Class, would prescribe that most important requisite, uniform methods of municipal bookkeeping, would audit accounts of cities, and would direct the proper entries for new construction, depreciation, etc. Such a board would sanction loans and set the terms of years for repayment and the provisions of a sinking fund. In this way the constitutional limitation on municipal indebtedness could be replaced by a more elastic limit, on the principle that the acquisition of a productive property is really a lessening of the city's net debt instead of an increase. The board would publish annual reports giving details concerning finances, costs of production, revenues, etc., of the various cities, thus furnishing the basis for intelligent improvement in administration and for further acquisition of municipal plants.

2. The substitution of unsalaried Municipal Boards or Commissions instead of the Board of Aldermen as the administrative head. These boards should be composed of five or six members elected by the people or appointed by the mayor, one member to be chosen each year for a term of five or six years, thus giving continuity of service. The legislative branch of our cities has so hopelessly decayed that, until something like proportional representation is adopted, no additional powers should be granted to it. The successful electrical plants throughout the country in larger cities are under control of commissions. Wherever the spoils system and corruption exist we may expect to find the aldermen in control.

3. The Referendum and Initiative. The referendum is already universal upon all questions of purchase or installation of a municipal plant. It should also be required along with the initiative upon questions of the sale or lease of a plant, and the appropriations for improvements. Had it been in force in Philadelphia, it is needless to say, the recent scandalous lease could not have been consummated. Councils of that city refused to submit the question to the people although earnestly petitioned to do so by the Municipal League. The obligatory referendum is also necessary as the only thorough means for banishing bribery and the corrupt use of money from municipal politics.

4. A civil service reform system in which the superintendent or electrical engineer at the head of the plant should be appointed on merit and held personally responsible, and then should be entirely free to appoint and remove all subordinates without interference from an outside civil service commission. This is the practice generally where a board of commissioners, instead of the aldermen or mayor, has charge of the plant.

TELEPHONY AND TELEGRAPHY

The New Building of the N. Y. and N. J. Telephone Company, Newark, N. J.

ONLY a few weeks ago we had occasion to describe and illustrate the magnificent new exchange building of the New York and New Jersey Telephone Company in Brooklyn, N. Y.,

NEW EXCHANGE OF THE N. Y. AND N. J. TELEPHONE CO., NEWARK, N. J.

at which time we called attention to the rapid and phenomenal growth of this company. Not alone in Greater New York, but in New Jersey as well, has the company made rapid strides and outgrown its quarters which afforded ample room a few years ago. Another evidence of its growth is furnished by the news that within a month work will be started on the com-

pany's new exchange in Newark, N. J. This edifice, shown in the illustration, will stand on the site of the present quarters, 158-162 Market street. It will have a frontage of forty-eight feet on Market street and a depth of ninety feet. It will be three stories in height and will be so constructed that three additional floors may be added without interfering with the tenants or the business of the company. There will be two store fronts with the entrance between them. The second floor will be divided off into private offices. On the third floor will be the offices of the company. The material will be fancy mottled brick, with terra cotta and stone trimmings. It will greatly enhance realty values in the neighborhood of Broad and Market streets and altogether will be an imposing structure, which will combine utility with architectural beauty and stability. Its interior has been especially planned and arranged to accommodate and expedite the work of the various offices and departments of the company whose business it is to afford oral intercommunication between the thousands of Newark's business men, and those of the thriving suburbs which surround it on all sides, and between hundreds of private homes in this metropolis and other neighboring cities.

Practical Features of Telephone Work—VII.

BY A. E. DOBBS.

GUYS, BRACES, ETC.

Poles on curves and corners need to be well guyed or braced, for if there is one thing which is more aggravating than any other, it is to have the wires continually getting slack, because the corners give way.

The proper method of guying is, however, the sticking point with some otherwise good construction men. Figs. 17, 18, 19, 20 and 21, show the various correct and incorrect methods of

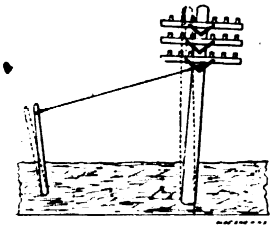

Fig. 17.

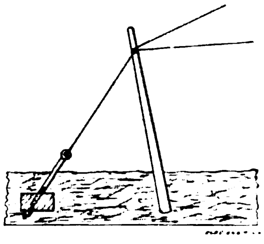

Fig. 18.

holding corner poles in place. In Fig. 17 we have a method of guying often seen, but none the better for all that. No matter how often the wires are pulled up around this corner they will get slack, for the stub will keep yielding to the strain, even though it is seven feet in the ground. The dotted lines show the original position of pole and stub. The guy is placed under the third arm, and the top of the pole itself will spring over several inches. The guy should have been placed just above or just below the top arm, or better still, two guys, one at the top and one below the lower arm. In putting guys on a pole, always place them so that the arm will be free for removal at any time.

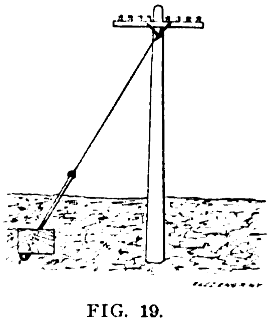

FIG. 19.

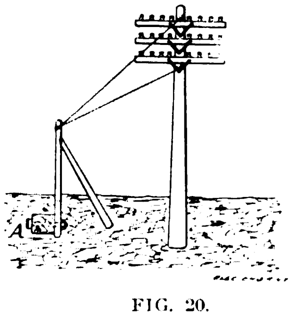

FIG. 20.

In Fig. 18 we have the most approved way of anchoring a stub so that it will stay. The anchor is a heavy block at least 4 feet long, and buried from 4 to 6 feet deep (a railroad tie makes a good one), from which a heavy iron rod is brought to the top of the ground. If rocks are plenty, weight it down with them and tamp the dirt solidly.

In paved streets it might be well to fill in a foot or two with cement concrete.

In Fig. 19 is shown another method of guying, and the pole shown in Fig. 20 will hold, but in order that the back stub may not pull out, a cross piece about the weight of a railroad tie, and three feet long, should be buried about 3 or 4 feet in the ground and bolted to the stub at A.

In some places where the pull is heavier than usual, as at the terminals of cable spans, etc., the guy may be extended

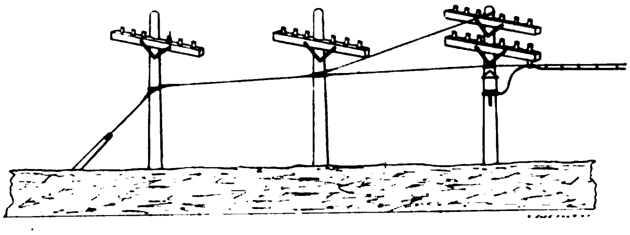

FIG 21.

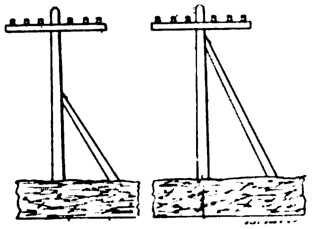
back over two, three, or even half a dozen poles, and finally anchored, as in Fig. 21. If the pull on the guy is severe enough to mark the poles, a strip of galvanized sheet iron will prevent it, if placed underneath the wire.

These spans should be cut off and made up separately for each section, so that there will be no giving away at any part.

In going through the country, No. 6 wire or even No. 8 will be sufficient for all ordinary purposes, for if a heavier guy than a single strand is needed, two or more wires can be twisted together. Some companies use nothing but No. 9 wire for this



FIGS. 22 AND 23.

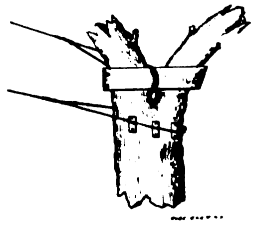


FIG. 24.

purpose. For anchors to stubs, 8 strands are twisted together, while for heavy corners one or more of 4 strands each are used. Cables of this kind can also be bought from dealers. In Figs. 22 and 23 are shown bad and good methods of bracing. In some places the only available places to guy is to neighboring trees. If these trees are shade trees the chances are that their owners will make objections, but the guys can be placed in such a way that the tree will not be injured, if made as shown in Fig. 24.

Where a tree fork is to be had, the method shown in the upper guy is best, the wire being simply fastened to a block and placed in the crotch. If this cannot be done it is better to place it around the tree in a single loop and place blocks behind it. Never pass a wire around the tree so as to compress it since the growth of the tree will be stopped, or the tree will be injured in a year or two.

In "making up" a guy at the ends there are two or three

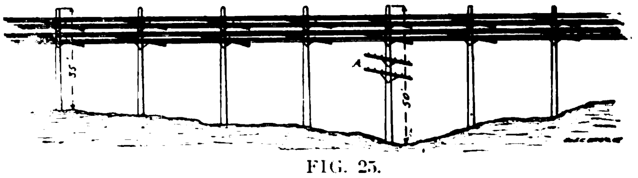

FIG. 25.

things worth remembering. One is that a splice made two feet from the point of support will be stronger than if made closer, and it also affords a chance to twist the wire and take up the slack between the blocks and point of support. Two inches can sometimes be taken up in this way.

In making up a cable, spread out the wires at the ends and twist them all in flat together. This will not only make a neat job but a much stronger splice than any other. The American Bell Company and some street railroad companies often use a clamp for this purpose, which is composed of two grooved pieces of iron drawn together by bolts which clasp the wire. Where guys are expected to stretch and give a little—as they

will in zero weather—a turn buckle will allow them to be taken up or let out as may be necessary.

As regards grading a pole line there are men who take pride in that sort of a thing, putting short poles on top of a hill and tall ones in the low places. One manager who likes this kind of work and having plenty of poles of all lengths, surveyed his line before building, and the result is a line like that shown in Fig. 25. In this sketch poles varying in length from 35 to 50 feet are graded to a level. The point, A, on the 50-foot pole shows how the line would look if the poles were all the same length.

The Cost of Niagara Power in Buffalo.

BY DR. C. E. EMERY.

REFERRING to the article on this subject in the Engineer of April 21, 1898, I am gratified to find that the charges for electrical power in Buffalo have at last been reduced to a rational basis. They are still too high to expect any enormous increase in the number of consumers, but the basis is such that business can be done by the usual commercial system of discounts.

The original proposition to charge for all power on a twenty-four hour basis, though most of the consumers could only use it for ten hours, was grossly inequitable. The company soon found that companies or customers were not anxious to obtain power delivered in the outskirts of the city, as was at one time proposed, and it is at this late day that it has been decided to take good advice, which by the way, was given them long ago, and bring the power to the customers in quantities and wherever required.

The idea of a fixed charge for service, independent of a pro rata power charge, is correct in principle, was initiated by me in the first sales of steam in New York, and has been accepted as sound by the electric lighting companies. The sliding scale based on the average quantity used during the month is also equitable. There remains therefore only the question of price.

The charges of $50 and $40 for twenty-four hour power to the Buffalo Traction Company were reasonable, and made it for their interest to take a large block of steady power but under the old ruling we know they were careful to provide for their variable power with steam. The new rule will in part overcome the difficulty, but the comparison for the multitude should be based on ten-hour power, or, say, 3,000 hours per year.

Let us see what the new prices mean, on a safe basis, that one kilowatt hour will produce one net horse-power per hour.

The $1 per month or $12 per horse-power per year for "service" based on the power the user requires kept available for him, that is, on the maximum power he requires, will, if his average power is two-thirds of the maximum, be a constant charge of $18 per horse-power per year for his average power. If the power factor be $^9/_{10}$, this charge becomes $13.33 per horse-power per year.

The energy is to be delivered as electric current, not as power, therefore the consumer must put in his own interior connections, high tension motor, or more generally transformers and motor, at a cost which should be less than $20 per horse-power for large installations, and may amount to $40 per horse-power for small installations and distributed power. Allow, say, $2 to $4 per horse-power per year, or 10 per cent. on the above for interest and depreciation.

Starting with the smallest item given in table of costs, 1,000 k. w. hours per month would give 4 horse-power for 25 days of 10 hours, or 250 hours. At 2 cents per unit (namely, k. w. hour) each horse-power will cost for electric current (3,000x $0.02=) $60.00 per year. Adding interest, $4, as above and for cost of service if 50 per cent. extra power is to be kept available as above, namely, $18, we have as the cost per horse-power of 4 average horse-power $82 for a year of 3,000 hours, which is not at all unreasonable for that amount of power if some saving of labor results compared with steam power.

Comparing the largest item given in table of costs: 80,000 units per month is equivalent to 320 horse-power for 250 hours. One horse-power at 0.66 cent per horse-power hour will for a year of 3,000 hours cost $19.80 for current. Adding $2 for interest and $18 for service, with 50 per cent. of power kept in reserve, makes the total cost $39.60 per horse-power per year, and for only 10 per cent. kept in reserve $34.80 per horse-power per year. If a saving of labor resulted compared with steam power there would be a slight inducement to pay the smaller price for 10-hour power. For power varying greatly, steam would be cheaper. The company is already selling 24-hour power at the higher rates, though in larger blocks. However, where the heat from steam boilers or the smoke from chimneys is undesirable, of course electricity will be taken at almost any cost.

Before the business is made a success the company must realize that it is necessary to deliver power, not current. That is, they must themselves install the motors and the transformers if high tension motors are not used. The company could generally do this work for less than $20 per horse-power and charge interest on the capital invested. If the consumers are left at the mercy of the trade there will probably be $40 expended per horse-power for the small installations and frequently as much for the large. Moreover, if the business of the consumer ceases, as happens frequently, the motors in his hands will not be available assets at full price, whereas in the hands of a supply company they will be practically as good as new stock.

With this very evident and simple change and a proper scale of discounts, particularly for the higher powers, we should begin to see sales of considerable electric power in Buffalo at points convenient to the distributing stations. Parties served from the original stations of course cannot fare as well.

A 1000 Horse Power High Voltage Transmission Experiment at Odgen, Utah.

IN interesting experiment in high voltage long distance electric power transmission, pregnant with influence on all transmission work was recently made at Ogden, Utah, in order to ascertain the limits within which high voltage currents might be used commercially. The experiment was made by Mr. F. O. Blackwell, of the General Electric Company, over the lines which connected the great power station of what was, until recently, the Pioneer Electric Company at Ogden, with the distributing circuits at Salt Lake City, and consisted in connecting the Salt Lake ends of the transmission lines together and dividing the transformers at Ogden, normally used for raising the pressure of the current for transmission, into step-up for the outgoing current and step-down for the incoming. The distance from the power station at Ogden to Salt Lake City is about 36½ miles. Making a complete circuit of the outgoing and incoming lines, therefore, with Salt Lake City midway, gave a complete transmission circuit of 73 miles over three No. 1 wires. The amount of power transmitted amounted to 1,000 horse-power, and the voltage at which the transmission was effected reached at times as high as 30,000 volts. The current on the return was delivered to resistance vats at the power house, consisting of three wooden tanks.

By careful and repeated measurement with wattmeters at both ends Mr. Blackwell ascertained that this power was transmitted with the loss of only 9 per cent., including 4 per cent. loss in the two sets of transformers. The drop in pressure due to inductance was practically nil, the capacity of the line being sufficient to compensate for reactance loss.

Continuing the experiment, part of the Salt Lake City station load was run from Ogden, with current at 24,000 volts. This was supplied to about 500 horse-power in synchronous motors and lights for two days, under most severe climatic conditions—rain, fog and snow alternating. In addition a severe thunderstorm prevailed all through the night; the lightning arresters discharging repeatedly. Notwithstanding the severity of the conditions under which the test was made, the motors operated without failure and the lights burned without flickering even during the times of lightning discharges. Not the slightest difficulty of any kind developed while this experiment lasted.

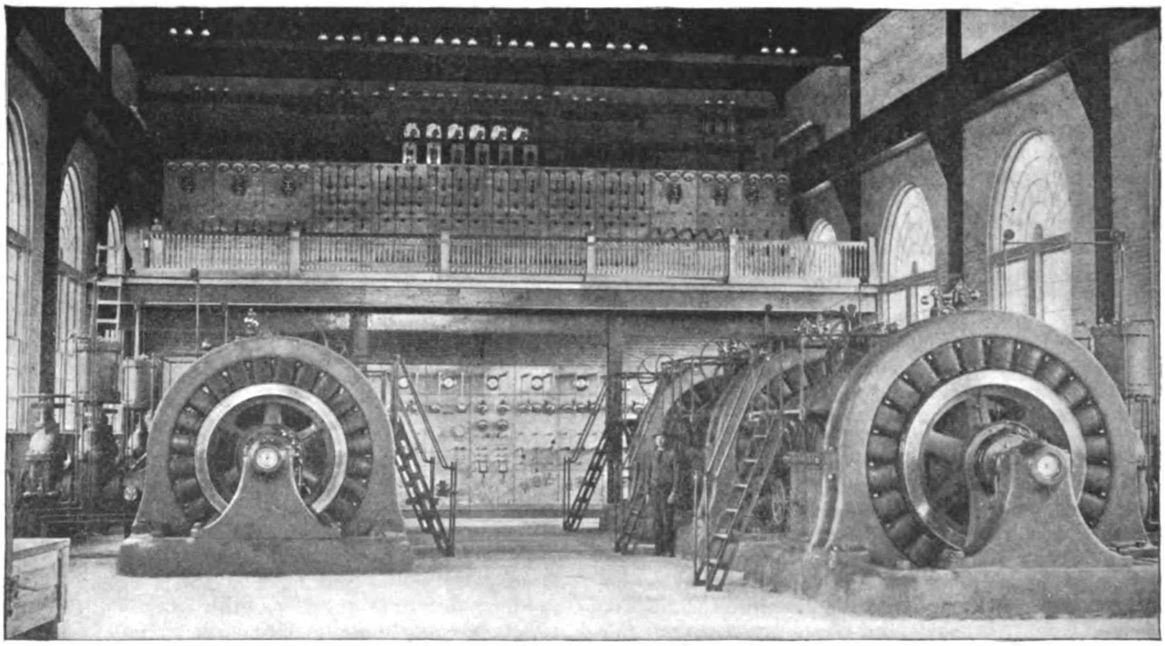
By the recent accomplishment of a scheme of consolidation all the electrical plants in Salt Lake City, as well as the transmission plants, supplying current from it to the outside, have been merged into the Union Light and Power Company. The companies thus consolidated were the Pioneer Electric Power Company, the Salt Lake and Ogden Gas and Electric Company, the

Big Cottonwood Power Company, the Little Cottonwood Power Company, the Citizens' Electric Light Company, and certain smaller interests.

The plant of the Pioneer Electric Power Company is one of the most important installations in the West, and the transmission one of the longest. The power house, shown in the illustration, is located a short distance from the mouth of the Ogden Canon. The power is derived from the Ogden River, the water being brought to the power house through a wooden stave pipe and riveted steel pipe line about 32,000 feet long. The electric plant consists of five General Electric three-phase alternators—24 pole machines running at 300 revolutions, and delivering 750 kilowatts each at 2,300 volts and 60 cycles. The complete plant is designed for 10 units, or a total output of 10,000 horse-power. The exciters are General Electric six-pole 500 volt kilowatt dynamos, each of ample capacity to excite ten generators. Each alternator is directly connected to a Knight water wheel of 1,200 horse power capacity, and each exciter to one of 135 horse power capacity.

The current is fed into the transmission lines from the step up transformers at 16,000 volts, and delivered to the step down transformers at 13,800 volts. They are ordinarily connected in delta, but can also be connected in Y to raise the potential to 25,000 volts whenever it is desired to run at the higher potential in order to increase the capacity of the line or the distance over which the power is to be carried. The switchboard panels on the gallery at the end of the power house are for the outgoing feeders and are arranged to handle potentials of 25,000 and 30,000 volts. Everything necessary to control the operation of the electric and hydraulic machinery has been carried to the switchboard panels on the same level as the generators.

Both step up and step down transformers are of the air cooled type and are each of 250 kilowatt capacity. The pressure of the current for local distribution to the smaller transformers at Salt Lake City is 23,000 volts.



LATEST VIEW OF GENERATING STATION OF PIONEER ELECTRIC POWER, CO., SALT LAKE CITY, UTAH.

PROF. CHAS. A. CARUS-WILSON, of McGill University, Montreal, is leaving for England April 19 to deliver the Cantor Lectures during May in London on "Electric Locomotives." Longmans, Green & Co. are about to publish his book on "Electro-Dynamics, The Direct Current Motor." The treatment will be original, and special attention will be given to the subject of acceleration, and the design of motors for rapid speeding up. A complete solution of the problem is given for the first time.

CROWLEY, LA., is installing an electric light plant. Ball engines, built by the Ball Engine Co., Erie, Pa., furnish the power.

Preparations at the Electrical Exhibition.

Madison Square Garden passed into the hands of the Electrical Exhibition management at midnight on Saturday, and an army of workmen at once began, under the direction of Mr. Marcus Nathan and the officials of the Garden, to get the vast arena in order. The work now in full progress is of an extremely interesting nature, and is itself a fine piece of engineering, including steam and water piping, floor laying, platform building, the erection of booths and stalls, and the preparation by the management and exhibitors of a number of special features. Hundreds of busy people are at work not only in every part of the main floor, but in the huge basement, which contains the operative exhibit, and in the Concert Halls and its annexes, where a number of special features are being placed, including the Historical Wax Tableaux, the Edison Magnetic Ore Separation model, the Third Rail (Hartford and New Britain) model, the Parsell Galvanoplastic exhibit, etc.

Mr. Max Osterberg, the electrical engineer of the Exhibition, has moved his office up to the Garden, and is deep in plans and specifications, getting a wonderful amount of work done in a very short time, with the aid of his partner, Mr. Sutton, and a corps of assistants.

The C & C Exhibit at Madison Square Garden.

One of the most interesting exhibits in the May Electrical Exhibition at Madison Square Garden will be that made by the C & C Electric Company, of New York. In the basement of the building, where the operative exhibits will be placed, there will be shown a C & C multipolar generator directly connected to a 25 h. p. Diesel "Rational Heat Motor," the new type of engine which has created such a stir recently in the engineering field of both Europe and America. (See The Electrical Engineer, February 17.) This exhibit promises to attract a great deal of attention, and the C & C Company's new type of multipolar generator will no doubt come in for a great share of favorable criticism.

On the main floor of the building, the C & C Company will have an exhibit occupying 500 square feet of floor space in which

will be shown all their latest types of machines, including their well known types of bi-polar dynamos and motors in several sizes; also quite a full line of their now celebrated closed type ironclad motors and dyanoms. These machines of the ironclad type will be shown, some separately and some in combination with other machinery. The 20 h. p. enclosed ironclad motor will be shown mounted in connection with a Lambert hoist and one of the dynamos directly connected to a Case engine.

The exhibit will also include one of the ironclads fitted up with back gears for speed reduction. Two of the company's slow speed belt type generators will be exhibited and these excellent machines will undoubtedly be greatly admired as they are particularly attractive in design and the workmanship embodied in their construction as well as the materials employed are of the very highest order. Numerous other interesting machines, appliances and parts will be also shown.

A C & C switchboard will form an attractive feature of each exhibit.

The Telephone at the Exhibition.

The New York Telephone Company will make an admirable exhibit illustrative of the operation of the telephone system of this city. There will be shown specimens of the latest styles of telephone apparatus and silence booths for the equipment of public and private telephone stations. Pretty nearly everybody is more or less directly interested in the telephone service nowadays, though few know just how it works. The New York Telephone Company's exhibit will give visitors to the show a very fair idea of just how the service does work as part of the exhibit will be a switchboard in actual operation, which will serve stations at various points in the Exposition building. Trunk lines will run from the Exposition switchboard to one of the main exchanges, so that the stations in the Exposition may not only be connected directly to each other, but also to any station in the city or in any part of the country reached by the telephone systems of the New York, the New York and New Jersey and the American Telephone and Telegraph Companies.

In short, this part of the exhibit will be a working specimen of the Private Branch Exchange System, which has been so largely adopted by big business houses of all classes since its introduction by the New York Telephone Company a year or two ago.

Arrangements are also making for a separate telephone feature which will be the transmission of music from various New York theatres and out of town points every evening during the month of the Exposition. The Exposition Company, the American Telephone and Telegraph Company and the New York Telephone Company are working jointly in the production of this attraction, which is sure to be popular with the general public.

The Gerlach During the Exhibition,

Mr. C. O. Baker, Jr., president of the Electrical Exhibition Company, has engaged a large banquet room and parlors as a general meeting room and headquarters for delegates and visitors, at the Gerlach Hotel, 49 West 27th street, New York city. This will prove a great boon and convenience to all connected with the exhibition.

Historical Wax Tableaux at the Exhibition.

A series of eight illustrative and historical wax tableaux, designed to mark some of the successive stages of electrical development, prepared by Dr. Park Benjamin, Professor F. B. Crocker and Mr. T. C. Martin, executed and arranged by the Eden Musee Company, will be a feature in the Concert Hall.

The series will include the First Recognition of an Electric Effect, when the Syrian woman, centuries before our era, wonderingly perceived light objects flying to her amber spindle; the Mariner's Compass, ascribed to the Chinese and Italians, but probably to be credited to the Finns, in the eleventh century; the Earth a Great Magnet, Dr. William Gilbert, explaining the Terella to Queen Elizabeth, 1600; the First Conductors or Circuits, Stephen Gray, a Charter-house pensioner in London (1720), experimenting on the conduction of electricity; The Leyden Jar, showing the bottling of electricity and the terrible shock to Dean Von Qliest, Canon of the Cathedral in Cumin, in Pomerania, 1746; The Identity of Lighting and Electricity—when Benjamin Franklin drew down the lightning from the skies, 1752; The Beginnings of the Modern Primary Battery or Voltaic Cell, with Galvani's famous frog experiment, 1791, and the Beginnings of Modern Dynamo-Electric Machinery, showing Michael Faraday's famous experiment, 1831.

These tableaux are accompanied by a selection from Dr. Park Benjamin's celebrated library of early philosophical, technical and electrical books, each illustrating some feature or stage of electrical evolution.

Exhibit of the Hebrew Technical Institute.

For some time past the Hebrew Technical Institute has made a great success of its instruction in the technical branches of celetricity, as distinguished from the mere teaching in a manual of trade school. Evidences of the ability of the students under Mr. Ker will be given at the Exhibition, where opportunity is being afforded for an excellent display of the electrical engineering skill of the boys. Not only will a number of instruments be entered for the model-making competition, but these will be supplemented by other instruments and apparatus built by them, to illustrate principles and phenomena. There will also be a complete small plant in operation lighting a small house. A collection of blue prints and photographs will also be included.

Sprague Elevators at the Electrical Exhibition.

Considerable interest is attached to the exhibit of the electric elevator machine for the London Underground Railway, which is to be shown at the Electrical Exposition to be held in Madison Square Garden commencing May 2. The London machines of this type are the largest elevator machines ever built, and were built by the Sprague Electric Company.

Mr. Charles Chamberlain.

Mr. Charles Chamberlain has been placed in charge of the Press Bureau of the Electrical Exhibition. He is well known as a successful press agent, and being familiar with machinery, etc., will be able to the many engineering features of the show.

The Exhibit of The Edison Electric Illuminating Co. of New York.

The exhibit of the Edison Electric Illuminating Co. of New York occupies, in three sections, the first of the larger spaces, containing about 800 square feet, at the right of the main entrance. In it are shown the more important applications of electricity to industrial and household purposes. The central section, surmounted by a dome, is devoted to electric lighting. For incandescent lighting there are miniature and candelabra lamps, ranging from 1 to 8 candle power; standard lamps, from 8 to 100 candle power; reflected ceiling lighting, the lamps being concealed from view, the new reflector lamps, sign lighting, advertising designs, etc. In arc lighting are shown standard and Bijou enclosed lamps, ranging from 400 to 2,000 candle power, and burning continuously with one trimming of carbons from 100 to 150 hours; projectors, for photographic and stage purposes, replacing the calcium light, and the larger focusing searchlights, of sufficient power, if desired, to throw a beam of light fully a hundred miles. Under-supported lamps, feeding from below, very suitable for post and doorway lighting, are also shown. The end section, nearest the entrance, is devoted entirely to electric cooking and heating, the devices being in practical operation. In addition to smoothing irons, tea kettles, chafing dishes, hair curlers, portable stoves, etc., there is shown the new and very ingenious electric heater for repairing bicycle tires. The third section is devoted to power, largely "direct-connected," avoiding intermediate shafting and belting. There are to be seen a printing press and book binding machinery, direct acting pumps, apparatus for ventilation, lathes, drills, et.c A new refrigerating plant, operated by a motor, showing the actual freezing of water, and an electric forge, for welding and other purposes, in which pieces of metal can be instantly brought to a red heat, are for the first time publicly exhibited in this city. The electric fan blowing hot instead of cold air, is also a new device. The arc lamps on the promenade, over the arena boxes, are supplied by the Edison Company, and show its system of street lighting. The Edison Company supplies current for the entire lighting of the building, as well as for the street lamps and its own exhibit. It is also supplying,

directly from its service in the building, the current used in the vacuum tube lighting of the chapel in the Assembly Rooms. That company continues to have the largest connected installation in the world, supplying from its six stations more than 7,500 customers, nearly 370,000 incandescent and more than 5,000 arc lamps and 20,600 horse power in motors, in all an equivalent of 736,000 lamps of 16 candles.

Fine Exhibit of The Walker Co., of Cleveland.

The Walker Company, of Cleveland, are making one of the finest exhibits at the Garden. Mr. J. S. Anthony, of the home office, will be in charge, and is now in the city preparing all the work. The Walker Company will exhibit at Madison Square Garden two of their No. 20 L motors, mounted on truck; one No. 20 L motor, dismantled to show construction; two No. 4A street car motors, mounted; one 50 kilowatt belted alternator; 1 50 kilowatt street lighting generator, direct connected to Armington & Sims engines, Type "S" controllers, assembled and dismantled; railway switchboard complete with feeder and generator panels; ornamental arc lamps; new Walker recording wattmeter, and a large display of photographs of its apparatus. Besides this, there will be a complete section of the new underground conduit with a Broadway car shown in operation.

Demonstrating the Use of Submarine Mines.

Mayor H. J. Smith, of Pompton, N. J., one of the best known experts in the world in submarine explosives, mines, etc., has very kindly tendered his services to the Exhibition management for the demonstration in a special tank of the manner in which harbors are protected, ships blown up, etc., and some of his ingenious apparatus has been loaned for this interesting work by Mr. C. McLaughlin, of J. H. Bunnell & Co. This will probably be one of the most attractive features of the show.

NEWS AND NOTES

Guarding the Long Island Coast.

A party of linemen of the Western Union Telegraph Company are at work putting in wires at the life-saving stations on the Long Island coast to establish direct telegraphic communication with the forts and Governor's Island. A corps of engineers from Willets Point will be stationed at Quogue, while the signal corps of the Naval Reserve will make their headquarters in Southampton. Islip is also to be made a government telegraph station. It is understood that the War Department will in addition establish direct telegraphic communication between the most distant points of Long Island bordering on the Sound and Fort Schuyler, Fort Slocum and Willets Point.

Electrical War News.

The United States Government has cut the Key West cable to Havana and taken control of the cable for all purposes, establishing a strict censorship over messages of every kind. The staff of the Western Union Telegraph Company has been excluded from the office and Captain Thompson, United States Army, has taken charge.

The following letter has been addressed by Willard E. Case, vice-president of the New York Electrical Society, to Professor F. B. Crocker, Columbia University.

"In view of the fact that the efficiency of electrical fighting equipments on land and sea will form a vital factor in the present war, I would submit to you, as the representative of the Electrical Department of Columbia University, and as a member of the council of the American Institute of Electrical Engineers, the following suggestion: That the professional and skilled electricians of our universities, colleges and electrical societies shall form themselves into a body which shall supplement the electrical corps engaged in active work on the water and in the field, to be available to the Government for expert advice in all matters relating to the utilization of electricity in naval and military operations, thus adding to the present regular expert electrical resources of the Government."

The Board of Directors of the New York Edison Electric Illuminating Company authorize the following announcement:

"All employés of the Company now enrolled in the militia or naval reserve organizations of the State, who may volunteer or be called to active service, will have their positions held open until their return, and during absence for such service their salaries will be continued, provided the absence does not extend beyond one year. Those acting under the foregoing should notify in writing their respective Heads of Departments to whom their salaries should be paid during their absence."

The following notice has been posted in the General Electric Works:

"If employés of the company are called by the Government for service it will be the intention and desire of the company to re-employ them at the expiration of their term of Government service if they shall not then be incapacitated for duty."

The company employs about 5,000 people.

MR. W. F. OSBORNE, so long representing the Western Electrician in the East, will become on May 1 business manager of the "National Provisioner," published weekly in this city.

MR. MARTIN INSULL, member of the firm of Sargent & Lundy, of Chicago, the energetic Western agents of the C & C Electric Co., has been in New York City for a week, in conference with President Dwight. He brought some good orders with him and found the factory already running double shift filling contracts for all classes of its well known apparatus.

SOCIETY & CLUB NOTES

New York Electrical Society.

In consequence of the illness of Prof. Sidney H. Short, and the fact that so many of the members of the society are engaged in active work on the Electrical Exhibition, it has been decided to give Professor Short's lecture on "The Outlook of Heavy Electric Traction," during the exhibition.

At the Electrical Exhibition there will be various demonstrations of scientific phenomena and principles by means of models and apparatus, which will be in more or less continuous operation. As the society has been entrusted with a great deal of the work of this kind it would like to secure from among its members the help of volunteers to take charge of various features from time to time; the duty will not be heavy, but will be made as light as possible.

The first applications will be selected, preference being given, as far as possible, in case there be a large number of applicants, to students of educational institutions. The assignment to duty will be in the hands of a committee of the society and the Exhibition Company, and the work of such members will be publicly recognized.

American Institute of Electrical Engineers.

The 124th meeting of the Institute will be held at 12 West Thirty-first street, New York city, on Wednesday, April 27, 1898, at 8 o'clock P. M. A paper will be presented by Professor W. E. Goldsborough, of Lafayette, Ind., entitled "An Economy Test of a Central Station"; also a paper by Charles J. Reed, of Philadelphia, Pa., on "A Novel Form of Thermo-Electric Battery." This paper will be accompanied by experiments with the apparatus described.

Henry Electrical Society.

The 102d meeting of the Henry Electrical Society will be held on Friday evening, April 29, 1898, at Columbia University, 116th street and Amsterdam avenue, in the Engineering Building, Room 302. On this evening Prof. F. B. Crocker will address the members of the society on "The Design of Circuits for Electrical Distribution," the questions of regulation being illustrated by numerous experiments.

ATLANTA, GA.—The shops of the Southern Bell Telephone Company have been pressed into service for building special submarine mine apparatus for het Navy Department.

THE STOCK MARKET

War and Recovery in Prices.

As might have been expected, the moment there was some certainty about things, the stock market pulled itself together, and prices have been better; the net decline for the week has been very small. Want of activity has been the chief characteristic. During the week, the sales of Western Union were 7,154 shares, closing at 85½; of General Electric the sales were 4,880 shares, closing at 31¼. Only a few hundred shares of American Bell Telephone were sold in Boston, at the unchanged price of 247.

Copper is showing a still upward tendency, and is now quoted at 12@12½ cents. Heavy steel rail, Eastern mill is $18 per ton. Owing to Government orders on top of a large trade demand, many lines of electrical apparatus have been much sought after.

MARRIED

Blackwell-Searles.

New York Avenue Methodist Episcopal Church, Brooklyn, was the scene of a brilliant bridal last week. Miss Grace Anita Searles, daughter of John E. Searles, secretary and treasurer of the American Sugar Refining Company, was married to Mr. Francis Ogden Blackwell, of the General Electric Company, Schenectady. Bishop Hurst, of Washington, D. C., officiated at the ceremony, which took place at 8:30 o'clock in the evening. The bride was beautifully gowned in white satin enveloped in a tulle veil. She carried lilies of the valley. Two nieces of the bride, Miss Anita Stearns and Miss Helen Stearns, attended her. They were gowned in white point d'esprit and carried baskets of pinks. The bridegroom was supported by his brother, Mr. Josiah Low Blackwell, of Baltimore, as best man, and his ushers were Mr. Maurice Oudin, Mr. W. L. R. Emmet, Mr. E. A. Carolan, Mr. Stewart Brown, Mr. Frank Enos, Mr. John Conover, Mr. J. Parker Dodd and Mr. Louis Stearns.

A large reception was held at the Searles residence on St. Mark's avenue. Lilies and spring blossoms formed the decorations, which were artistically displayed through the spacious rooms. Mr. and Mrs. Blackwell will live in Schenectady. Mr. Blackwell, though still a young man, has had a long, active and honorable career as an electrical engineer and inventor, and has the hearty congratulations and good wishes of a host of friends.

PERSONAL

Presentation to W. F. Bossert.

W. F. Bossert, of the Bossert Electrical Company, Utica, N. Y., celebrated his fiftieth birthday on April 17. When the men ceased work in the afternoon they presented to Mr. Bossert an upholstered smoking chair of quartered oak, the presentation speech being made by C. H. Scofield. Saturday evening in Music Hall Mr. Bossert gave his employés, members of the company and members of the Maennerchor, a banquet and at its close Professor Zarth presented to the host a handsome Maennerchor badge suitably inscribed.

Mr. George H. Finn.

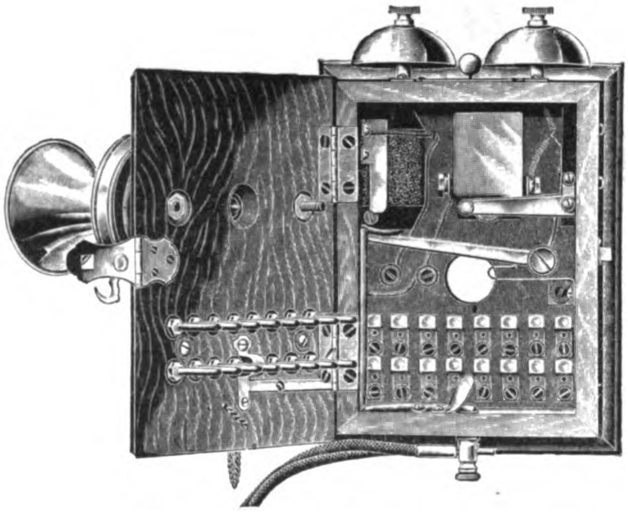
Mr. George H. Finn, formerly secretary, treasurer and general manager of the Edison Electric Light & Power Co., of St. Paul, Minn., has left for Boston, where he has been appointed as general manager of the New England Gas & Coke Co. Mr. Finn has been connected with the Edison Co. at St. Paul since it was started in 1886. Since the consolidation of the electric lightning industries in that city he has also been intrusted with the management of the St. Paul Gas Light Co.'s electric plants.

Mr. Finn was the first to start in St. Paul the system of underground conduits. His management of the company's affairs has been very flattering, and his twelve years' residence had placed him in the front rank of the business men of St. Paul.

TRADE NOTES & NOVELTIES

Schmidt and Bruckner's Improved Telephone Apparatus.

THERE is perhaps no commercial piece of apparatus which can compare in delicacy of adjustment and construction with the electric telephône, and none, considering this fact, which has to stand rougher and more unskilful usage. This unfortunate combination, as will appear evident, makes it necessary that the utmost care be taken in the construction of each detail of the instruments, rendering each portion durable and at the same time sufficiently delicate to have it perform satisfactorily its function in the accurate transmission of the human voice. These facts and the dissatisfaction of the public with



SCHMIDT & BRUCKNER INTERCOMMUNICATING TELEPHONE, OPEN.

cheap telephones which continually get out of order and need repairing, have been carefully considered by Messrs. Schmidt and Bruckner, 209 Greenwich street, New York, in the design of their complete line of telephone appliances.

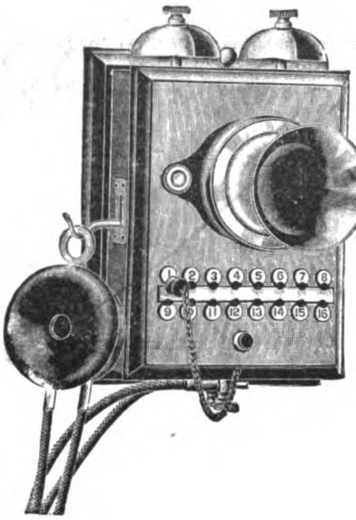
Their transmitter, which is of the coal grain type, is said to be an improvement on the well known Ericsson Swedish transmitter. A thin disc of shellacked silk is used to protect the carbon grain from moisture, and a solid gold disc with projections to increase its surface is used at the back of the diaphragm. These improvements add materially to the efficiency of the instrument and make it much more satisfactory in its operation.

The company's receiver is a very sensitive instrument, is of the double-pole, laminated magnet type and is constructed with the utmost care. The magneto possesses a number of admirable features, among which may be mentioned the long flexible contacts, the centrifugal shunting device, and platinum contacts throughout.

The two illustrations represent the company's very compact wall intercommunicating telephone set. One of the admirable features of the firm's apparatus is the absence of wires and cords inside the box, all interior connections being effected by means of contact between pins and flat springs. The pins, fastened on the door of the box, impinge upon flat spring terminals when the door is closed, bringing the discs on the outside of the box in direct and positive contact with their respective lines. A

double bell arrangement is used which gives a certain and agreeable signal, no magneto, however, being employed. To call any station, it is only necessary to insert a brass plug at the proper disc and push a button. The exterior appearance of these sets is highly commendable and the workmanship is of the very best quality. Compactness is one of the most noticeable features of the company's apparatus, which have met with the entire satisfaction of its users.

Among the latter using the magneto system may be mentioned John Wanamaker, Kerbs, Wertheim & Schiffer, Buckingham Hotel, Uptergrove Bros., Russell, Burdsall & Ward, Long



SCHMIDT & BRUCKNER INTERCOMMUNICATING TELEPHONE, CLOSED.

Island State Hospital, Rathbone & Son, Smith & McNell, Central R. R. of New Jersey, Irving Place Theatre, Weber & Bunke, Trenkman & Co. and Berger & Worth. The following use the company's battery system: Ernest Flagg, Fleming & Kohler, International Exploration Co., Singer Sewing Machine Co., Chilton Paint Co., McKesson & Robbins, Lloyd Plate Glass Co.; N. Y. Quinine Co., A. S. Banter, R. & G. Corset Co., Velvetine Bias Co., Steinhardt Bros., De Fries & Co., Dusseldorf, Germany, and F. Heidrich, of Merida, Mexico.

The Knapp Motor and Gordon-Burnham Battery Combination.

WHAT will certainly prove to be a very effective business combination has recently been entered into by the Knapp Electric Novelty Co., 47 Warren street, New York, and the Gordon-Burnham Battery Co., 82 to 86 West Broadway, New York. The combined outfit (Fig. 3) which these companies will place upon the market will consist of the well known Knapp electric motors, which have been entirely remodeled, are efficient, powerful and thoroughly made, and the Gordon cell, for which long life and efficiency, economy, freedom from local action, gases and odors and low internal resistance are claimed. The Knapp battery motor, shown in Fig. 1, has a three-pole armature, is mounted on a neat mahogany base, and is fitted with a pulley and starting switch. The merits of the Gordon battery are so well known that no further mention of them need be made here. It is equally well adapted for open and closed circuit work, and when used for the latter gives from one to six amperes per hour, with an available e. m. f. of 65 to 75 hundredths of a volt. Besides manufacturing the types of B, C and D motors, the Knapp Electric Novelty Co. manufacture the well known Little Hustler Motor, shown in Fig. 2. The armature having three poles enables the motor to be started without assistance, when the current is applied. It drives a five-inch fan at a high rate of speed, and is fitted with a pulley for running toys, etc. The complete outfit referred to above will be shipped directly from the factory of the Gordon-Burnham Battery Co. This agreement between the two companies in no way interferes with the sale of the Knapp motors without batteries, which they will continue to handle with the same vigor as formerly. We may note that on May 1 the Gordon-Burnham Battery Co. will remove to 594 Broadway, seventh floor, where they will have an enlarged floor space, necessitated by the ever increasing business of this firm.

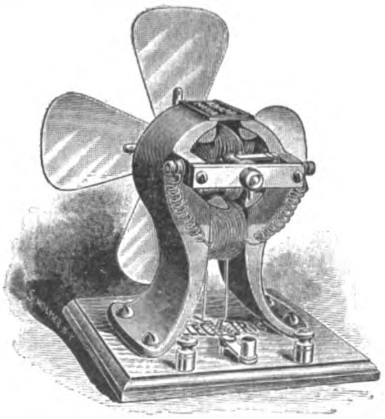


FIG. 1.- REAR VIEW OF C AND D TYPES, KNAPP MOTOR.

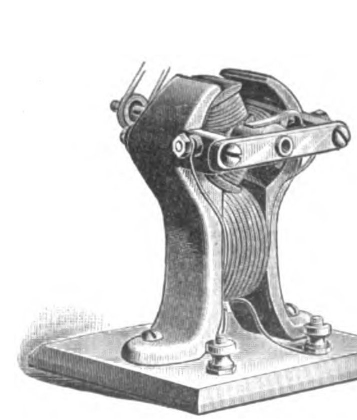

FIG. 2.—"LITTLE HUSTLER" KNAPP MOTOR.

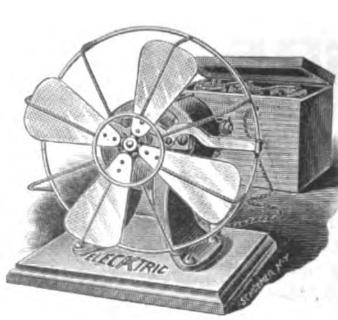

FIG. 3.—KNAPP MOTOR OUTFIT COMPLETE.

Activity of the Sprague Electric Co.

The John Stephenson Company, Limited, have just awarded the Sprague Electric Company another large contract for Lundell power motors with which to equip their blacksmith and machine shops. The John Stephenson Company, as is well known, are erecting a new car building plant at Elizabethport, N. J., and for this plant the Sprague Electric Company have secured contracts for Lundell motors for the mill shops, cabinet shop and blacksmith and machine shops.

The Sprague Electric Company have just received an additional contract for the equipment of the Library of Congress in Washington, with Lundell exhaust fan outfits. All of the outfits will be operated by Lundell power motors.

Lynn Incandescent Lamp Co.

A summary of the winter's business of the Lynn Incandescent Lamp Company, of Lynn, Mass., shows that nine out of ten of their shipments are to old customers and that five out of eight are to lighting stations. This demonstrates that station managers are appreciating their efforts to furnish them with a good lamp at reduced cost, and that they are making it possible and profitable for the station manager to use a lamp of a higher efficiency and to replace them oftener.

It has been a much disputed point as to whether it is cheaper to put money into the renewal of lamps or to use a lamp consuming more power and of longer life than to put money into coal. The nice, bright, clear light of a higher efficiency lamp is certainly the most satisfactory to the customer. The renewal of incandescent lamps certainly appears destined to play an important part in the economy of station practice in the future. The Lynn Lamp Co., however, we believe are entitled to be considered the pioneers and the largest company. At least our readers have seen their advertisements in our columns for the past two years.

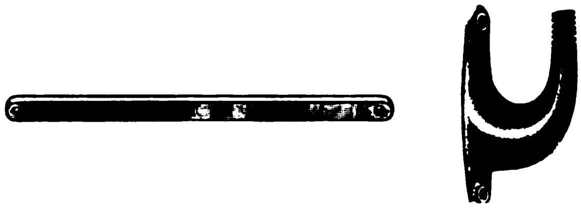
Central Electric Co.

The Central Electric Company, of Chicago, is now furnishing the celebrated Manson tape put up in neat tin boxes, holding one-half pound each. This innovation will be readily appreciated by the many users of this product, as it preserves the tape in a fresh condition and also prevents filings and the many particles of metal always found in a "kit" or on a bench from adhering to the tape and destroying its effectiveness.

The Central Electric Company is carrying in stock a full and complete line of the celebrated McIntire connectors, as well as the various tools used in connection therewith.

Cross Arm Braces and Feeder Brackets of the Coulter and McKenzie Machine Co.

The Coulter and McKenzie Machine Co., of Bridgeport, Conn., manufacturers of electric light and telephone specialties are calling special attention to their improved cross arm braces and feeder brackets illustrated below. The cross arm braces are made up in large quantities of the usual sizes, either plain or galvanized, and are shipped to all parts of the country to large electric light and telephone companies and used to support the cross arms on the poles. It is customary to set one on each side of the pole at an angle of 45 deg., and generally one bolt through the pole connects the two at the lower end. The feeder brackets shown are used for trolley work and generally shipped in black asphalt finish. These goods are kept in stock and can be furnished at once at very low rates.



COULTER AND McKENZIE CROSS-ARM BRACE AND BRACKET.

Sales of Erie Ball Engines.

The Great Northern Hotel, Chicago, will in the near future install a very complete electric plant, consisting of three 225 h. p. Ball cross compound engines, built by the Ball Engine Company, Erie, Pa., each direct connected to 150 k. w. Western Electric generator. The Ball Engine Company are building an engine to go to Mexico. The Rowe Building, East End, Pittsburg, will have an electric plant, Ball engines, built by the Ball Engine Company, supplying the necessary power.

WESTERN NOTES

AM. ELEC. FUSE CO. are now located at 521-531 Wabash avenue, Chicago. Their new works are so equipped that they can manufacture goods with far more speed owing to the improved machinery they have just completed. They are now in a position to turn out any size, shape or form of fuse wire and links for telephone, telegraph, electric light and electric power circuits.

BRYAN & HUMPHREY, Turner Building, St. Louis, have issued an extremely neat pamphlet in reference to the range of their work as consulting mechanical and electrical engineers.

BOARD OF PUBLIC WORKS of Grand Rapids, Mich., who have been advertising for bids for an electric lighting plant have postponed the opening of bids to Thursday, May 5, at 2 o'clock p. m.

THE ELECTRIC APPLIANCE CO. have increased their line of enclosed Upton arc lamps by the introduction of a new enclosed lamp for alternating work. This lamp is giving very satisfactory results and gives every promise of being equal in every respect to the direct current enclosed lamps. The Electric Appliance Company have one of these lamps burning in their store and it has been commented on favorably by all who have watched its operations.

MR. JAMES F. CUMMINGS, the energetic president of the Armorite Company, has, we regret to learn, been ill in Detroit for the past month, but has now entirely recovered, and will in a short time start out on a business tour. He is expected first in the East.

THE WESTERN ELECTRIC COMPANY announces that it has the exclusive Chicago agency for the Sprague Electric Company's conduit and has in stock in Chicago a large and complete supply of interior conduit of all sizes upon which it is prepared to quote the lowest prices.

CENTRAL ELECTRIC COMPANY report that there is an encouraging use of the various electrically heated utensils for cooking and other purposes. The adaptability of this type of apparatus to diversified uses seems to have struck the popular favor. They are carrying all of the various heating and cooking appliances and can make shipments from stock.

GARTON-DANIELS ELEC. CO., Keokuk, Ia., report that business in their Garton lightning arresters is very good. Mr. J. V. E. Titus, the secretary, says: "Business is still holding up to a gratifying extent. Inquiries are coming in in a deluge, showing that wise managers are preparing 'coast defenses' for the impending war of the elements."

NEW YORK NOTES.

THE MANHATTAN ELECTRICAL SUPPLY CO., 32 Cortlandt street, New York City, state that their business has grown to such proportions that the list of people employed by them now exceeds more than 250 men. It is interesting and encouraging to note that this well known concern started ten years ago this month, with one employé, and a capital of less than $100. Moreover, no outside capital was ever invested in the enterprise, its increase arising entirely from the profits accumulating within the business itself and used to push out into new lines and larger fields. Such a record as this must arrest attention. It speaks volumes for the high capacity of the management and for the opportunities that abound in electricity for those who are alert enough to see them and shrewd enough to seize them.

NEW YORK CITY. The New York Edison Electric Illuminating Company reports for March an increase of $56,105 gross and $18,804 net. The gain for three months is at just about the same rate.

McINTOSH, SEYMOUR & COMPANY, of Auburn, N. Y., have moved their New York office in the Havemeyer Building to rooms 1,010 and 1,011, where Mr. Merrill will be glad to attend to all inquiries for their well known steam engines.

CHANGE OF ADDRESS.—A post office has been established at Ampere, New Jersey, and all matter for the Crocker-Wheeler Company there should be addressed accordingly.

THE NORDEN ELECTRIC COMPANY, Broadway and 25th street, Mortimer Norden, manager, report that they have contracted to install over 2,500 lights at the Electrical Exhibition for the following firms: Sprague Electric Co., Electric Storage Battery Co., C. & C. Electric Co., Crocker-Wheeler Electric Co., John A. Roebling's Sons Co., Nash Gas Engine Co., Diesel Motor Co., Thos. A. Edison, Jr., Cutter Electrical and Manufacturing Co., American Circular Loom Co., Paragon Motor Co., Chas. S. Wirt, Hope Electric Appliance Co., The Electrical Engineer, and others.

GENERAL ELECTRIC COMPANY has had to fill a rush order for the Navy Department of 25,000 incandescent lamps, going direct to Key West for the fleet there.

PHILADELPHIA NOTES

QUEEN & CO., INC., of Philadelphia, present in a new circular a description of their Queen Acme portable testing set. Their claims for this instrument as to range and accuracy of measurement are very emphatic. The testimonials in the new circular suggest that the set is widely used, both in this country and abroad. This descriptive pamphlet will be sent on application to those interested.

WASHINGTON CARBON CO. have brought out a patriotic blotter containing a picture of the immortal George together

with a copy of the American flag and a paragraph from the Star Spangled Banner.

MECHANICSBURG, PA., invites sealed proposals until May 10 for 47 or more arc lights of 1,600 candle power, and 12 or more incandescents of 32 candle power, the arcs to burn every and all night, and the incandescents to burn every night until 12. The term of contract is one year. C. N. Owen is chairman of the light committee.

ADVERTISERS' HINTS

THE KEYSTONE ELECTRIC CO., Erie, Pa., remind the public that they are building direct-connected and belted generators for light and power and slow speed enclosed steel motors for the various kinds of service to which this type of motor has been found applicable.

THE C. & C. ELECTRIC CO., 143 Liberty street, New York, advise those who wish to see an exhibition of strictly up-to-date, high grade apparatus to visit their headquarters at the Electrical Show at Madison Square Garden.

JNO. A. ROEBLING'S SONS CO., Trenton, N. J., state that economy in the construction and maintenance of overhead wires can best be obtained by the use of bi-metallic wire, because it possesses sufficient conductivity for all purposes, which insures good service, and it has great strength, which reduces the cost of maintenance.

THE MONTAUK MULTIPHASE CABLE CO., 100 Broadway, New York, are now able to supply interior thermostatic electric cables in all standardized B. & S. gauges. It will be remembered that these cables were recently adopted by the Gamewell Auxiliary Fire Alarm Co.

WILLIAMS & ABBOTT, 154-156 Champlain street, Cleveland, Ohio, claim to be the manufacturers of the best magnets made. They will make special prices on large lots of receivers and binding posts.

THE NORDEN ELECTRIC CO., 145 West 28th street, New York, have installed at the Madison Square Garden the exhibits for a large number of well known electrical concerns of which they publish a list in their "ad."

J. B. COLT & CO., 115 Nassau street, New York, have prepared stereopticon slides which are now ready, illustrative of the Spanish-Cuban question.

THE COLUMBIA INCANDESCENT LAMP CO., St. Louis, Mo., state that their claim of superiority of their lamps would never be maue if there was not foundation for it.

THE FULLER COMPANY, Detroit, Mich., are equipping the finest steamers on the lakes with electric and ventilating outfits.

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, say their electrical specialties are factors of success in every first class electrical installation.

GORDON BURNHAM BATTERY CO., 594 Broadway, New York, advertise a battery fan outfit to run 150 hours before renewing battery. The fans are in 6, 8 and 10-inch sizes.

FRANKLIN H. KALBFLEISCH CO., 54 Maiden Lane, New York, make a specialty of battery solutions for telephones and acids for storage batteries.

PALMER ELECTRICAL INSTRUMENT CO., 26 North Seventh street, Philadelphia, advertise electrical apparatus for students, schools and colleges.

THE CENTRAL ELECTRIC CO., 173 Adams street, Chicago, will move the first of May to 264-270 Fifth avenue.

F. A. LA ROCHE & CO., Thirteenth and Hudson streets, New York, advertise the "Ideal" circuit breaker.

THE GRASSELI CHEMICAL CO., Cleveland, Ohio, manufacture the "Snowflake" soldering salt for electrical and other purposes. They also supply sulphuric acid of 1.200 specific gravity for storage batteries.

THE BILLINGS & SPENCER CO., Hartford, Conn., continue to find a ready market for their drop forged fine lake copper commutator bars.

THE HIGH TENSION STORAGE CO., Heed Building, Philadelphia, have a word to say about the methods of charging their batteries.

THE DEARBORN DRUG & CHEMICAL WORKS, Chicago, state that there is no water produced by nature perfectly fit for use in boilers without treating. Their specialty is to analyze a sample of water and then prescribe a solution to suit each case.

THE AMERICAN HARD RUBBER CO., 9-13 Mercer street, New York, announce their succession to the businesses of the India Rubber Comb Co., The Butler Hard Rubber Co., and the Goodrich Hard Rubber Co. They solicit the favors extended to their predecessors.

HART & HEGEMAN MFG. CO., Hartford, Conn., say that in their catalogue "C" all that is latest and best in switches, standard and flush, may be found.

ZAHM & WILLIUS, of St. Paul, Minn., have been appointed consulting and supervising electrical engineers for the municipal puant about to be installed at Superior, Wis. The plant will consist of 200 2,000 c. p. and 300 1,200 c. p. arcs for street lighting, and two 1,000 light two-phase alternators for commercial lighting. Specifications are now being prepared and bids will be asked for immediately.

CRAGE & TENCH, of Buffalo, have secured the contract for building the Lima & Honeoye Falls Electric Railroad. The contract also includes the wiring of the streets of both villages for elecrtic lights, and the construction of the power house. A large force of men will be put to work on the job, next week.

The Electrical Engineer.

Vol. XXV. MAY 5, 1898. No. 522.

ELECTRIC TRANSPORTATION

New Electrical Equipment of the South Side Elevated Railroad, Chicago.

BY J. R. CRAVATH.

THE eyes of the entire electric railway world have been turned for several months past toward the South Side Elevated Railroad of Chicago, which has been changing its motive power from steam to electricity. In making this change two interesting engineering novelties are being made use of, viz.: the Sprague multiple unit system of motor car control and a cooling tower for condensing water for a station of 7,200 horse power capacity, located on valuable city land, where room is limited. These two features alone are enough to arouse un-

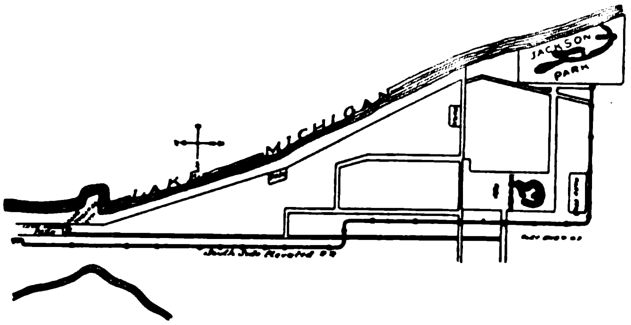

FIG. 1.—MAP SHOWING ROUTE OF SOUTH SIDE ELEVATED R. R., CHICAGO.

usual interest in the installation, to say nothing of the many other details, which deserve attention.

The South Side Elevated Railroad, or, as it is commonly known in Chicago, the "Alley L," (so called because of the location of its right of way) was first opened for traffic in 1892, and at that time its line extended from a down town terminus at Congress street straight south between Wabash avenue and State street as far as Thirty-ninth street. It was extended rap-

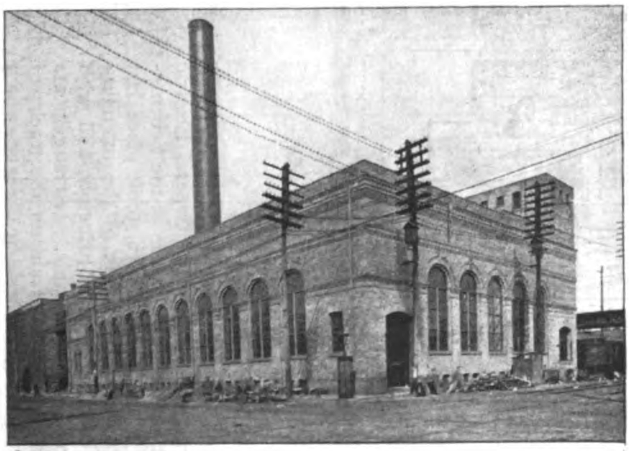

FIG. 2.—POWER HOUSE, SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

idly and when the World's Fair opened in 1893 it reached Jackson Park, running direct into the Fair grounds. After the Exposition followed a long period of poor traffic, the road went into receiver's hands, and finally a complete reorganization took place, by which the property passed from the hands of the old company, known as the Chicago and South Side Rapid Transit Railroad Company to the present South Side Elevated Railroad Company. In the meantime the economy of electrical operation over steam, as shown beyond question by the experiences of the Metropolitan and Lake street elevated roads of Chicago, and by the Intramural at the World's Fair, began to excite a strong desire on the part of the South Side management to reduce

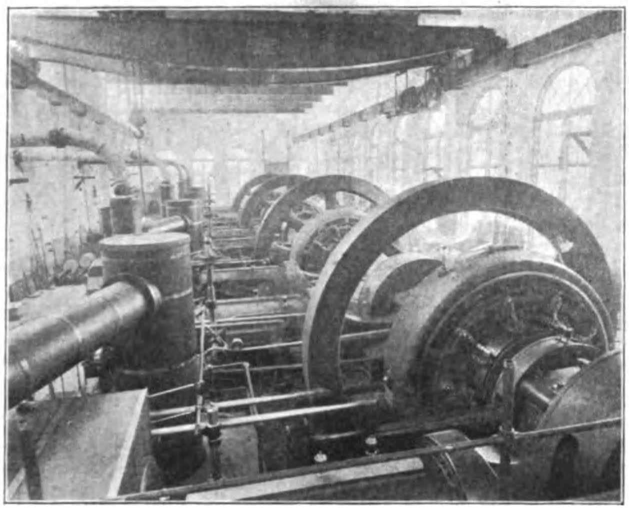

FIG. 5.—ENGINE AND DYNAMO ROOM, SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

operating expenses in a like manner, and it therefore was not strange that soon after the reorganization steps began to be taken toward electrical equipment.

In February, 1897, Sargent & Lundy, of Chicago, were called in as consulting engineers to prepare estimates as to probable cost, and in April of the same year it was definitely decided to go ahead with the electrical installation. Messrs. Sargent & Lundy

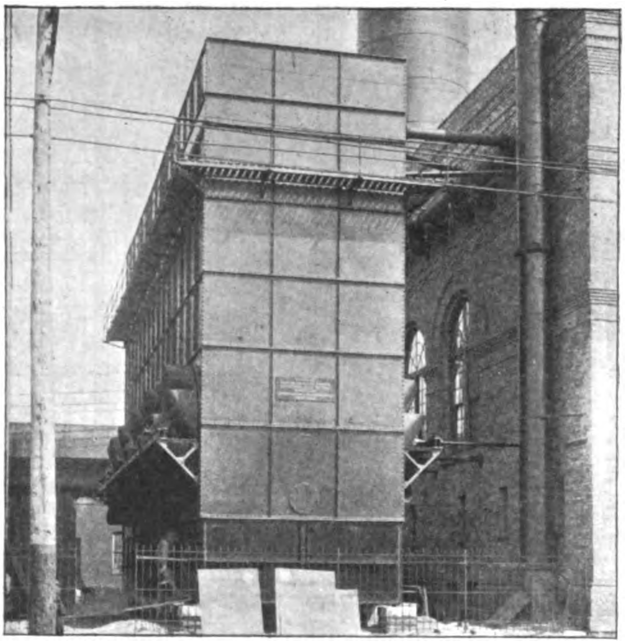

FIG. 6.—COOLING TOWER OF THE SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

were retained as consulting engineers for the entire work. Soon after this Mr. Frank J. Sprague appeared on the scene with plans for the now well known but then scarcely heard of multiple unit system of motor car operation and control. Mr. Sprague's plans were received so favorably that a provisional contract was made with him to adopt the system after the satisfactory equipment

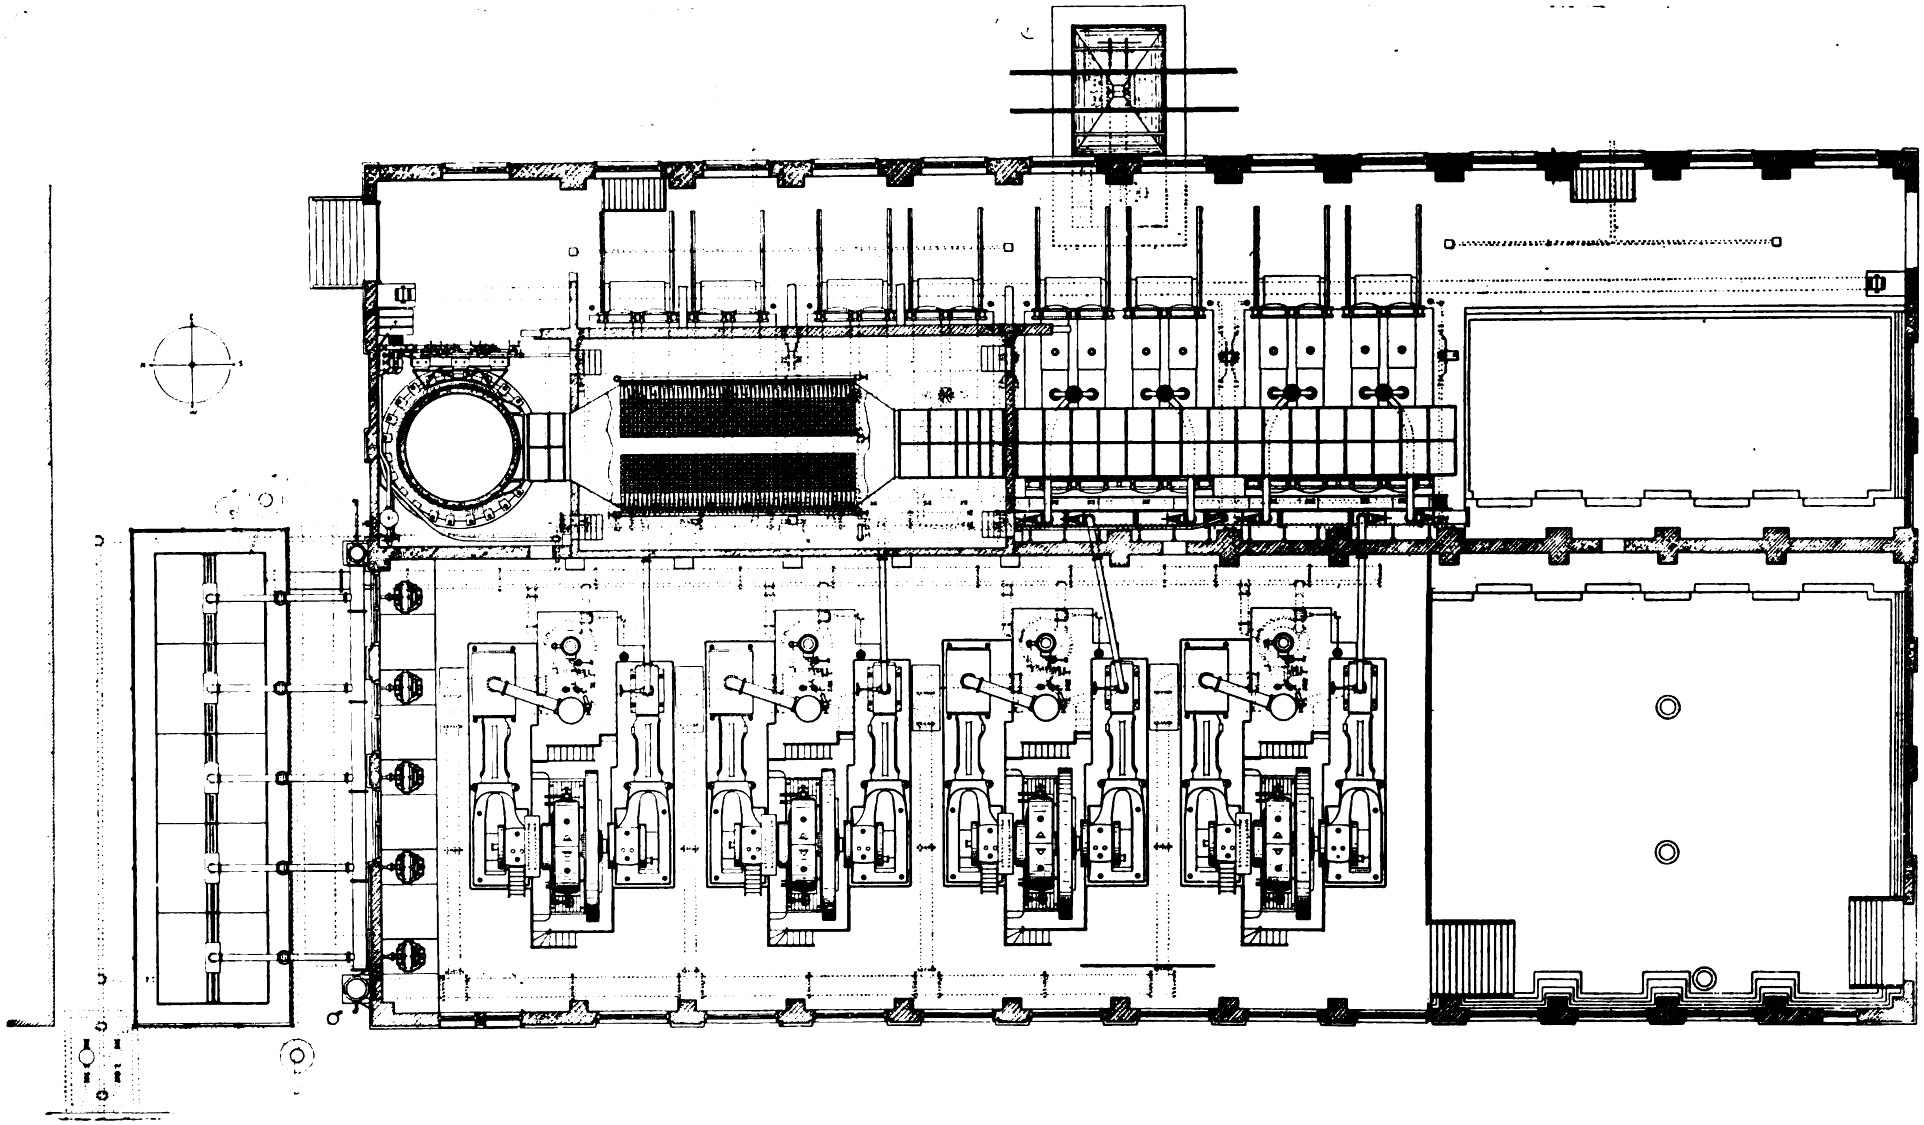

FIG. 3.—PLAN OF POWER HOUSE, SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

and trial of a six car train, the cars to be furnished by the road. Mr. Sprague then made arrangements with the General Electric Company for the equipment and tests of six cars at the Schenectady works. This test, as is now well known, took place last August and demonstrated to the satisfaction of the intending purchasers that the system was all right in principle, and with perfection as to details would be practicable. Arrangements were made for another test of a five car train on the tracks of the Metropolitan West Side Elevated Railroad at Chicago, which test took place in December and January last and resulted in the awarding of the contract for the entire equipment with the multiple unit system. The Electrical Installation Company of Chicago was awarded the contract for wiring the cars and placing motors under the Sprague contract, and was also given the contract for running the feeders.

THE POWER STATION.

The road, as will be seen by the accompanying map (Fig. 1), consists of a single route running from Sixty-third street and Stony Island avenue to Wabash avenue and Congress street,

where it joins the Union Elevated loop operated over by all the elevated roads of Chicago. It is about 8.3 miles long. At its southern end it is a competitor of the excellent suburban service of the Illinois Central. The rest of the way its chief competitors are electric and cable surface lines.

The power station shown in Fig. 2 is located at Fortieth and State streets, adjoining the structure. This is a location desirable from many standpoints. In the first place it is near the centre of distribution or load centre of the road, being approximately 3.3 miles from the northern end and 5 miles from the southern. It is also convenient to coal, as a railroad runs along Fortieth street directly past the building, and a coal siding will be run in along the east side of the power house between it and the structure, as shown in the accompanying plan and end elevation, Figs. 3 and 4. From the coal cars the fuel is shoveled or dumped into the hopper which surrounds the car as shown, and falls into a coal crusher under the coal track. This coal crusher is driven by an ironclad C & C motor. From the crusher it is taken by John A. Mead conveyors and distributed along the coal storage bins under the roof of the boiler room. From the bins and hoppers it is fed down to the mechanical stokers. Between the hoppers and the discharge pipe which delivers fuel to the stokers, is an automatic weighing device furnished by Borden & Selleck, which causes coal to be discharged 224 pounds at a time; the number of discharges being recorded, the coal supplied to any boiler is easily calculated. The mechanical stokers are of the Babcock & Wilcox make, as are also the boilers.

There are eight of these B. & W. boilers, each provided with 64 square feet of grate surface and rated to evaporate 12,000 pounds of water per hour, or 600 h. p. with an engine consumption of 20 pounds per indicated h. p. per hour. These boilers were given a cold water test of 300 pounds per square inch after being set up in the power house. For boiler feeding there are three Blake compound feed pumps, 10 x 7 x 12 inches. The exhaust of these pumps is run through a Warren Webster feed water heater. The feed water supply may be drawn from two sources—from the main engine condenser discharge or from the city water mains. In the water mains from which the station water supply is drawn, two meters are placed, and a water meter is also placed in the supply pipe of each boiler. A double system of feed water piping is installed whereby the feed water heater may be cut in or out and the Green economizers may be cut in or out. These two Green economizers are put over the smoke flue of the boilers and draw the hot gases from a point in the main smoke flue midway in the bank of boilers, and discharge into the stack just above the main flue. When the economizers are to be thrown out of use the economizer flue in the middle of the bank is closed and the smoke discharged direct into the stack. The coal conveyors as well as the economizer scrapers are driven by C & C motors. The ashes are discharged into conveyors in the boiler room basement and lifted to a bin at the top of the boiler room, from whence they can be drawn at convenience.

The stack is a riveted steel plate structure, lined with fire brick. The plates of which it is composed are ½ inch thick at the bottom and grow thinner toward the top, where they finally come down to ¼ inch. The total height of the stack above foundation is 200 feet. The diameter of the steel casing at the bottom is 19 feet, at the top 13 feet 9 inches. The fire brick lining is 9 inches for the first 57 feet, 8 inches for the next 50 feet, 6 inches for the next 50 feet, and 4½ inches for the last 43 feet.

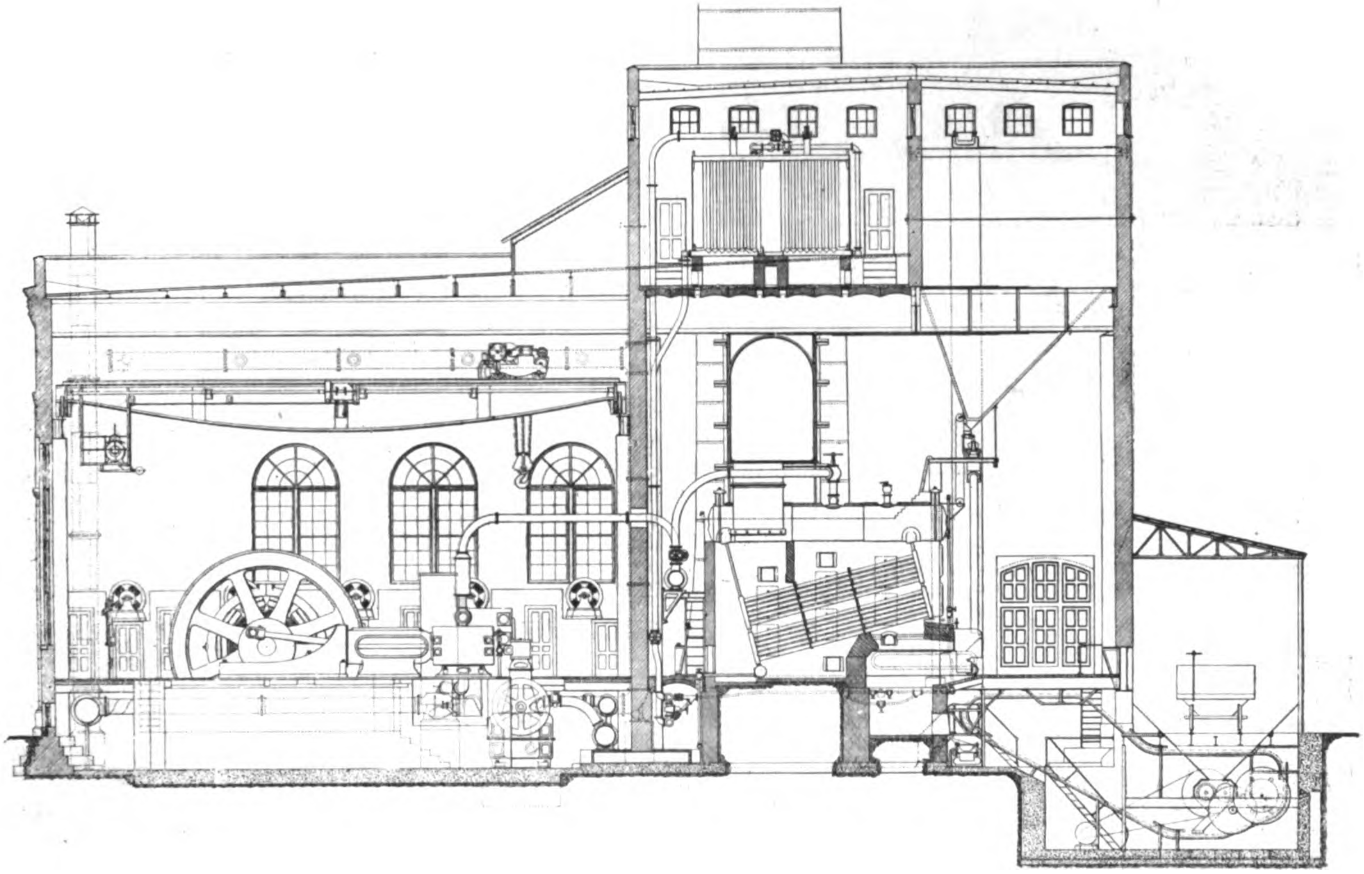

FIG. 4.—TRANSVERSE SECTION OF POWER HOUSE, SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

The boilers are piped to the main headers by 8-inch pipes. The main headers are 12-inch, of which there are two, joined at the middle by a 9-inch copper expansion bend in the middle. These headers rest on rollers supported on brackets along the wall separating boiler and engine rooms. The pipes to each of the 1,200 h. p. engines are 8 inch. Copper bends are used throughout. S. J. McLeod was the contractor for the station piping. The engine room shown in Fig. 5 contains four cross compound, horizontal, condensing, Allis Corliss engines, each 26 x 54 x 48 inch stroke. They run 80 revolutions per minute and develop 1,200 horse power at the most economical point of cut-off but will run as high as 2,000 horse power. Each engine is direct connected to an 800 kilowatt Westinghouse generator. Each engine has an independent Reynolds condenser which takes water from the tank at the bottom of the cooling tower and discharges into a 20-inch pipe which runs to the top of the cooling tower. A 30-inch free air exhaust main also

runs the length of the building. This exhaust is made of riveted steel pipe. A plain gravity oiling system is piped to all the machinery. After running through the bearings the oil passes through Turner filters and is pumped back to the tank in the upper part of the station. A Westinghouse air pump supplies compressed air for cleaning out armatures. Air is piped to each generator. A Morgan traveling crane spans the engine

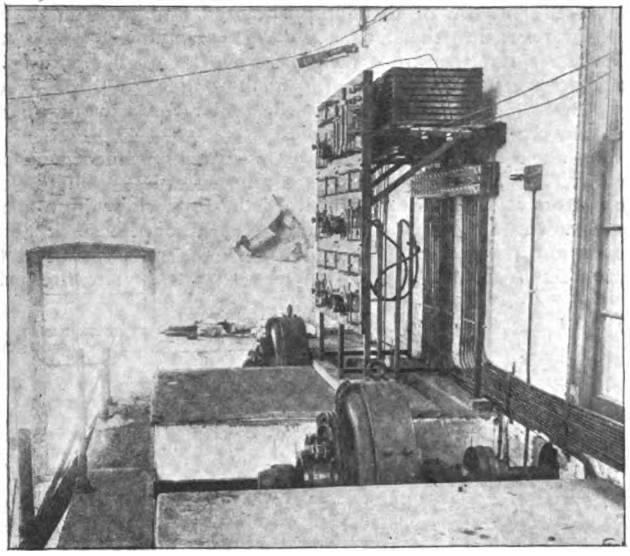

FIG. 7.—SWITCHBOARD AND C & C MOTORS DRIVING FANS FOR COOLING TOWER OF SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

room. It is rated at 60,000 pounds carrying capacity, is 59 feet long and equipped with a General Electric motor.

The dimensions of the power house are 200 by 112 feet. The boiler room is 200 by 48 feet and the engine room 200 by 59 feet. The engine room has capacity for two more units like the four already in and the boiler room will contain enough more boilers to make up for the two engines. The height of the engine room from the floor to the bottom of the roof girders is 34½ feet. There is a 9½ foot basement under the engine room. The roof girders are 4 feet deep.

The switchboard is white marble, equipped with G. E. switches and circuit breakers and Weston ammeters and voltmeters. The four generator panels are 1,500 ampere nominal capacity each and have the usual G. E. equipment of positive and negative quick break switches, ammeter, circuit breaker and field rheostat controller. The terminals of the field rheostats are on the panels but the resistance itself is in the basement. There is a main panel through which the total station output flows and this panel is designed to carry 8,000 amperes. This panel is equipped with an 8,000 ampere ammeter, a recording wattmeter, a Bristol recording voltmeter and two Weston voltmeters, one for contant use, the other to be plugged in at any generator panel before throwing that machine in. The feeder panels each are arranged to take care of two feeders. At the bottom of a panel near the floor are two single pole switches. Just above the switches is a circuit breaker; above this the two ammeters are placed and finally at the top of the panel the other circuit breaker. This arrangement has the advantage of being more compact than the usual arrangement of one feeder to a panel, but it has the disadvantage of bringing the lower circuit breakers uncomfortably near the attendant. One feeder panel of small capacity is devoted to the station motors and lights and has a recording wattmeter.

The power house is in charge of A. L. Hadin, chief engineer, a gentleman of marked ability in this line of work and formerly chief engineer and master mechanic of the Aurora Street Railway.

THE COOLING TOWER.

The greatest interest of course centres around the immense cooling tower, shown in Fig. 6, for supplying cool water to the

FIG. 9.—PORCELAIN INSULATOR USED FOR INSULATING THIRD RAIL, SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

condensers, this being the largest electric railway power house ever built to use condensing water not supplied by a natural water supply. The word immense, however, does not exactly apply to the tower that has been built, for considering the horse power it has been designed for it is remarkably compact. It is 16½ feet wide, 64 feet long and 34 feet high. Under the tower proper is a tank 6 feet deep so that the total height of the structure is 40 feet. The tower is constructed under the designs of the Wheeler Condenser & Engineering Company, known as the Barnard system. A 20-inch discharge pipe is run the length of the engine room and all the condensers discharge into it. At the end of the engine room next to the cooling tower this pipe runs vertically up the outside wall to a height of 48 feet which is 12½ feet above the top of the tower.

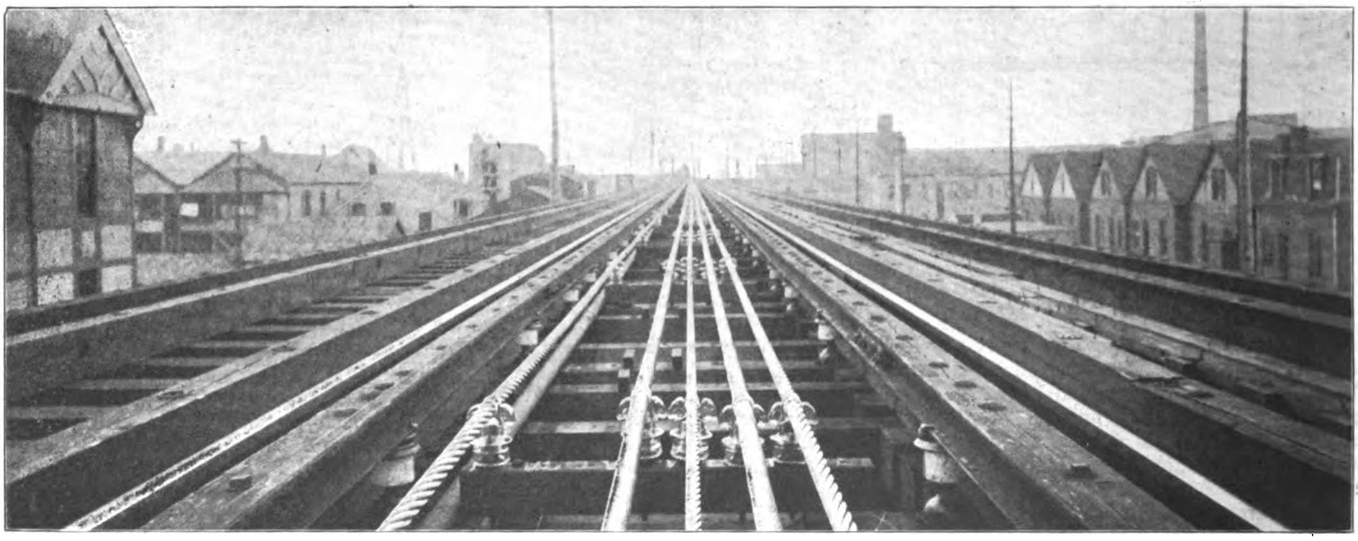

FIG. 8.—TRACK CONSTRUCTION AND LOCATION OF FEEDERS, SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

This vertical pipe is left open at the top as an emergency overflow in case the pressure rises above a certain amount in the condenser discharge. At a level with the top of the tower a 20-inch pipe leads off horizontally from the vertical discharge pipe and is supported on brackets on the wall of the power house. From this 20-inch horizontal pipe a 10-inch branch pipe is led over to the tower every 11 feet 8 inches. These

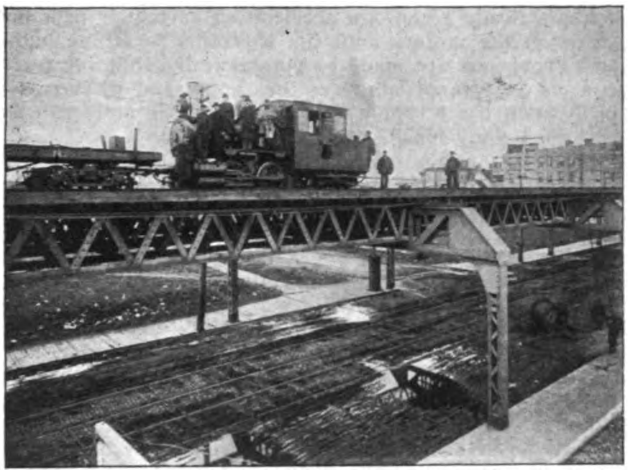

FIG. 10.—METHOD OF HAULING UP FEEDERS BY MEANS OF A STEAM LOCOMOTIVE, SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

branch pipes discharge into headers from which the water is sprayed over wire nets which are hung vertically like curtains in the tower. It then trickles down over the wire netting to the tank at the bottom during which process it cools by contact with the air and by evaporation. The tower is built of steel plate and was constructed by the Toblin & Hamler Manufacturing Company which company also made the stack. At the bottom of the tower air can be drawn in by ten 10-foot fans. Two fans are on each shaft, as shown in Fig. 6. The tower adjoins the north end of the engine room and the five fan shafts are run through into the engine room where are five 18 horse power C & C motors, shown in Fig. 7, direct connected to the shafts, and set on a gallery over the toilet rooms. The maximum speed of the fans is 175 rev. per minute. On the motor gallery is a switchboard for the fan motors at which they can be connected in various combinations of series and parallel to give different speeds. It is not expected that all the fans will be necessary except with the station fully loaded in the hottest weather. The rated engine capacity of the plant is 4,800 horse power at present and will ultimately be 7,200.

CURRENT DISTRIBUTION SYSTEM.

The standard Chicago elevated third rail system is of necessity employed to deliver current to trains as this road uses the Union loop in common with the other electric elevated roads. The third rail is located at one side of the track, as will be seen in Fig. 8, just outside the guard rail and the top of the third rail is 11½ inches above the ties. It is a 40-pound T rail in 60 foot lengths and is supported by porcelain insulators, shown in Fig. 9, every 6 feet. Every 2,000 feet the third rail is anchored to the guard rail with strain insulators. This is to prevent creeping of the third rail, especially on grades. The third rail is sectioned about 200 feet from every station so that there are approximately as many third rail sections as there are stations, but these sections are all tapped off a copper main which runs continuously the length of the road and to which all the feeders are connected so that practically the entire feeder system is tied together and the maximum benefit is obtained from the copper used. For protection against short circuits on the third rail a circuit breaker is inserted in the wire which connects a third rail section with a main. This circuit breaker is put in a box near each station where it can be easily reached by trainmen and is of the regular General Electric station type. In the box are also seven pilot lamps which show whether the

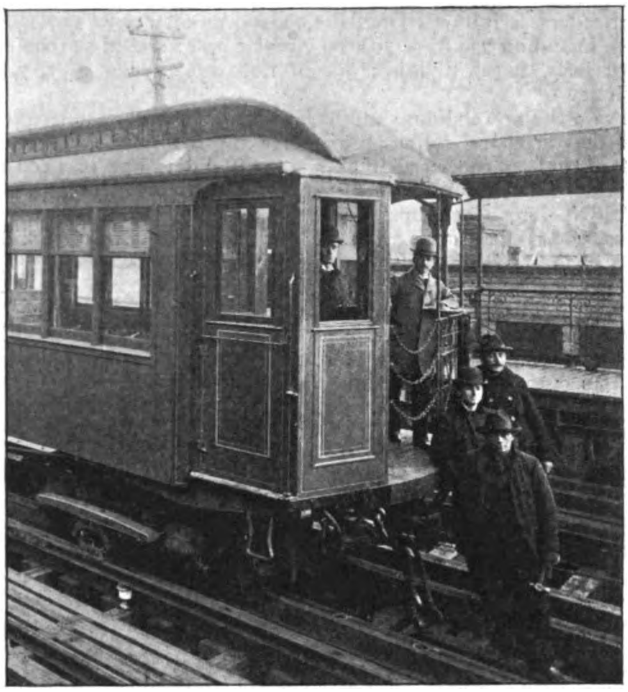

FIG. 11.—SHOWING CONTACT SHOE ON SIDE OF TRUCK AND VESTIBULE FOR MOTORMAN ON CARS OF SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

current is on the section, and a knife switch in series with the circuit breaker. The circuit breakers will be set rather high so that they will not open on any ordinary overload, while at the same time they will open so that a ground will cause no trouble outside of a short section of track. Motormen will be given instructions about closing the circuit breakers along the line and as there will nearly always be a train near a circuit breaker this plan will probably not cause many delays. The car circuit breakers are expected to take care of grounds on car equipments and the line circuit breakers are for the comparatively infrequent track grounds. It has been the policy of the engineers all through in laying out the third rail system to provide for cutting out of short sections of track and confining

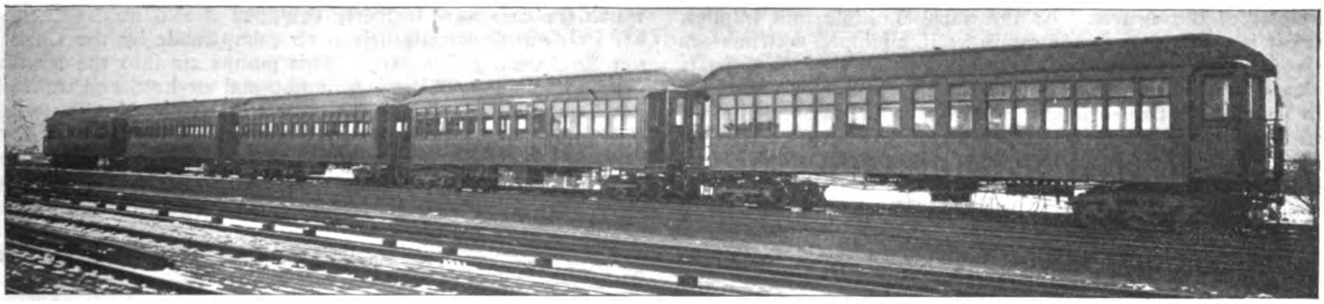

FIG. 12.—A MULTIPLE UNIT TRAIN OF FIVE CARS, SOUTH SIDE ELEVATED RAILROAD, CHICAGO.

troubles to a small part of the road. In the yards a knife switch is provided for cutting out each siding so that the third rail can be killed when current is not needed on a siding or when repair men are working around trucks. The circuit breakers along the main line afford like facilities to workmen along the main track during quiet hours.

The third rail is double bonded at each joint with Atkinson No. 0000 bonds. The track rails are bonded with the Roebling Columbia bond No. 0000. The two rails of a track are cross bonded every 120 feet and the two tracks are cross bonded and bonded to the structure every 500 feet. A riveted terminal is employed for this latter purpose.

The feeders are bare copper cable and are run in a box between the tracks supported on centre bearing glass insulators with iron pins covered with wood and wood cross arms. From the power house north, feeding 3.3 miles of double track, there are feeders as follows: One of 1,000,000 circular mils cross section, including 730 ft. of 500,000 circular mils; one of 500,000 circular mils, 16,327 ft. long; one of 1,000,000 circular mils, 7,461 ft. long.

From the power house south, feeding 5 miles of double tracks and the yards and siding, the feeders are as follows:

One of 1,000,000 circular mils 5,890 ft. long; one of 1,000,000 circular mils 10,462 ft. long; one of 1,500,000 circular mils 16,048 ft. long (including 986 ft. of 500,000 circ. mils); one of 1,500,000 circular mils 22,822 ft. long; one of 500,000 circular mils 23,122 ft. long.

The present feeder system is calculated for 120 cars. At each crossover the feeders go under the structure. In laying the feeders the Electrical Installation Company made use of a steam locomotive. The cables were drawn from a reel under the structure and the locomotive proved an invaluable adjunct in drawing through the feeders in unbroken lengths; this operation is shown in Fig. 10.

It will be seen from the description that standard line material was made use of very largely so that the cost was reduced much below what it would be if special insulators, etc., had been used.

The voltage used is 600 to 650.

In the yards at 63d street is some special work of such complicated nature that it was impossible to secure a continuous contact between the shoes and the third rail. This together with the impossibility of safely having a third rail in the shops led to the equipment of all the cars with an ingenious little rubbing contact overhead trolley. A trolley wire has been strung over the special work in the yards and in the shops. The trolley is the design of B. J. Jones of Sargent & Lundy's staff. It consists of an arch of brass rod held in balanced tension by springs at each end so that it normally stands vertical but can be deflected either way. This trolley is only 14½ inches high and the trolley wire is hung but a short distance above the car roof. When a car runs under the trolley wire this trolley yields one way or the other to the wire and no attention is required by the trainmen.

CAR EQUIPMENT AND MULTIPLE UNIT SYSTEM.

The Sprague multiple unit system which is being employed on this road has been so much discussed lately that it is hardly necessary here to give more than a brief statement as to the principles of the system. As the name multiple unit implies, each car is a complete motor car in itself, equipped with motors and controlling apparatus. The great ingenuity of the plan is displayed by the arrangements whereby the motors on the whole train may be controlled from any point on the train. The apparatus to safely accomplish this is somewhat complicated and as yet Mr. Sprague has authorized no publication of the many details and whatever articles have appeared purporting to give details have been far from correct. The general principles, however, are as follows: The motors under each car are controlled by an ordinary street car controller located under one hood of the car. This controller instead of being operated directly by a manual lever is connected to a small pilot motor. To operate a car the motorman simply controls the pilot motor circuit. In fact the whole system of train control simmers down to this one problem of properly controlling these pilot motors which work the controllers on the various cars. On each platform of every car is a small controlling box whereby the motorman controls the pilot motor circuits of the various cars. The cars are connected electrically by plug couplings. It makes no difference how many cars are in a train the motors all act in synchronism or approximately so. The rate of acceleration of a train is not governed by the motorman, but automatically. An automatic throttle governs the pilot motor in such a way that the pilot motor can advance the controller from one notch to the next higher only when the current flowing through the armature of one of the motors under cars falls below the amount for which the throttle is set. For example, if the throttle is set for 100 amperes the pilot motor will move the controller ahead a notch every time the current falls below 100 amperes so that practically a constant accelerating current is kept flowing through the motors until the controller is at the highest point. Provisions are made to automatically shut off current from a car in case of failure of the supply and to turn it on again by steps if the supply is resumed and the motorman still has his controlling handle on.

A great deal of argument might be indulged in as to the merits and demerits of the system, but time and experience will settle the question better than any amount of argument. As to the efficiency and cost of maintenance of the multiple unit system for performing a given service as compared with the performance of the same service by a locomotive or motor car at the head of the train there will naturally be considerable difference of opnion. One thing, however, must be admitted by all, namely, that it affords a traction on the drivers by distributing the motors through the train which can be obtained in no other way at present on an elevated road where the weight of locomotives is limited by the strength of the structure. This gives two advantages either or both of which may be made use of. It gives a traction on the rails which permits a faster acceleration and consequently faster schedule than can be obtained in any other way provided motors of sufficient capacity are provided; or it permits the running of longer trains than any locomotive could haul. Either one of these items may mean the attraction of enough traffic to offset any increase in operating expenses which the multiple unit system may involve. Faster schedule time means the attraction of passengers to the road and longer trains mean the ability to comfortably carry more passengers per hour if trains are already operating on the shortest permissible headway.

Just what the schedule time on the South Side Elevated will be it is of course impossible to say until the road is in full operation electrically. The guaranteed schedule of the new electrical equipment is 15 miles per hour, which is but slightly above the present steam schedule. The results will be watched with much interest.

In changing the rolling stock from steam to electrical equipment the old truck was taken from under one end of each car and a McGuire elevated motor truck substituted for it. On this motor truck two G. E. 57 motors of 50 horse power were mounted. Thus half the weight of the car body and the weight of the two motors is on the driving wheels or about 60 per cent. of the total weight. Contact shoes are mounted on each side of each truck. It was necessary also to have a vestibue for protecting the motorman on the front platform, shown in Fig. 11. A folding vestibule was designed, the two sides of which swing back against the end of the car out of the way of gate or passengers when the vestibule is not in use. Up against the front wall of the vestibule are the air brake valve, air pressure gauge and electric trolley handle. The Westinghouse air brake with which the cars were formerly equipped is still used. Each car has its own electrically driven air pump made by the Christinsen Engineering Company. This pumps air into the auxiliary reservoir under each car. An additional air hose and train pipe has been put in in addition to the regular Westinghouse train pipe for the purpose of connecting together the auxiliary reservoirs and equalizing the reservoir pressure throughout the train.

The Gold electric car heaters are used and are hung under the seats. When giving their maximum effect they take 22 amperes per car at 600 volts.

The maximum speed of the motor equipment on these cars is about 26 miles per hour.

There are 120 cars equipped with motors and 30 more cars which have been wired for electric lights, heaters and pilot motor circuits, but are without motors. These can be run in among motor cars of multiple unit trains. A multiple unit train of five cars is shown in Fig. 12.

The change of the cars from steam to electric equipment involved much more work than is apparent at first thought. It had to be accomplished without interfering with the steam service. Five coaches at a time were taken to the Wells & French

car shops where they were fitted with vestibules and at the same time the Electrical Installation Company mounted the new motors and trucks and did part of the car wiring. All of the wiring could not be finished, however, because of the presence of the steam heating and Pintsch gas lighting systems. After the road is in full electrical operation the work will be finished by removing the steam heat and Pintsch gas apparatus.

The first electric service on the road was begun with seven 3-car trains April 20, 1898. The electric trains will be put on a few at a time until the complete change from steam to electric service has been accomplished.

ELECTRIC LIGHTING

Electric Light and Power Station Records.

THE difficulty of keeping reliable records of the daily operations and output of electric light and power stations is familiar to every station superintendent. The usual method of taking readings of the different instruments at regular intervals and entering them into a log book from which curves are traced on the following day is unsatisfactory, for several reasons. With this method the amount of clerical work necessary to be done in order to produce curves that are sufficiently accurate to be of any practical value is so great that in the large majority of stations no attempt is made to keep such records.

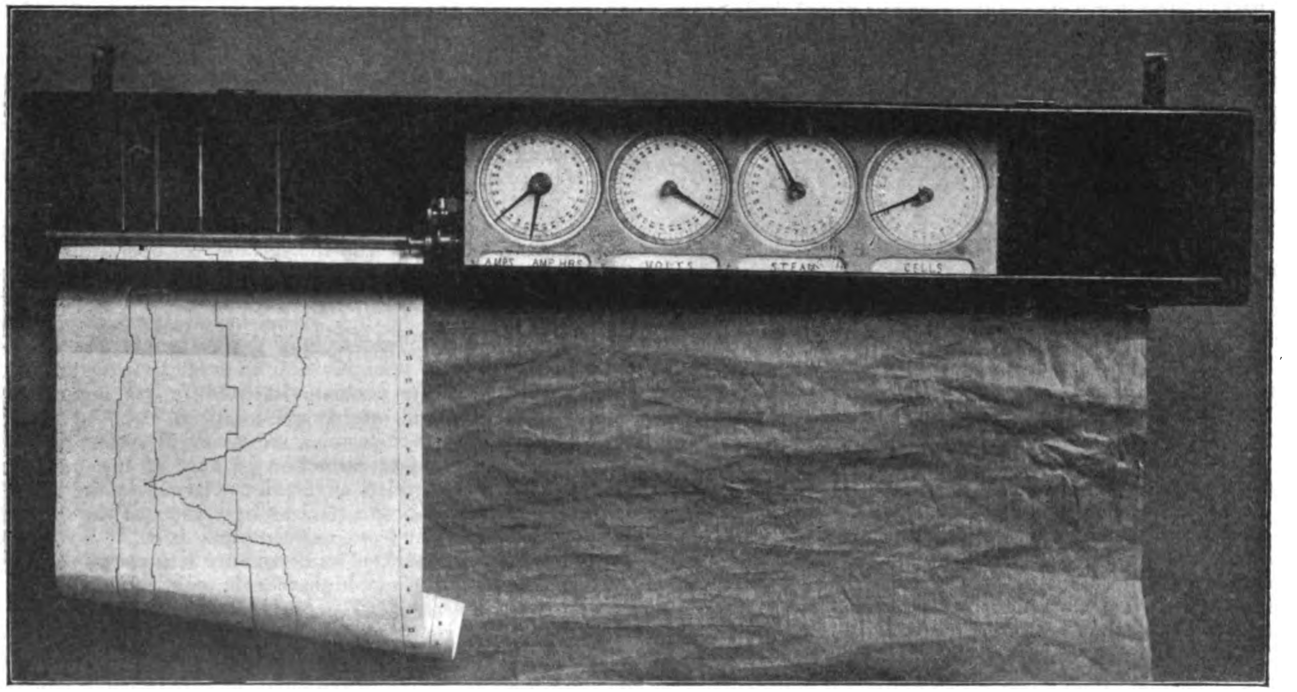
It is easy to understand why no great degree of accuracy can be expected from records kept in this manner, when it is considered that usually three or four persons are responsible for the figures representing one day's operations, and that the services of still another person are required to plot the curves from these figures. The fact, also, that a switchboard operator seldom has much experience in the duties of an accountant, and that he is obliged to use writing material one moment and an oil can or similar piece of apparatus the next, readily explains why these records frequently cannot be deciphered even by those who have written them.

The importance, however, or rather the necessity, of having trustworthy curves to show how the conditions in an electric light or power house vary from hour to hour, is so obvious that it is hardly necessary to dwell upon it. Without such curves it is impossible to have any definite idea of where losses occur or in what direction improvements should be made in the operation of the plant.

In stations where storage batteries are used it is absolutely necessary to keep accurate records if losses in current and injury to the battery are to be avoided. In such stations the switchboard operator should have constantly before him something to show what work the battery has just been doing, in order that he may be able to give the battery proper attention and make use of it to the best advantage. For this purpose curves traced in the usual manner are obviously of no service, as the occasion for which they are needed arrives before the curves are made out.

When one switchboard operator relieves another he should have the means of becoming thoroughly acquainted with all the conditions existing up to and at the time that he comes on duty. This is necessary in order that he may know what has to be attended to. To furnish this information, the records should be complete up to the time that he takes charge, and arranged in such manner that a person familiar with the work can understand the whole situation at a glance. This latter point is important, because a switchboard operator usually has so much to attend to that he cannot devote much of his time to finding out what has been done by those who were on duty before him.

The apparatus represented in the accompanying figure was designed for the purpose of diminishing, to some extent, the amount of bookkeeping necessary to be done in connection with station records. The method of operating the instrument is somewhat similar to that of operating a cash register. Its construction can be readily understood by reference to the cut. The sheet of paper on which the records are to be made is drawn forward between two rollers by means of a small lever and ratchet on the end of one of the rollers. A number of pencils, corresponding to the number of curves desired, press against the paper and trace the curves as the paper is drawn forward.



MACRAE'S APPARATUS FOR KEEPING ELECTRIC LIGHT AND POWER STATION RECORDS.

Each pencil can be set in any position relatively to the width of the paper by means of a gear wheel engaging into a rack fixed to a tube on which the pencil is mounted. The shaft on which this gear is fixed is provided at one end with a pointer, which moves over a divided scale, and at the other end with a small hand wheel, by which the pointer and the pencil connected with it can be set in different positions. These hand wheels are not seen in the figure, as they are on the ends of the shafts, which pass through the bottom of the case.

Each time the readings of the different station instruments are to be recorded the dial indexes connected with the pencils are set to the points corresponding to these readings. The lever operating the paper is then drawn back against a stop and released. This forces the paper forward a definite amount and

each pencil adds a corresponding amount to the curve that it is tracing. A type wheel attached to one of the rollers prints at the same time the hour of the day on the margin of the paper. When, as in the case of ampere hours, a time dimension enters into the quantity of which a record is to be made, the dial is provided with two index hands mounted on one shaft, in the same manner as the hands on a clock dial. One of these indexes, which we may call index No. 1, is fixed on the shaft and marks the position of the pencil which traces the curve. The other, or No. 2 index, is connected to index No. 1 by means of a clutch in such a way that when index No. 1 is moved forward it brings No. 2 index along with it, but when index No. 1 is turned in the opposite direction the clutch is released and index No. 2 does not move.

Each time that No. 1 index is to be set for a reading, it is first moved back to zero and then brought to the position in which it is to remain until the next reading is taken. By this operation No. 2 index is made to integrate the curve traced by the pencil connected to index No. 1; for example, if the pencil is tracing an ampere curve the reading of No. 2 index will be the number of ampere hours represented by that curve. In order that the reading of No. 2 index may represent ampere hours directly, the relative rates at which the indexes move over the dial must be determined by the number of readings taken per hour; for instance, if five minute readings are taken No. 1 index should pass over 12 scale divisions while No. 2 index is passing over one division. If, however, there is occasion to take readings of any other frequency, without altering the ratio of the gears connecting the two indexes, a reducing factor must be employed in connection with the dial indications.

The part of the paper containing the curves of one day's operations can be cut off and filed away in the regular manner, or the paper may be wound on another cylinder until the whole roll is used up.

Statistics on English Electric Lighting Plants—III.

(Concluded.)

BY CLAUD P. D'OYLY.

THE incorporated companies are in many cases close corporations, and as in the case of the companies over here, do not offer to sell stock, and it is consequently hard to get an idea of the value of the same; but of eighteen companies which are quoted in the financial papers, organized to furnish light and power, the common stock is worth par on a basis of dividends of 3.3 per cent.; that is to say, stock of a company which pays 6.6 per cent. is worth 200.

In many cases the value of stock never comes to be considered at all unless it be at a time when the corporation makes an attempt to buy the plant or in the settlement of an estate or in an attempt to buy out the "founders' share." A recent case of the latter is the Metropolitan Electric Supply Company, which is paying regular dividends on the different classes of stock, and is likely soon to have a surplus to pay to the holders of founders' shares.

It might be mentioned incidentally that in the organization of the company, the subscribers to the preliminary expenses received founders' shares on which no dividend is to be paid until all the other shares are on a certain dividend basis—in this case 7 per cent.—when the surplus to be divided up goes one-half to the ordinary stockholders or surplus fund, and the other half to the holders of founders' shares.

The Metropolitan Electric Supply Co. offers to holders of founders' shares for each share 140 shares of common stock, paying 6 per cent per annum. The holders want 300 times the amount held in new stock, and as the stock is worth 220, par 100, they would be getting 660 times their original investment. The company offers 308 times the original investment to obtain these founders' shares (100 shares, par $50). Two other London companies had to buy out their founders' shares at a cost of $600,000 for one company and $750,000 for the other.

Engineers are constantly on the alert for improvements looking to a gain of efficiency in the different parts of the system. The money necessary is a very secondary consideration, and consequently manufacturers in England make a very high efficiency machine—a great deal higher than is ordinarily made on the Continent of Europe or as standard machines in the United States. Many of the manufacturers make 80 k. w. generators, of which they guarantee the efficiency to be upwards of 95 per cent. This makes the machines heavy, and they do not look symmetrical, and they require movement of the brushes with the variations of load, a point which would instantly condemn them in America. English manufacturers have not made many 550-volt generators of any considerable size, and consequently have not had any experience with "bucking." When they have experienced this, they may aim at machines with a larger air gap and a lower efficiency, more after American practice, but which machines will take care of themselves. In the general run of specification, great stress is laid on the efficiency at different loads, and the $\frac{\text{E. H. P.}}{\text{I. H. P.}}$ is a point on which great stress is laid by the consulting engineer by whom the plant is to be accepted; and the amount of attention required at the switchboard and brush-holder is of small importance. This is the natural result of having cheap assistants to look after the details in the station. The average mechanic or laborer in England gets about one-half the pay he would get by crossing the Atlantic; but the man who has had a technical education, and who has a good knowledge of construction work and keeping the plant in operation would probably receive four times as much pay on this side of the Atlantic. A good fireman would receive very little more for skill in working on his fire than a day laborer, although no one has a better opportunity to save money.

A machine which is having a good run just now is the "rectifier," which takes alternating constant potential current and transforms it into approximately direct constant current. These machines are very sensitive and require rather delicate adjustment, but they show an efficiency of 89 per cent. at one-quarter load, and run up to 96 per cent. at full load. When you compare this with the constant current arc generator with an efficiency of 65 per cent., it is quite a contrast. Besides the gain of efficiency in the rectifier itself, there is the gain of efficiency caused by increasing the load on the alternator. A good many plants are also using, at present in a rather small way, cut-outs for transformers, to save the iron loss during the hours of light load. For any one who has noticed the loads on alternating stations in hours of broad daylight, this matter has much interest, but no one seems to have solved the matter in a really practical way, as the tendency of the insulation to break down is one point of great difficulty, and the size of the apparatus must be moderate, and the certainty of operation, especially in the matter of cutting in the transformers, must be absolute, and the mechanism should not require any more inspection, especially if it is to be put in out-of-the-way places in transformer vaults or on poles, than a transformer or fuse block. It has been mostly scientific and theoretical investigators who have worked on the problem—it has not yet come into the hands of the practical mechanical engineer.

All these different economies and the rigid system of accounts has enabled a constant reduction of cost of the k. w. h., so as to lead to a reduction of the sum charged to the customers. Some of the metropolitan stations have reduced the cost of distributing the current from ten cents per k. w. h. to four cents in five years; but much of the economy is through the increase of customers, bringing higher economy of machinery and smaller fixed charges per k. w. sold. This has in most cases been done in economy outside of the coal pile, as the climate exercises a bad effect on the variations of the load and alternating plants having no storage batteries suffer the most. Metropolitan stations must always be prepared for fogs, which drop down without any warning and instantly cause the load to be multiplied by 10—and in alternating plants this means having many boilers fired up ready for an emergency of this kind. Other cities have climatic changes which demand about the same coal expenditure, but not in the same degree. Coal is an item which is not very easy to save, providing the management is efficient, and it is the poorest thing in which to make comparisons. The price varies between $2 and $5 per ton, depending a good deal on the distance from the coal mines and the calorific value of the coal. The best results obtained in any plants in England in the amount of coal consumed per k. w. h. sold is 6.2 lbs., and there are several companies which come near this mark, of very widely varying outputs. The largest in the matter of outputs is the Westminster Company, which sold 3,600,000 units in 1897. The second is the St. James station, which furnished 2,500,000 units at the same expenditure of coal per unit. At about the same coal consumption per k. w. h., but furnishing only 514,000 units, the Oxford Company stands well. Kensington and Brighton stand about the same as regards fuel consumption per k. w. h. sold, 6.25 lbs.

Kingston-on-Thames uses 25 lbs. of coal, but of very poor quality, per k. w. h.; and it costs 3.24 cents per k. w. h. The total k. w. h. sold was less than 200,000.

In Scarborough, another town which sold only 200,000 k. w. h., the cost for coal was 2.58 cents.

It is strange how Oxford, selling 500,000 units, can generate the current with 6.25 lbs. of coal per k. w. h., and no other companies can beat it, although you would look for some one of the companies outside of the metropolitan area of fogs to do it.

The electric lighting art has not been developed to the same extent in England as it has in the United States, and although they are making some headway now and are doing it in a thoroughly systematic way, it will be a long while before they can catch up with us, as after all the larger towns are lighted up, then the question comes up which was tackled here years ago, of the small towns which are too small for gas works, and which were equipped with overhead wires in America, but which cannot be done in England unless new Board of Trade regulations are passed.

TABLE IV.

Works.	Cost in cents per unit.	Units sold.
Bradford	2.06	820,000
Brighton	2.88	1,400,000
Edinburgh	1.26	1,700,000
Glasgow	2.64	1,600,000
Leeds	1.60	800,000
Liverpool	2.28	850,000
Manchester	1.88	2,800,000
Portsmouth	3.25	620,000

Table IV. gives the cost of fuel, oil, labor and repairs and maintenance expenses, as works cost, and it shows the variation in different plants with somewhat similar output. These are all very low, but all vary in conditions as regards system of distribution, kind of engines and generators, boilers, etc., although some manufacturers claim low works cost through using their particular kind of apparatus. The increase of the plants is the strong feature which has brought up the high efficiencies.

Protection for Edison Three-Wire and Other Balanced Systems of Electrical Distribution.

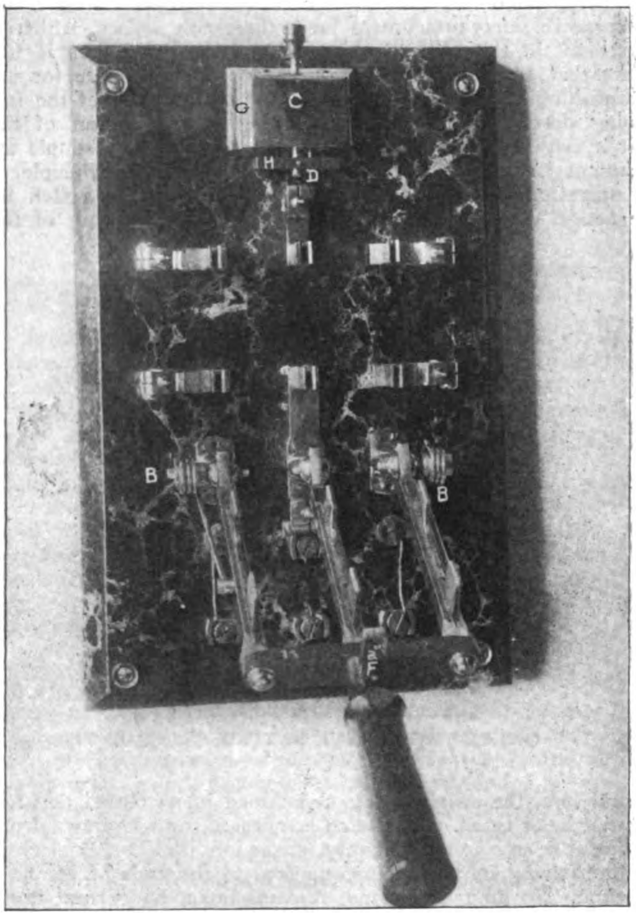
BY EUSTACE OXLEY.

It is well known to electrical engineers that the blowing of the fuse on the neutral wire of an Edison three-wire system is often the cause of disastrous results to the lamps, and to the wiring, as well as to other translating devices that may be connected. These results are due to the sudden and considerable increase in potential upon that side of the system having the smaller load, such increase being produced by opening the neutral, or balancing wire, by the blowing of its fuse. The increase in potential from this cause, upon a three-wire system, may reach a point where it is almost double the voltage that should normally exist, and such a rise is not unusual. Evidently, incandescent lamps, as well as motors and other apparatus constructed to operate under a pressure of only 110 volts, and which are suddenly subjected to nearly twice that potential, are unable to resist a strain that they were never intended to undergo. It is not surprising, therefore, that their complete destruction, or serious injury, should be the unavoidable result.

Under such circumstances, the blowing of the neutral fuse is usually followed by a rapid increase in the illuminating power of the incandescent lamps upon the under-loaded side of the system with a corresponding loss in those lamps on the other side that are in circuit at the time, and then by the bursting of the former, their rupture being accompanied by a loud report, and the scattering of shattered glass. These results, which speedily follow the blowing of the fuse, are of such nature as to produce an extremely startling effect upon those who happen to be present at the time of such an occurrence; while in the minds of those who, from ignorance, fail to comprehend the nature and cause of these disturbances, it is not strange that they should produce a strong and permanent prejudice against the use of electric energy.

So far as the injury to the system is considered, the lamps, even if they escape complete destruction, are so severely strained by the abnormally high potential to which they are exposed and the excessive current forced through them, that their candle-power, as well as their term of use, are largely diminished, and the injury is usually so serious that their immediate removal and the substitution of new lamps is expedient. The damage to the incandescent lamps may represent, by itself, a considerable expense to a generating company, upon which these losses fall. When fan-motors, or enclosed arc lamps, or both, as is frequently the case, form part of the translating devices, the figures representing the financial injury will often be largely increased, and in the latter class of cases the loss will fall upon the consumer instead of the distributing company.

Not long since a disturbance of this character occurred in a large Government building in Washington, the neutral fuse at the main service block blowing at a time when the number of lamps on one side of the system was considerably in excess of those upon the other side. The latter were subjected to a large increase in potential, which was not, however, so high as



OXLEY PROTECTIVE SWITCH, OPEN.

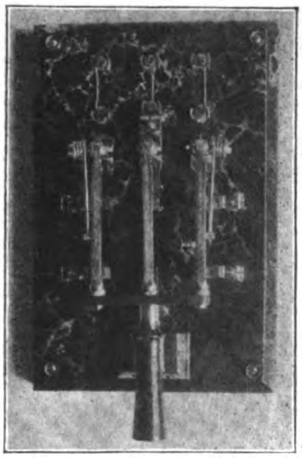
to burst the bulbs. They burned a few moments with a great increase of illuminating power, after which the filaments gave way and the lamps burned out.

Another instance occurred, not far from the same date, in the Bureau of Engraving and Printing in the same city, where about thirty-four enclosed arc lamps are installed on the Edison three-wire system, and supplied with current from the street mains. At the moment when the neutral fuse gave way, eighteen of these lamps were burning on one side of the system, and six on the other side. These six lamps were burned out, and their removal for repairs was the cause of serious inconvenience to the Bureau, as they happened to be located in the printing division, where the work was heavy and in arrears. Many other instances, in private as well as in public buildings, could easily be named. Central station men cannot fail to be aware of their frequent occurrence, and of the annoyance and damage that are the direct results. The over-fusing of the neutral wire, which has come to be a common practice among wiremen and others, came into existence, and owes its prevalence to the fact that it has been, heretofore, the only

known expedient for avoiding disturbances of this character. This practice of over-fusing the neutral is directly contrary to the rules of the Board of Fire Underwriters, but it is probably much more common than is generally known. If the fusing of the neutral wire corresponded, in all cases, with the requirements, the occurrences described would doubtless be greatly multiplied in frequency.

There is a far more serious menace to property, however, in the fact that the abnormal tension on the underloaded side of the system, upon the blowing of the neutral fuse, develops weak spots in the wiring, or if such places already exist, the insulation quickly gives way, under the strain, and destructive fires may be the direct result. Combustible material, favorably located, is all that is required to begin a conflagration, the results of which may be widespread.

To remove the possibility of such disturbances occurring, and the dangers that may, and undoubtedly do, follow therefrom, as well as to eradicate the pernicious practice of over-fusing the neutral, by removing entirely the causes which have led to and perpetuated this evil, the writer has devised a simple and inexpensive safety-attachment for a three-pole switch, which is illustrated in the accompanying cuts. As the writer is not aware that any means have been proposed heretofore for accomplishing these important results, it is thought that the following description of the construction and operation of the switch may be of interest. The device consists of a simple attachment for an ordinary, three-pole switch. The principle of its operation consists in automatically opening the switch by the action of a spring, immediately upon the blowing of the



OXLEY PROTECTIVE SWITCH, CLOSED.

neutral fuse, the switch being maintained in its closed position by a latch, or catch. This latch is released, or withdrawn from its locking engagement, by the attraction of a small electro-magnet having its terminals connected to the ends of the neutral fuse. So long as the fuse remains intact no current flows through the windings of the magnet, as the potential at its terminals is only that due to the drop in voltage in the neutral fuse itself. Upon the blowing of the fuse, however, the potential between the points of connection immediately rises, causing current to flow through the magnet coils, thus energizing the magnet sufficiently to enable it to release the latch. Although the winding of the magnet is in multiple with the neutral fuse, it does not in any degree affect the carrying capacity of the latter, since the resistance of the coils is so great relatively to that of the fuse, as to prevent the flow of current in said coils as long as the integrity of the fuse is maintained.

The switch illustrated in the cuts is normally opened by the springs B, and is locked in its closed position by a latch, or catch C, which consists of a small pin D, which is movable longitudinally. Its end engages a recess A in a hanger F, on the handle of the switch, and is thrown into this engagement by a light spring, coiled on the pin D. The end of the hanger F is beveled to retract the pin as the switch is closed.

The magnet releasing the latch is placed in a strong brass housing, or box, G, by which it is wholly enclosed and concealed, the pole pieces only projecting through one wall. Upon the pin D, which lies between the cores, is mounted an armature H. When the neutral fuse blows, the armature, which is suddenly attracted, releases the latch, thus allowing the switch to be opened by the springs B.

This automatic opening of the switch is so nearly coincident with the blowing of the neutral fuse that a secure protection is afforded against all possible injury to the wiring, lamps, or other translating devices, and every chance of fire being caused by such an occurrence is very completely prevented. The ends of the winding of the electro-magnet are carried in channels upon the back of the switch-base to a point where they can be connected to the terminals of the neutral fuse. The switch when closed is retained in that position by the latch-pin D. It may be instantly released, however, by simply drawing the latch-pin with the finger, when the springs throw the switch open with a movement exceedingly rapid. The parts are all restored to normal position again by simply closing the switch until the latch-pin can enter its locking recess. The opening of the switch follows so closely upon the blowing of the fuse that it is practically impossible to distinguish the interval which separates the two occurrences.

TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work—VIII.

BY A. E. DOBBS.

IN turning corners, two poles should be used and placed close together, and in such a position as to break the angle as much as possible. Fig. 26 shows how this is commonly done. The use of double arms on the corners is to be commended, as it relieves the strain on the corner pins, and to a great extent on the pole itself, by distributing the pressure more equally.

In the illustration the arms are shown faced in line with the apex of the angle instead of at right angles to the street. This does not seem to be a matter of much importance, but a practical experience has shown that this is the best way, as the strain is against the arm in the line of greatest resistance, therefore

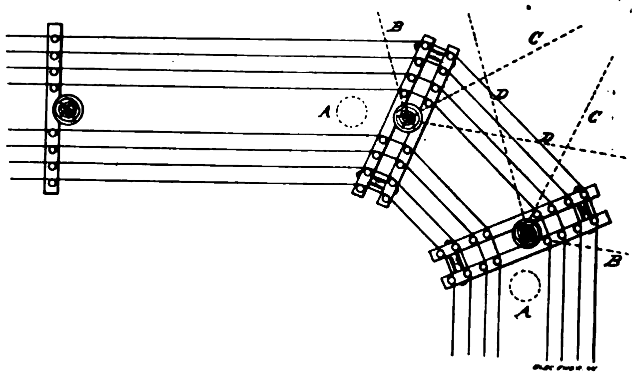


FIG. 26.

relieving the tendency to warp. It also turns the corner on two pins instead of one, as would be the case if square with the street. It may be objected that the wires, as they approach the corner pole, are thrown closer together. Well, the difference will not be much, but it can be avoided by the use of a longer arm. Suppose that the arm shown at the left in Fig. 26 is the ordinary 8-foot 6-inch short arm; by simply using 10-foot arms the lines will be kept at the same distance on the angle as on the straight line. It will not be a great deal of trouble to carry a few long arms in stock for this purpose.

CORNER AND JUNCTION POLES.

Fig. 27 shows the details of a double arm used at a cable or terminal pole. As wires from such a pole are liable to break off in at least two directions, double grooved glass, or better still, the heavy transposition glass should be used.

A, cross section of pole; B. B., arms; b, 5/8 bolt of the required length; c, block to keep the arms at their proper place—gas pipe is sometimes used for this purpose, in which case use a large washer under its ends to keep from cutting into the arm. Again

there are places where a single 5/8 bolt will not hold the centre, but that can be varied to suit the circumstances.

Another device is that shown in the second figu-e, which sometimes takes the place of the block, c. It is simply a bolt with long threads at the ends. A large nut inside the arm allows of any desired adjustment, while the nuts on the outside clamp the arms firmly in place.

t t′ t″ (both figures) shows method of lashing pins together. Make a loop, t, with No. 12 wire, then twist together as in t′ t″. This will hold the pins firmly in place against the pull of the wires.

Some men, however, prefer the figure 8 style, as shown in the first figure, g. g. The ends are passed around both insulators in the form shown, but it does not make so neat a job as the other.

What is known to linemen as buck arms, at junction poles, are not desirable, but sometimes necessary.

The form shown in Fig. 28, however, should always be

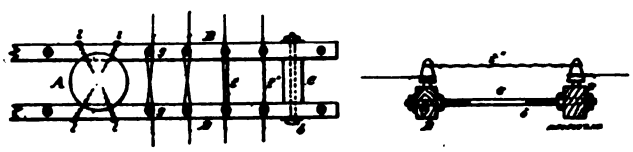

FIG. 27.

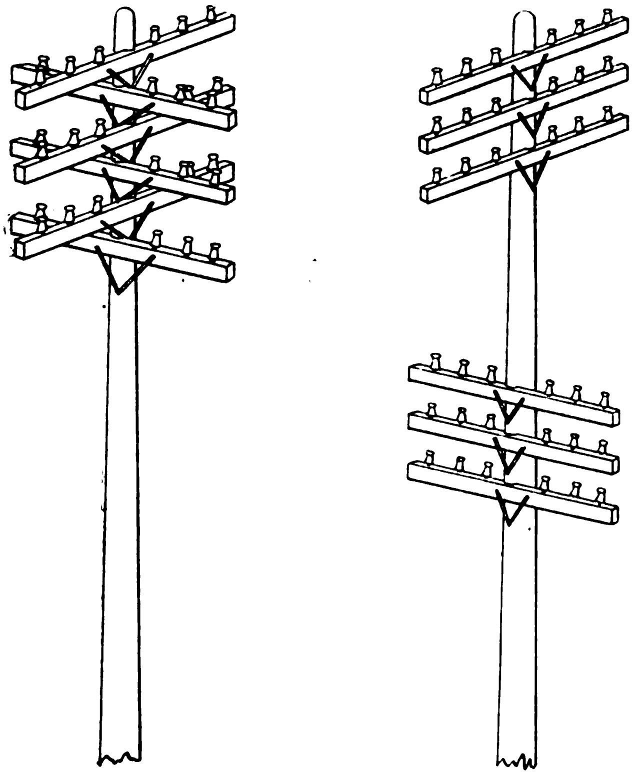
avoided, as the wires cross each other like sticks in a crow's nest, making it impossible for men to get through and do any work, without making trouble. A much better plan is that of Fig. 29, provided room enough is left for more arms on the top section. This should be done even if it is thought that there will be no more arms up there, for this telephone business has a way of growing like Jack's beanstalk, and new companies should always expect about four times as many wires as they start in with, and it is always well to have room enough. Good work does not cost a great deal more than the other kind, and is much cheaper to maintain.

Still there are cases where it is necessary to have the buck



FIGS. 28 AND 29.

arms as high as the others. The use of a cable would avoid their use altogether, but this cannot always be done. In the side elevation as shown, Fig. 30, iron or steel strips, S S, are used to hold the arms rigidly in place and afford mutual support. These strips are 1½ by 3/8, and are long enough to reach all the arms. As these arms will be doubled, two strips on each end, or four in all, will be needed. They should all be bored exactly alike, and clamped together with bolts reaching through the arms and blocks. The buck arms, B B, are put out between the third and fourth pins, and bolted down to the others. In order to afford them support, strips should be run from near the ends and bolted back to the pole with a short lag. These strips may be iron, 1 inch by 3-16 inch, or they may be rods, or even two No. 6 wires twisted together. Whether strips, rods or wires are used, they should be raised high enough to clear the wires on the lower arm. It goes without saying that double groove glass should be used on the main arm, and the wires pull

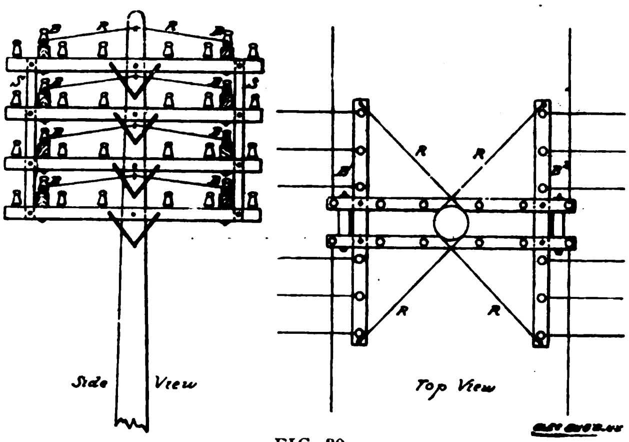


FIG. 30.

off from the lower groove, while the tops are lashed together. If necessary for wires to cross from one buck arm to another, use insulated wire and pass through the double arms from one to the other. A junction pole rigged up in this manner will always leave room enough for the men to work around it and keep the wires clear much better.

In Fig. 31 are shown methods of bracing arms on curves when double arms are not used. The lower figure shows the use of ordinary braces bolted to the arm and united at the pole by a single lag screw or bolt, the same lag going through the large hole of both. That shown in the upper figure may be of strap iron or No. 8 wire passed around the end of the arm and neatly twisted together.

GUYS.

In Fig. 26 it will be noticed that there are several dotted lines running in different directions, to indicate the possible position of different guys. As the wire turns a corner the natural tendency of the pole is to slip back towards the centre of the longest span, and if left free to move longitudinally, that is where it would go, but as it is fastened at the ground it cannot move back more than four or five feet, which would be about the spots marked, A A, provided that the only guys were the side guys indicated by the dotted lines, B B. Therefore, if the line

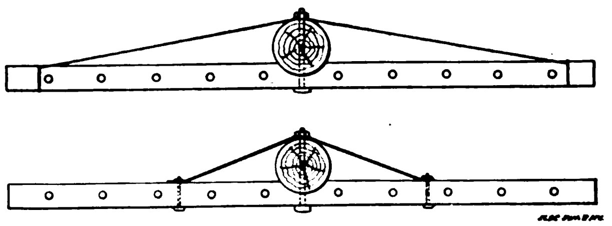

FIG. 31.

must be side guyed in this direction, it will be necessary to put on other head guys, in the direction of D. D. If, however, a stub can be so placed as to pull off in the direction C C, no other guys are needed, as this answers to both head and side guys. If the poles are close together, one stub will sometimes be sufficient for both Remember that these stubs should be well anchored.

SCRANTON, MISS., is installing a 75 h. p. Ball engine, built by the Ball Engine Co., Erie, Pa., to be direct connected to General Electric dynamos.

Vol. XXV. NEW YORK, MAY 5, 1898. No. 522.

An Admirable Exhibition.

NOTHING stales the infinite variety and charm of electricity, and the present Electrical Exhibition only goes to show how numerous are the opportunities of presenting features of genuine interest and merit. We print elsewhere in this issue not only a full report of the brilliant and memorable opening exercises, but plans of the exhibits and some further notes, in brief form, on what is being exhibited. Any one can see that the work of two years ago, altogether admirable as it was, has been exceeded, and the appeal of electricity to the public driven home with even greater emphasis and effect. Outside the very fine commercial and industrial exhibits, the special features are numerous and effective, some of them highly novel. There would have been more had not the management and its committees already used up every inch of space that could be availed of for such purposes. When we consider that all this has been done in times of war, the wonder of it grows. The fact that there is war may be a lame excuse for the non-participation of some concerns unfortunately left out; but as we have said before, it seems to us that all would welcome such an exhibition not merely as a duty and privilege, but as one of the best means to help build up new arts and create new trade.

It is a little early to speak more than generally of the exhibits themselves. Many of them are really superb. Those of the Worthington pumps, for example; of the New York Edison Co.; of the New York Telephone Co.; of the Edison phonograph interests; of horseless vehicles; of the Sprague, Excelsior, Walker, C & C, Fort Wayne, Crocker-Wheeler, Eddy, Paragon, Bullock, Ziegler, Card, Safety, Roebling, Electric Storage Battery Co., are all remarkably fine; while the corresponding steam engine oil engine, and boiler exhibits in the basement are no whit behind. We commend them all for careful inspection and study. We may mention with special praise the operative street car exhibit showing the application of the underground trolley, on a regular stretch of track, with a Stephenson car, Walker motors, and all the plow and circuit mechanism in full view. As a method of showing everybody how the thing is done, this could not be surpassed. High praise of the same kind is deserved by the lovely McIntire "arcolier," and by the "magnetic" exhibit, which includes Mr. Edison's ore separation and seven-ton rocks, on the practical side, and Mr. Schoonmaker's beautiful demonstration of the field of force, on a large scale, on the scientific side.

And so one might go on, but we should soon drift into a long catalogue of interesting features. That every one will be delighted with the artistic Moore chapel, and its lighting by vacuum tubes, goes without saying. There is much educational work attempted at the Exhibition, and it will be instructive to note how the public takes to the method of combining wax tableaux and books about the periods illustrated, as a new style of making scientific study popular. We are ourselves of the opinion that they, with the popular lectures to be given, will do much to give a further hold of electricity on the public mind as a thing worth looking into and as an agency so all pervading as to be that about which, above all others, an intelligent man or woman ought to know something.

Thermo-Electric Batteries.

FAR-REACHING and full of promise as is the question of how to obtain electricity direct from coal, broader and therefore more inviting still is the problem of the direct production of an electric current by the application of a source of heat. In the solution of this problem it matters not whether a change of chemical, physical or magnetic conditions is brought about or what materials or methods are employed to arrive at the desired end. Countless have been the investigators in this attractive field and innumerable have been the methods devised for accomplishing a purpose which holds out to the successful experimenter both fame and wealth. One of the most indefatigable experimenters with thermo-electric batteries and one who has always upheld the theory that the electrical energy produced in cells in which heat is applied is primarily due to thermo-electric, and not a chemical action, is Mr. C. J. Reed. To prove this fact Mr. Reed has performed numerous experiments in the past few years and his latest apparatus was described by him in a paper read before the A. I. E. E. on April 27. The apparatus consisted of a fused mass of caustic potash or soda maintained at a temperature of from 500 degs. to 800 degs. C., into which two conducting rods are inserted, both of the same metal, and as nearly alike as possible in every respect except form. One of the rods is of cylindrical form; the other is in the form of a cylinder having a deep recess cut or turned out near one end, leaving at the end a short cylindrical head attached to the rod by a very narrow stem. With this arrangement, therefore, he has two pieces of metal as nearly alike as possible, in chemical composition and molecular structure, subjected to the same conditions in all respects, except that the temperature of one at its junction with the electrolyte is higher than the temperature of the other at its junction with the electrolyte. In other words the electrolyte has one hot and one cold junction with pieces of the same metal inserted in it to the same depth and subjected, so far as known, to no other disturbing influences. This arrangement gives an electromotive force varying with the temperature and constitution of the electrolyte between —0.2 volt and +1 volt. Mr. Reed referred in detail to the experiments of Liebenow and Strasser, pointing out the close relation which exists between the electromotive force and the temperature of the electrolyte. He claimed that the development of an e. m. f. cannot be the result of chemical action, but that the rods evolve electrical energy and exhibit a high e. m. f. under circumstances that are identical in all respects, except temperature, and that the action is, therefore, thermo-electric.

In the discussion which followed the reading of the paper, Mr. Steinmetz argued that the great change in e. m. f. due to a comparatively small change in temperature when the alkali became dehydrated, indicated a chemical action. This he believed was due to the greater affinity of the hotter rod for the oxygen than that of the cooler one, and that therefore more energy would be developed at the hotter electrode than at the cooler one. He believed that the heat energy was first transformed into chemical energy, similar to the combination of hydrogen and oxygen by means of heat, and that this chemical energy was then transformed into electrical energy, the operation performing a complete cycle. This theory, Mr. Reed replied, was neither proved nor disproved by his experiments, but they did show that the source of the energy was heat. Mr. Mordey, of London, prefaced his discussion by a few remarks in which he thanked the members of the electrical profession on this side, for the many kindnesses shown to him during his visit to this country. He expressed the opinion that chemical action must take place in the cell at that high temperature, especially as there is a difference of temperature between the two electrodes. Mr. Mailloux brought out the fact that if molten lead be substituted for the fused electrolyte, the e. m. f. would be considerably lower. This may be due to the greater thermal conductivity of the molten metal, which prevents the establishment of as great a difference of temperature as is possible when the fused alkali is used. The discussion, which might have been continued in-

definitely but for the lateness of the hour, seemed to point to the fact that, regardless of the simplicity of Mr. Reed's experiments and apparatus, there still exists a great deal of speculation and uncertainty as to the source and cause of production of the electrical energy. The subject is one still open for discussion, and one on which more thought and labor can be most profitably spent.

English Experience with 220 Volt Lamps.

THE 220 volt lamp, ushered in a short time ago, with great expectations on the part of the central station man and consumer, seems to possess some inherent faults which, if not remedied, may check its rapid introduction. The faults and difficulties of manufacture of the high voltage lamp are clearly pointed out and remedies suggested by Mr. Binswanger Byng in a valuable paper read recently before the London Institution of Electrical Engineers. The lamp manufacturers, he pointed out, have been compelled to supply 220 volt lamps at a given candle power and efficiency in the same size bulbs as are used for 110 volt lamps. With flashed carbons the manufacturers meet with great practical difficulty of properly disposing their long thin 220 volt filament in the same space as their shorter and thicker 110 volt filament, and therefore most of them solve this problem by resorting to a filament of much higher specific resistance than would be given by the flashing operation. The filaments of high voltage lamps largely used to-day are, on account of the omission of the flashing process, faster converters of energy into heat and light than flashed filaments of the same candle-power and efficiency, although the watts supplied to each be the same.

On comparing the behavior of such 220 volt lamps with that of 110 volt lamps, the roughest of tests shows that there is a far more rapid falling off of candle power during life with the former than the latter. At the same time the efficiency of an unflashed lamp decreases in a given number of hours by a far greater percentage than is the case with the flashed lamp. Mr. Robertson has made a series of life and efficiency tests on high-voltage lamps. They show that on the average unflashed 220 volt 16 candle power lamp the percentage loss of candle power in 600 hours is about 42 per cent., and the average drop of efficiency is about 35 per cent. The author further points out the disadvantages of the high specific resistance of filaments which have not been flashed, and that the occluded gases are retained in a far more persistent degree by high specific resistance filaments than the low specific resistance flashed filaments. As the same size of bulb has been retained for the 220 volt lamps as was used in the 110 volt lamps, it is impossible to give a greater separation between the leading-in wires of the lamp. This question is a vital one, and one which might prove very disastrous to the life of the lamp. Electrostatic effects also increase with the voltage and the "Edison effect" or leakage current which leads to short circuiting is also very marked during the manufacture of the high voltage lamp. Mr. Byng sums up the situation with the assertion that "with our present knowledge, the best form of 200 volt lamp is that which has a well flashed low specific resistance pure carbon filament in a large bulb, with a well insulated moisture proof cap allowing the poles to be placed at a reasonable distance apart. It should consist of a single filament, and be so disposed in the bulb that it can withstand the disturbing effects of gravity and electrostatic charges on the bulb."

Mr. Byng's propositions for the solution of the problem were not denied, but rather encouraged by those who participated in the discussion of this highly interesting and timely paper. The result of the discussion may be summed up as follows: At the present time the 220 volt lamp is not as efficient nor as durable as the 110 volt lamp, and in order that the consumer may keep down his bill for current he must spend money in more frequent renewals of his lamp. This is offset, however, by the fact that the introduction of high voltage will reduce the expenses of the generating station, which will, in turn, reduce the price of current. The reduction of first cost in laying the mains will also enable the stations to extend their territory and supply current economically to scattered districts and suburbs. The above, it must be borne in mind, are the results of English experience, which do not seem to be borne out fully on this side of the Atlantic where, according to the reports from manufacturers and consumers, the 220 volt lamp has found a ready and extensive market and is giving good satisfaction.

The General Electric Report.

WE print elsewhere a full abstract of the General Electric Company's report covering the year 1897. The striking feature of this report as compared with that of the previous year is the fact that the gross earnings were less by nearly $300,000 than those of the year previous, while the expenses were increased by more than $500,000. This showing is strong evidence of the fact that while the company may have been comparatively busy, the prices obtained must have been low. This view is borne out by the fact that in all departments at the company's works the sales show increases over previous years of business. Thus, in the lighting department there is an increase of nearly 6 per cent., in the power and mining department an increase of 60 per cent., in the railway department 33 per cent., and in the supply department we find increases varying all the way from 20 to 92 per cent. Even the sales of incandescent lamps showed an increase of 10 per cent.

One cannot but deplore the state of affairs existing in the electrical trade, as exemplified by this showing. It is probably true that prices have bettered slightly during the past few months, and that had the financial statement been drawn within the last thirty days the showing would have been a better one, but as it stands it indicates very strongly that some radical measures will have to be undertaken to put the company on a dividend earning basis. This of course has been realized some time ago, and that such action may shortly be looked for is very definitely foreshadowed in President Coffin's report, in which he points to the early reduction of the share capital of the company with a view to the resumption of dividends. We believe that such a course is a wise step and would react favorably on the entire industry. It needs hardly to be pointed out that, however carefully a non-dividend paying corporation may be managed, the very fact that no dividends are expected to be paid acts as a drawback in many ways; the converse of this proposition is self-evident.

It will be noted that the company places the value of its patents and franchises at $8,000,000; this figure, which has long been criticised, has perhaps less justification now than ever. The recent refusal of the Circuit Court of Appeals to sustain a preliminary injunction on the Vandepoele patent has still further shaken the ground on which that figure is based. But President Coffin seems to find some consolation in the fact that the business of the future will tend largely toward the third rail and the underground conduit, so that he anticipates that an adverse decision in the Vandepoele patent will have no marked effect on the business of the company. We sincerely hope with President Coffin that such may prove to be the case. But whatever criticisms may be brought against the company, there is no question of the fact that it has put its house in good order for business. Its factories are generally acknowledged to be in excellent condition, and although its stockholders may be yearning for dividends, no creditor is knocking at the door. What with the general revival of trade during the opening months of the present year and the heavy Government business entrusted to the company, it is more than probable that next year's balance sheet will show a decided improvement over that for 1897. Besides, the foreshadowed scaling down of the company's share capital will put it on a dividend paying basis, even on the present showing.

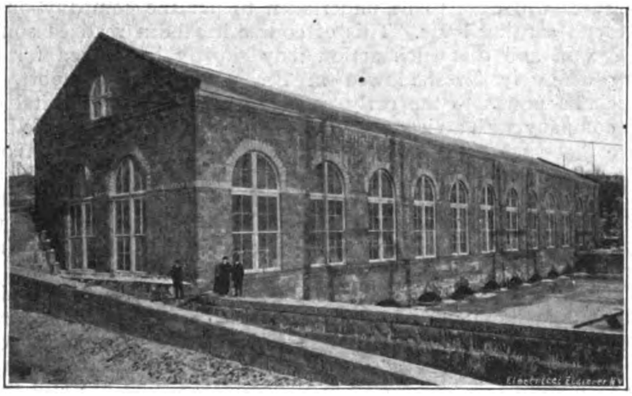
LEGAL NOTES

Decision in Favor of the Fischer Foundry and Machine Co.

The controversy between the Fischer Foundry and Machine Co., of Pittsburg, Pa., builders of the "Fischer" engine, and the Weston Engine Co., of Painted Post, N. Y., builders of the "Imperial" engine, regarding the infringement of certain patents relating to self-oiling engines, has been decided in favor of the Fischer Foundry and Machine Co. This decision, it is claimed, affects some other builders of self-oiling engines, and may result in a modification in the existing designs of this type of engine.

Electrical Utilization of the Falls of St. Anthony, Minneapolis, Minn.

IN our issue of June 2, 1897, we announced the completion of the extensive works on the Mississippi River at Minneapolis, Minn., by which a great part of the power of the lower Falls of St. Anthony is utilized. This undertaking marks an epoch in the history of the twin cities of the Northwest and brings into extensive use by means of electricity, another of the important waterfalls in this country. The article, referred to above, gave a detailed description of the hydraulic work at the Falls and a description of the power house and was accompanied by illustrations showing the dam at high water viewed from the west side of the Mississippi, a map of the St. Anthony Falls transmission plant, a view of the dam at low water showing the bear trap gates and a view of the power house during high water. Since the publication of that article, important additions have been made in the power house, and numerous substations have been constructed, the details of which will certainly prove of interest.



EXTERIOR OF POWER HOUSE, ST. ANTHONY FALLS, MINN.

HYDRAULIC EQUIPMENT IN POWER HOUSE.

Each hydraulic unit consists of four horizontal Victor turbine wheels, manufactured by the Stillwell-Bierce & Smith-Vaile Company, of Dayton, Ohio. Each wheel is 42 inches in diameter and runs at a speed of 130 revolutions, giving 250 h. p. They are erected in the turbine chambers, 4 wheels in each, giving a total power to each hydraulic unit of 1,000 h. p. The water passes separately into each flume through two head gates, each 8 feet wide and 9 feet high, operated by a hoisting attachment on the deck of the wheel chamber. Each set of four turbines discharges into a separate arched tail race tunnel the full width of the wheel chamber passing under the power house and discharging into the main tail race below. This tail race is 207 feet wide and 100 feet long. The bottom of the floor together with the foundations for carrying the masonry of the power house is made up of a solid bed of concrete 22 feet square and 2 feet thick. At the eastern side of the power house are two pairs of 21-inch horizontal wheels for the exciters, arranged for operation independent of the other machines, if necessary. These are from the works of the D. S. Morgan Wheel Company, Dayton, Ohio.

In the operation of all water turbines, the question of proper control is not the least important. The governor employed to control the flow of water to the wheels is the "B" type of Lombard governor, guaranteed to hold the normal speed of the wheels constant and the momentary fluctuations due to a large load to within 5 per cent. of normal under any conditions. It is belted to a small pulley on the generator shaft. It consists primarily of a governor directly controlled and a small hydraulic ram which controls the distribution to a second ram which in turn actuates a third ram acting directly on the gate closing mechanism.

THE DYNAMO ROOM.

The dynamo room of the power house is a long single chamber, finished in hard wood, with a gallery 10 feet wide running the entire length of the east wall. In this gallery are placed the switchboards, transformers, and instruments, together with the general offices, drafting rooms, etc. The main room is lighted by 15 windows, each 12 feet by 25 feet. The gallery is lighted by 10 windows, each 4 feet by 7 feet. An electric traveling crane runs the entire length of the dynamo room.

In the design and construction of this station provision has been made for a steam plant of equal capacity to that of the hydraulic plant. Opposite each generator will be erected a 1,000 h. p. engine which can be coupled to the dynamo for use in the event of scarcity of water or extreme frost. This will necessitate also the building of a boiler plant, but the installation of the steam plant has not yet been commenced. The ultimate capacity of the plant is 10,000 h. p. in ten units of 1,000 h. p. each.

The system of distribution contemplated is a combination of direct current for the service of the Minneapolis railroads in the vicinity of the power house, and of three-phase alternating current with converter substations for the out-lying districts and for the St. Paul roads. Five alternators and two direct current machines are now in position. Two alternators and one direct current machine are still to be erected.

THE GENERATORS.

The alternators are of the revolving armature type, having 36 poles and giving an output of 700 k. w. (1,000 h. p.) at 3,450 volts when running at the speed of the wheels, 130 revolutions per minute. The frequency is $34\frac{2}{3}$ cycles. Each alternator stands 10 feet 8 inches high on a base 12 feet 6 inches by 10 feet $10\frac{1}{2}$ inches. The armature shaft is extended 12 inches beyond the outer bearing to allow the engine coupling to be attached when the contemplated steam plant is installed. The poles, cast into the soft steel field ring are laminated, the laminations being insulated from each other by a heavy coating of Japan applied to each side of each lamination. The ring is ribbed to increase rigidity. The field winding is made upon shells, from which it is thoroughly insulated, and both poles and winding are arranged to allow of easy removal of the latter from the yoke without disturbing either armature or field structure. The base, also of cast steel, is constructed to allow of movement of the field frame parallel with the shaft. This method allows the armature to be inspected and in case of necessity repaired without unbolting and raising the upper part of the field ring. The bearings are made of extra length, are self-aligning, self-oiling and lined with babbitt.

The armature is of the slotted core or ironclad type, the laminations, dove-tailed into a spider to avoid the use of bolts through the core, being arranged to allow of radial ventilating ducts $\frac{3}{8}$ inch wide. The laminations are thoroughly insulated before the introduction of the coils, which are previously shaped on forms and are amply insulated. The internal diameter of the armature is 7 feet 6 inches. The peripheral speed is 3,140 feet per minute, and the air drawn in through the spider and passing through the ducts just mentioned, thus circulates throughout the core and thoroughly ventilates the armature. The collector rings are assembled on a separate spider, and are insulated from it by heavy moulded mica, and from each other by thick insulation discs. Connection between the rings and windings are arranged for ready disconnection if necessary. The test applied to the rings is of three times the running potential between them and the shell.

The weight of the armature complete is 25,000 pounds, of the entire machine 84,000 pounds.

The two direct current generators are standard eight-pole machines giving 700 k. w. when running at 130 revolutions per minute. The no load pressure is 575 volts, and the machines are over compounded to 600 volts. Each is coupled to the turbine shaft in manner similar to the alternators, and the shaft is also extended to receive the engine coupling.

These machines are standard General Electric railway generators, with the construction of which most of our readers are familiar. Briefly, the ribbed field ring is of cast steel as are the poles and field windings in the alternators. The spools are of malleable iron on which the series and shunt windings are placed in separate compartments, rendering each accessible with equal ease. The armature is ironclad, built up of Japanned laminae, dove-tailed to the spider and ventilated by radial 4-inch ducts.

The winding is of insulated copper bars laid in insulated slots. It is known as the "barrel" winding and gives the completed armature the form of a perfect cylinder. The commutator and shell are forced over an extension of the armature spider, obviating movement of the shell with respect to either spider or windings. The commutator bars are of hard drawn copper, insulated from each other by mica. A large number is used to give a very low voltage between segments, not exceeding 8.8 volts, when the machine is running at 630 volts. The brush ring is of the latest type, as are the brush holders. A hand wheel controls the movement of all the brushes, which are shifted, raised from or depressed upon the commutator simultawheel controls the movement of the brushes, which are shifted, raised from or depressed upon the commutator simultaneously.

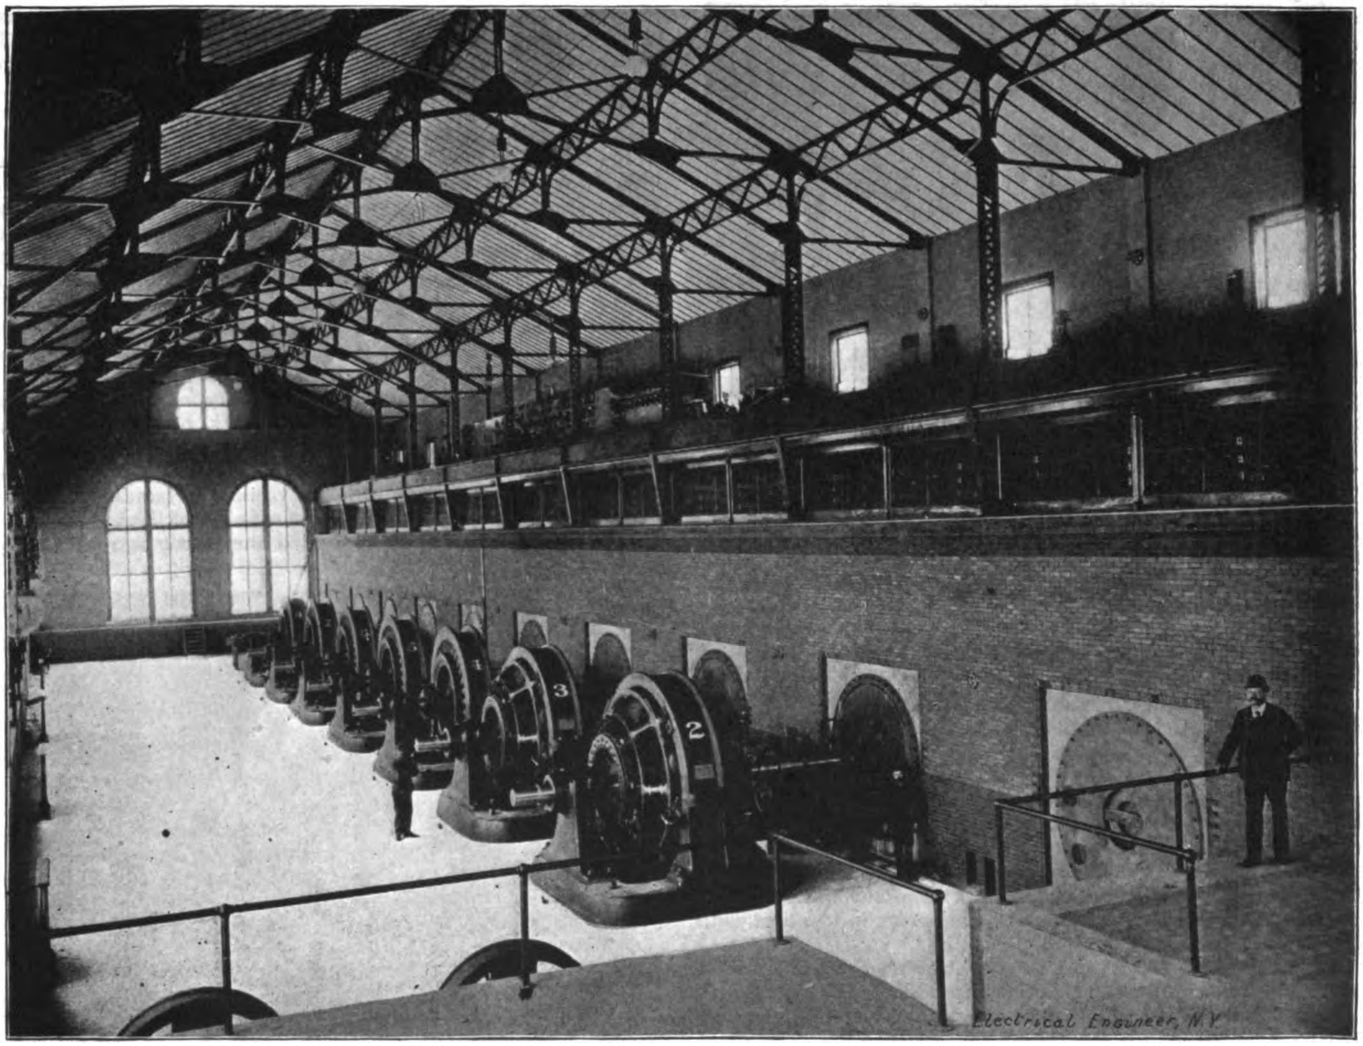
THE EXCITERS.

The exciters are six-pole, 100 k. w., direct current machines, directly coupled to the smaller wheels, and running at 280 revolutions per minute, supplying current at the same pressure as the main direct current generator. In all details of construction, they follow the larger direct current machines last mentioned. The diameter of the armature is 31½ inches, the peripheral speed 2,300 feet per minute, and the ventilating ducts ½ inch wide. The weight of the armature is 3,200 pounds.

The step-up and step-down transformers number twenty-one. Six step-up of 233 k. w. capacity and 15 step-down of 215 k. w., giving a total transformation capacity of 4,623 k. w. All are of the air blast type, and are built up of well tested iron laminations supported on and well insulated from, an iron frame, and divided into sections. Ducts running up through the sections allow of perfect ventilation by cool air forced through them, from underneath and controlled by means of shutters at the top. In general construction these transformers are similar to those built by the General Electric Company and used in the Niagara Falls-Buffalo transmission and the great transmissions of the West. The draft of air to cool the generating station transformers is furnished by a 60-inch blower driven by a four-pole direct current 600 volt motor direct connected to the fan shaft. It supplies 3 cubic feet of air per minute with one ounce pressure per kilowatt to the transformers, while the energy required to drive the motor is little more than one-tenth of one per cent. of the full load kilowatt capacity of the transformers. The efficiency of these transformers is about 98 per cent. They are designed for extremely close regulation varying only one per cent. from no load to full load. Before shipment each transformer was tested to 20,000 volts. Each weighs 4,500 pounds, stands 58 inches high on a base 38 inches by 32¾ inches.

SWITCHBOARDS.

The main switchboard is a handsome structure, occupying the gallery looking down upon the row of generators. It is of the standard G. E. panel type divided into alternator, railway generator and exciter sections—23 panels in all. The panels are of blue Vermont marble and all metal work on the front is highly polished.

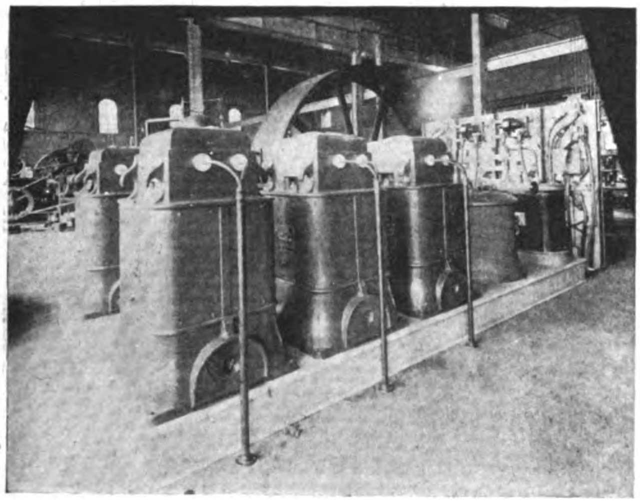


INTERIOR OF POWER HOUSE, ST. ANTHONY FALLS, MINNEAPOLIS, MINN.

The alternating switchboard consists of one panel for each alternator and five alternating current feeder panels. The arrangement of the bus-bars and switches on the latter allows any generator to be run separately to each feeder, or all in parallel, and to give two sets of independent bus-bars for convenience at moment of starting the rotary converters. The direct current switchboard consists of two generator panels, eight double feeder panels, and a station panel, the latter carrying a 700 volt voltmeter and 2,500 ampere G. E. station output

Thomson recording meter. The exciter board has two panels, one for each machine.

All the panels are set up in a continuous line, the alternating current panels at the west end of the board, the direct current panels at the east end. Extensive use is made on the alternating panels of the Thomson inclined coil type of instruments both ammeters and voltmeters. The alternating switches are of the new G. E. porcelain chamber plunger type. Each direct current generator panel carries a 1,500 ampere K circuit breaker and a 1,500 ampere illuminated dial Weston ammeter in addition to the other standard devices and each feeder panel has a 300 or 500 ampere circuit breaker and 200 ampere round dial ammeter.



NO. 1 SUB-STATION, TWO MILES FROM POWER HOUSE, ST. ANTHONY FALLS, MINN.

The exciter panels carry illuminated dial voltmeters and round dial ammeters.

ELECTRICAL DISTRIBUTION.

The direct current is fed from the switchboard directly into the main railway overhead system of Minneapolis, over lead covered cables, some running to the trolley line direct and others to a wire tower about 200 feet from the power house, from which the cables run to a pole line feeding the cars between Minneapolis and St. Paul. The system of distribution of the alternating current is more complex, and involves the use of three separate transformation and conversion plants, two in Minneapolis and one in St. Paul.

All are installed in the buildings containing the steam plants, shortly to be discarded entirely, of the Twin Cities Rapid Transit Company. Substation No. 1 is located near the center of Minneapolis, two miles from the power house. It contains six step-down transformers, two induction regulators, two alternating and two direct current switchboards and two 600 k. w. rotary converters. Substation No. 2 is located about four miles from the power house, and contains three transformers, and one converter. Substation No. 3 is in St. Paul and ten miles distant from the power house. Its equipment is identical with that of No. 1.

To substations No. 1 and 2, the current is transmitted at 3,450 volts over two triple conductor paper insulated lead covered cables, laid in cement lined iron conduits furnished by the National Underground Conduit and Cable Company. The manholes are placed as nearly as possible 500 ft. apart. It is taken from the switchboard first through a series of General Electric alternating current lightning arresters, similar in construction and operation to those so successfully used in the long distance transmissions of California, Utah, Colorado, Montana and elsewhere. From these it continues to the step-down transformers, in which the pressure is reduced to 387 volts. At this pressure it enters the converter switchboard and then passes to the alternating current side of the converters, issuing from the commutator side direct current at 600 volts. It then passes through another switchboard to the Minneapolis overhead wires.

To transmit the current to St. Paul involves the use of step-up transformers at the power house. The alternating current passes into these at the initial voltage of 3,450 volts and is raised to 12,000 volts, at which pressure it enters the transmission line, passing first through a bank of lightning arresters. The line consists of triple conductor, paper insulated lead covered cable, one cable only being used. At substation No. 3 the line is connected to step-down transformers. A similar transformation and conversion is effected as in the case of substations 1 and 2 and the current enters the main St. Paul direct current net work at normal working pressure.

The construction of the step-down transformers is similar to that of the raising transformers and they are cooled in the same manner. The blowers in the substations are 50 inches in diameter, and are directly connected to four-pole 550 volt motors. The amount of energy consumed in driving the motors is the same as in the case of the step-up transformers.

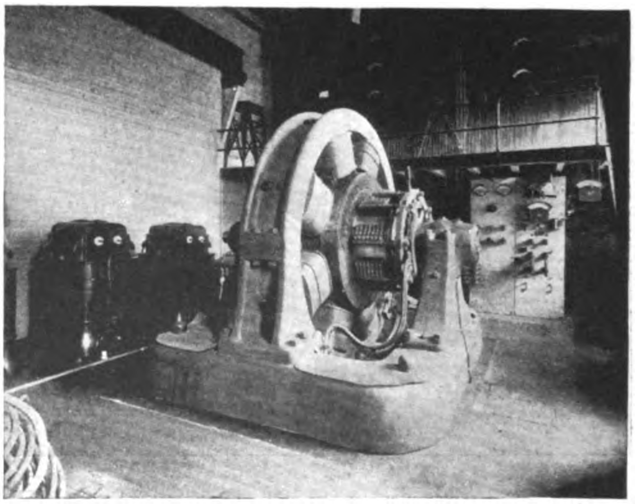
THE CONVERTERS.

The rotary converters are eight-pole machines of 600 k. w. capacity, running at 530 revolutions with a direct current voltage of 580 volts at all loads up to normal. The alternating current voltage is that of the secondaries of the step-down transformers—387 volts. The circular yoke of these machines is of cast steel, the inwardly projecting poles being of the highest grade steel. The poles and spools are arranged for easy removal from the yoke without disturbing either it or the armature or yoke. The spools are wound upon malleable iron shells and carefully insulated from them. The armature is of the ironclad type with ventilating ducts 5-16 inch wide.

The laminations, similar to those already described and similarly insulated, are mounted on a spider and the winding of the copper bars is insulated and laid in insulated slots. The interior diameter of the armature is 72 inches, giving a peripheral speed of 7,500 feet per minute. The commutator is assembled on a separate spider and a large number of segments used to bring the voltage between the segments, as low as possible. The collector is also assembled on a separate spider. In the construction of the bearings the same principles which govern the bearings of the large generators are employed, that is, they are self-oiling, self-aligning and of ample size. The lining is of hard babbitt metal.

The approximate weight of each rotary converter is 17,500 pounds for the revolving part and about 51,000 pounds for the complete machine.

Owing to the comparatively short distance between the generators and the rotaries, and the use of underground cable rather than an overhead line, artificial inductance has been introduced to secure the necessary flexibility in the direct current voltage



NO. 2 SUB-STATION, FOUR MILES FROM POWER HOUSE, ST. ANTHONY FALLS, MINN.

of the rotary. This inductance consists of a three phase open magnetic circuit inductance coil placed between the transformer and each rotary, and allows of a great range of adjustment in the direct current voltage. The coils are bundles of iron wire wound with a finely stranded cable. They are assembled in protecting cases and are cooled by a current of air taken from the blower which cools the transformers. These coils are also useful in preventing idle current from circulating between the two rotaries operated from the same transformer, should their field adjustment not be carefully made.

The switchboard in substations 1 and 2 consists of two alter-

nating and two direct current panels in each. In substation No. 2, one alternating and one direct current panel. These switchboards are of blue Vermont marble and in general construction resemble the switchboard in the generator station. The alternating current panel carries inclined coil instruments and single-pole quick break switches of 1,000 amperes. The continuous current panels are equipped with circuit breaker, illuminated dial voltmeter and the usual standard equipments.

In order to protect the rotaries in case of reversal of current, an automatic device is provided in each direct current panel. In case the current on the direct current side should be reversed a circuit breaker is automatically brought into action to break the circuit and protect the machine. The entire electrical equipment was installed by the General Electric Company. The aggregate weight of the electrical machinery is considerately over 1,000,000 pounds.

The president of the St. Anthony Falls Water Power Company is John J. Pillsbury, whose extensive interests in Minneapolis are well known; Wm. de la Barre is chief engineer, agent and treasurer, and Edward P. Burch, electrical engineer of the Twin Cities Rapid Transit Company has had charge of the electrical work. It will thus be seen that in bringing this plant to completion, the engineering forces of both companies have worked harmoniously together. Before beginning the work, data was obtained by personal visit to every electrical transmission plant of importance in the United States, and the result is one of the most perfect, and the most modern installation now in operation.

LETTERS TO THE EDITOR

Liquid Air.

IN the last issue of The Electrical Engineer Mr. W. H. Dickerson, in a letter to the editor, criticised certain portions of the writer's article on liquid air which appeared in The Electrical Engineer of April 14. He stated that the description of apparatus as well as the cost of producing liquid air, was wrong.

It is to be admitted that little is known regarding the details of Mr. Tripler's apparatus, since he has endeavored to keep this as secret as possible. The writer's description of this was gleaned from what Mr. Tripler so kindly allowed him to see at the laboratory, as well as from explanations made at that place some six weeks ago. The process, as explained in the article, is essentially correct. At the same time the statement was made that with the expenditure of forty horse power, the output of the station would be about forty gallons for a ten hour run. That is 10 h. p. per hour can produce about a gallon of liquid air, which was the statement made by the writer in the article. It is, of course, possible that the apparatus might have been materially changed during the last month, thus affecting the cost of production. The writer only endeavored to give a general description of what could be ascertained at the time.

In the article an account was given of Prof. Peckham's lecture, but no attempt was made to name the originators of each particular experiment, as this seemed unnecessary, since the experiments were drawn from all available sources. It was not the intention of the writer to detract any credit that is due to Mr. Tripler.

The writer's statement concerning the loss of heat which a jet of steam experiences in being converted into ice is so obvious to almost any one that it hardly needs explanation. If Mr. Dickerson will take the trouble to look up the subject in any book on elementary physics he will be convinced of the correctness of the figures, as well as of the terms.

Again, if Mr. Dickerson will look up some of the back numbers of "Nature," he will find that a glass receiver protected by a Crookes vaccuum was first applied to refrigerating work by M. Cailletet, of Paris, and was popularized, but not invented, by Dewar, as he would want us to believe from his letter. Such errors are of course "very unprofessional and distasteful to readers conversant with the facts," especially since "courtesy should demand that credit be given to the originators."

SOL. D. BENOLIEL.

Brooklyn, N. Y., April 28, 1898.

LITERATURE

MAGNETS AND ELECTRIC CURRENTS. By J. A. Fleming, M.A., D.Sc., F.R.S., London, 1898. E. & F. N. Spon. 408 pages. 5 x 7½ inches. Cloth. Price, $3.00.

This book may be considered as taking the place of a volume published by Prof. Fleming about twelve years ago entitled, "Short Lectures to Electrical Artisans," which was a reprint of a course of lectures given to the pupils and workmen at an electrical engineering factory. The information contained in that brilliant little volume has been thoroughly recast so as to conform more nearly to the present state of knowledge; and it is evident that the author has fulfilled his original aim of supplying electrical artisans and engineering students with a brief, thorough and elementary account of the scientific principles underlying modern applications of electricity in engineering. With this object in view the use of mathematical symbols has as far as possible been avoided, which at once enables the non-mathematical student to read the book intelligently and understand its contents.

Perhaps the most striking feature of the book and one which may be subject to some criticism and elicit discussion on this side of the Atlantic is the introduction of the new terms and phrases proposed by Mr. Heaviside and others, but which have not as yet been universally accepted. We refer to such words as gaussage and gaussivity, voltivity, fluxage, fluxivity, etc. Should these terms, however, be universally recognized in the near future, and we trust that they will be, their introduction into the text of this book will make the latter more valuable and up-to-date than any other similar publication.

The book is divided into ten chapters, which deal respectively with magnets and magnetism, measurement and units, magnetic force and magnetic flux, electric currents and electromotive force, the measurement of electric currents, electromagnetic induction, electromagnets, alternating currents, electric measuring instruments and the generation of electric currents. A striking feature of the book is the symbol $\frac{\text{E.}}{\text{C. R.}}$ imprinted on the cover, the use of which will not seem apparent until the reader receives the following instructions on page 133: "Cover over with the finger any letter, say C (current) and the position of the remaining letters $\frac{\text{E}}{\text{R.}}$ denote that the numerical value of the current is equal to that of the e. m. f. divided by that of the resistance. In the same way it is seen that the e. m. f. (E) is equal to the product C R of current and resistance."

NEWS AND NOTES

A Substitute for Platinum in Incandescent Lamps.

According to a German contemporary, experiments with iron-nickel alloys have shown that different co-efficients of expansion are obtained according to the percentages of the two metals. An alloy containing 45 per cent. of nickel has the same co-efficient of expansion as platinum, and it is stated that this has been confirmed by experiments made at the Reichsanstalt. It is proposed to use this alloy to replace platinum in the manufacture of incandescent lamps. An interesting paper read before the Société Internationale des Electriciens by M. C. E. Guillaume, has described recent experiments on the expansion and magnetic properties of steel-nickel alloys.

"Maritime Electrical Association" for Canada.

A well attended meeting for the organization of a Maritime Electrical Association was held at the Halifax Hotel, Halifax, N. S., on the 12th inst. A large number of gentlemen were present and were unanimous in their support of and sympathy with the movement. A constitution was adopted and the fol-

lowing officers were elected: President, F. A. Bowman, superintendent New Glasgow Electric Co., New Glasgow, N. S.; Vice-President, H. Colpitt, City Electrician, Halifax, N. S.; Secretary-Treasury, J. H. Winfield, Nova Scotia Telephone Co., New Glasgow, N. S. A representative executive committee was also elected. It was decided to hold the first regular convention at Halifax some time in September. The association starts out with a good membership list, and it is confidently expected that good work will be done in bringing together all those engaged in the electrical business for mutual exchange of ideas.

JOSEF HOFFMAN, the brilliant young pianist, is said to be passionately devoted to mechanics and electricity. He has invented various forms of telephones and electric lights, as well as batteries and other appliances.

Opening Exercises of the Electrical Exhibition.

TO say that Madison Square Garden was packed on Monday night would be using a mild term. Fully 10,000 people swayed and surged on the main floor and in the galleries, attracted by what proved to be one of the most interesting exercises ever held in connection with the opening of an exhibition. It was almost 9 o'clock when Chancellor McCracken, of the New York University, opened the exercises by an invocation.

Dr. Chauncey M. Depew was then introduced as orator of the evening and, needless to say, his appearance was the signal for prolonged cheering. Dr. Depew delivered one of his characteristic patriotic addresses, for which he had abundant material to work upon, considering the events of the previous forty-eight hours. He referred, among other things, to Franklin who, as he said, was never astonished at anything, whom no combination of circumstances could phase, whose sangfroid never left him, even in the presence of royalty. Yet, with all that, Dr. Depew ventured to suggest that if Benjamin Franklin could have been present there on that evening he would have been astonished. Again, Dr. Depew alluded to the glorious victory obtained by Commodore Dewey at Manila, and pointed out that it was to the cultivation of science in America that such results were made possible. Had Spain shown equal love for science and its industrial applications, no conflict between that country and this would probably ever have occurred. Science made liberty, and when Dr. Depew waved the American and English flags in either hand and called for three cheers for the combined English speaking nations of the world, who have always stood for light and liberty, the enthusiasm was unbounded and the cheering deafening. Many passages throughout Dr. Depew's speech gave rise to patriotic outbursts.

Dr. Depew then read the following message from President McKinley, sent from the White House at Washington by means of the same golden key used by President Cleveland, to open the Chicago World's Fair in 1893.

OPENING TELEGRAM FROM PRESIDENT M'KINLEY.

"It gives me great pleasure to open the Electrical Exhibition in Greater New York, and to participate in this wonderful demonstration of the latest method of recording and publishing by means of electricity. I congratulate you upon the achievements of American genius. I am glad to know that the resources of the wonderful electrical arts have already been so far advanced in the United States, that American electrical goods are welcome the world over."

The message came over the wires of the Postal Telegraph Cable Company, the golden Victor key being loaned for the occasion by Gen. E. S. Greeley. The message from the President declaring the Exhibition open was greeted with prolonged cheering; indeed, every mention of the President's name was a signal for general acclamation.

Following the reading of the telegram from the President, Vice-President Hobart sent the following telephonic message from Washington, which was received on the platform at the Exhibition and recorded directly from the receiver on to the recording cylinder of an Edison phonograph.

TELEPHONE MESSAGE FROM VICE-PRESIDENT HOBART.

"I respond with pleasure to the invitation of the New York Electrical Society to assist in opening the Electrical Exhibition held under its auspices at Madison Square Garden, and beg to express my wishes for its success as a means of promoting further advances in the great electrical and engineering arts with which our national fame is already so proudly associated. I congratulate the citizens of the Greater New York that they have this opportunity of studying all that is latest and best in the science to which Franklin, even in the midst of patriotic duties and cares, gave his transcendent genius."

The message came over the lines of the American Telegraph and Telephone Co. (Long Distance Co.), and the New York Telephone Co., and the phonograph was kindly loaned for the occasion by the National Phonograph Co., of Orange, N. J.

A unique performance, illustrating the rapidity with which news is now gathered and disseminated, followed the reception of the messages of the President and Vice-President. As soon as received both of the messages were set up in type on Linotype typesetting machines, loaned by the Mergenthaler Linotype Co., driven by a Lundell motor, loaned by the Sprague Electric Co. As soon as the type was cast it was made up in forms and printed on a platen press, loaned by the John Thomson Press Co., and operated by a Bullock electric motor. From the press the printed sheets were cut by a paper cutter run by a Crocker-Wheeler motor. It took but a few minutes to complete all these operations, and before Dr. Depew had closed his remarks the messages printed on Postal Telegraph Co. blanks were distributed among the audience.

The close of the exercises was signalized by Dr. Depew firing a Cuban dynamite gun, loaned for the occasion by the Sims-Dudley Defence Co., of New York. The feature of the firing of this gun, however, lay in the fact that the fuse was exploded by closing a contact through the medium of the Clark wireless telegraph apparatus. Of course the regular charge of dynamite was not used on this occasion, and for obvious reasons. Finally, Dr. Depew illustrated the method of blowing up vessels by means of submarine mines by pushing down a plunger on the platform, which closed a circuit that exploded a little torpedo in a large tank in the centre of the hall, in which a miniature battleship had been placed. Great havoc was caused by the scattering of water among the ladies surrounding the tank, and loud demands for heavy indemnity were heard on all sides, with talk of forcible intervention. This feature was installed under the supervision of Mayor Smith, of Pompton, N. J. The last feature of th programm was th singing of the "Star Spangled Banner" by Miss Hilke, contralto of St. Patrick's Cathedral, to the accompaniment of Conterno's band, and a splendid ladies' quartet of four cornets, the audience joining in tne singing. The platform was patroled and guarded by the Rugby Cadets in uniform.

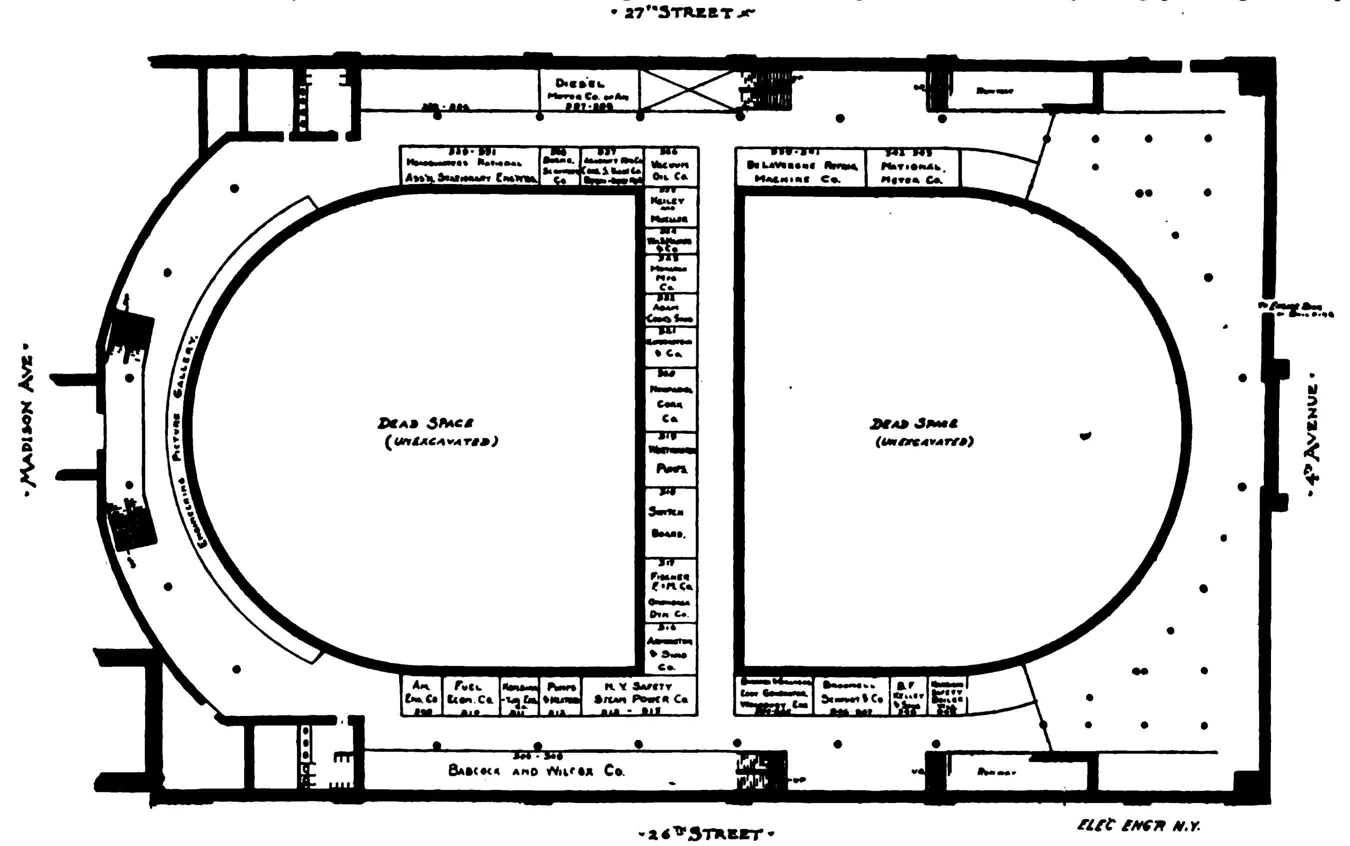
Everybody electrical within fifty miles of New York was present, and many were the expressions of delight at the eminently successful opening of the exhibition. Considering the usual delays accompanying every exhibition at the start, the present condition of the show is little short of marvelous. There were probably not a dozen booths in the entire building which were not in full running order, and by the time this issue reaches our readers the exhibition will be in full swing.

BORNE, SCRYMSER COMPANY, New York, have a number of competent representatives at the Show who are indefatigable in their efforts to extol the merits of their company's oils and the uses to which they are put in electric light plants, both central station and isolated.

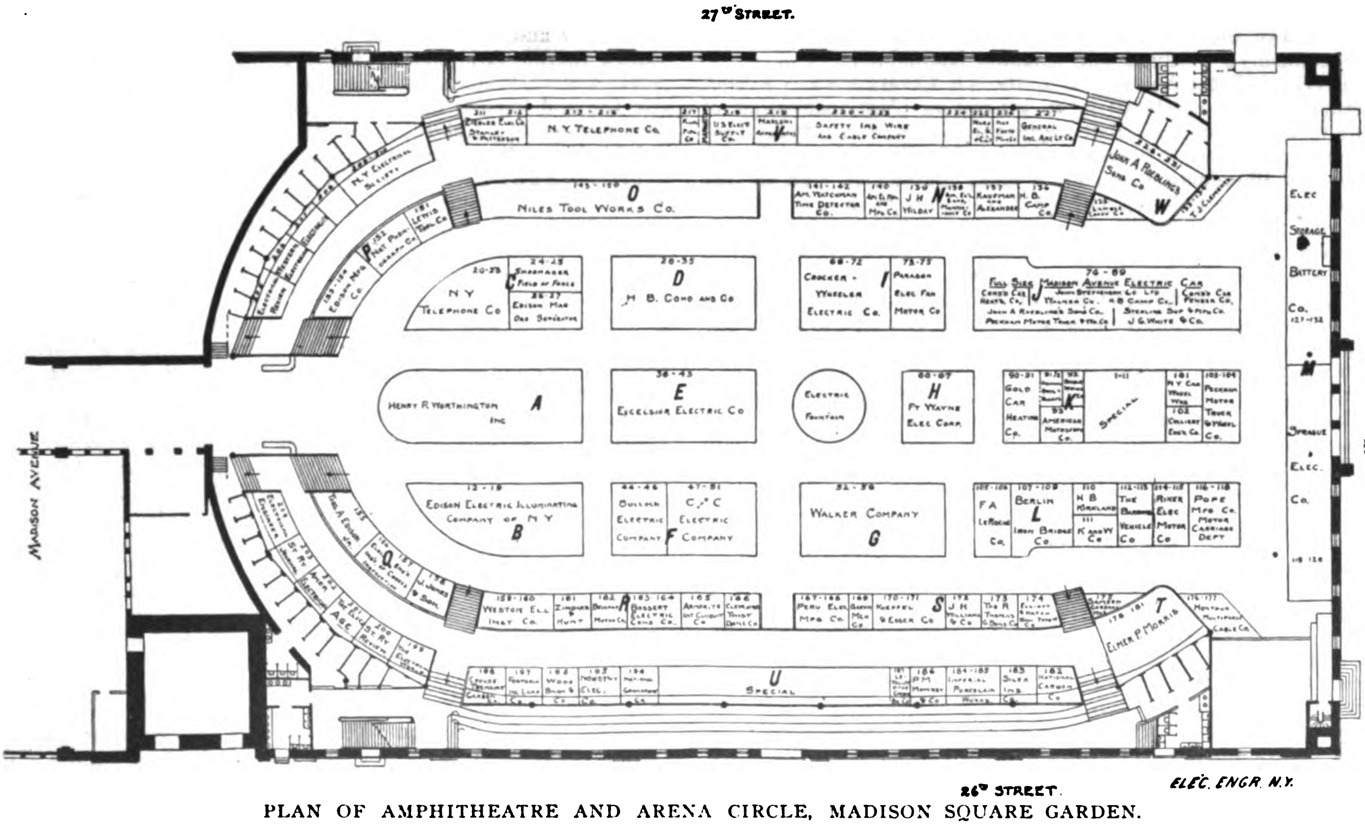
THE EXHIBIT OF THE GARVIN MACHINE COMPANY, New York, is rather limited, owing to the large amount of space that would be needed to exhibit any of their standard lines of milling machines, lathes, planers, shapers, drill presses, grinders, gear cutters, cutter grinders, wire spring coilers, profilers, etc. However, they have gotten together a very interesting exhibit, consisting of a very ingenious and improved twist drill grinder, as well as several small tools. These are supplemented by circulars of their large line of tools which are carried in stock at their store.

The Exhibits at the Electrical Exhibition, Madison Square Garden.

We give herewith plans which show very clearly the location of the exhibits at the Garden, save such as have been arranged for since the plans were prepared, or cannot be placed until after the opening exercises on Monday night, on account of the space requirements for that occasion. Among the latter exhibits are those pertaining to the Amateur model making competition, the personal exhibit of Prof. Short, the apparatus from the Brooklyn Polytechnic, etc., all of which is intended to go in the Arena Circle space marked special. In the basement plan, at the Madison avenue end, the Engineering Picture Gallery is a new feature of great interest, already being put in good shape.



PLAN OF BASEMENT, OPERATIVE EXHIBITS, MADISON SQUARE GARDEN.



PLAN OF AMPHITHEATRE AND ARENA CIRCLE, MADISON SQUARE GARDEN.

In addition to what is shown in these two large plans, there are the exhibits in the Concert Hall and the Assembly Room. These include the eight superb, historical wax tableaux, the Parsell exhibit of electro-deposition work, the third rail model, and the

beautiful Moore chapel, a complete church capable of holding about 100 people nearly all seated, and lit entirely by vaccum tubes. There are also other features of interest in the Concert Hall, for lecture work, etc., and in the Main Hall. Reference to these will be made later.

Exhibit Notes.

OTIS BROTHERS & COMPANY show one of the most interesting electrical appliances in the Exhibition, consisting of a model of their house elevator operated by push button device. This elevator embodies many admirable features which increase the safety and efficiency of the apparatus. In addition to this they exhibit one of their standard electric engines in operation, of which there are some 1,700 in use in this country and in Europe; they also exhibit in connection with the Excelsior Electric Co., of Brooklyn, one of their standard eelectric elevators operated by one Churchward's transformers.

THE CROCKER-WHEELER ELECTRIC COMPANY. It is yet too early to attempt any full description of this company's extensive exhibit, but what it will be like when in full running order can be gathered from the following list of apparatus shown: 150 k. w. direct connected generator, without engine; ½-100 direct motor; 80 k. w. belted generator; 35 h. p. motor; 25 h. p. motor; 15, 10, 3 and 1 h. p. motor. "Size 3" motor-dynamo; "size 5" dynamotor; "size 1" dynamotor; "size ¼" dynamotor. And finally a 10 h. p. mill motor with controller and resistance. The exhibit thus covers a wide range of motor work and will without doubt attract the attention it deserves.

THE C. H. BARROWS COMPANY, of New York, draw large crowds who are attracted by the unique Barrows 3-wheeled motor vehicles, driven by storage batteries. Two of these vehicles are shown. The No. 0 weighs 650 pounds and has a running capacity of 20 miles on one charge. The No. 2 weighs 1,250 pounds and is capable of running 40 miles on one charge.

THE ARMINGTON & SIMS COMPANY exhibit one of their 13 x 12 "1898 Pattern" engines, direct connected to a 50 k. w. Walker generator. The special points of merit in this engine will not fail to attract the attention of visitors.

THE EXHIBIT of the Albany Lubricating Compound and Cup Company is devoted to extolling the merits of the Albany grease and grease cups, for lubricating purposes. All power users, large and small, will find it worth their while to examine the company's products and splendid testimonials.

THE AMERICAN BALL ENGINE COMPANY'S exhibit comprises a complete 25 k. w. generating plant, consisting of one of their American Ball engines and a 25 k. w. direct connected generator. The current from this plant is used for an overhead illumination and for a large illuminated sign on the side wall of the building and for driving one of their multipolar motors, thus illustrating a complete electrical plant of their own manufacture covering the generating of electrical current and its application for both light and power.

BURHORN & GRANGER, of New York, have on view and in operation one of their 9 x 12 inch Woodbury automatic high speed, improved engines, direct connected to a 25 k. w. Eddy generator. This engine is to be set on the present floor without any foundation whatever, to show its perfect running balance, and also to demonstrate with varying loads, etc., by a sensitive recording tachometer that the Woodbury engine with a Shepherd governor regulates within one-half of one per cent. under all conditions in which there is sufficient steam to carry the load. They also show the automatic oiling system and method of valve construction, etc., which enable visitors to understand thoroughly the excellent features of the Woodbury engine.

THE NATIONAL CARBON COMPANY exhibit a complete line of their carbon products, which illustrate strikingly the degree to which carbon enters as a factor in the electric arts. Of course, their large variety of solid and cored carbons for all classes of arc lighting are a prominent feature of the exhibit. But besides these there is a large variety of other products of not less interest and importance. Thus there are to be seen the National and Klondike porous cup cells; special gas engine cells and cylinder cells of various sizes; Fuller type and gravity cells. Among the carbon specialties we note back plates, diaphragms, granular and globular carbon, lightning arrester plates, carbon boxes, strips and tubes; filament blocks; carbon brushes, etc. The whole presents a striking array of products.

THE CROWN WOVEN WIRE BRUSH COMPANY, of Salem, Mass., have a small but neat exhibit, consisting of a show case, containing sample brushes, with circulars, etc. There is also a framed exhibit of woven wire dynamo brushes.

SAMSON CORDAGE WORKS have a show case near one of the main flights of stairs at the Exhibition, containing big sample coils of "Samson Spot" arc lamp cord, trolley cord, bell cords, couplings, etc. These are of considerable interest to visitors at the Exhibition, as some trouble has been caused by using poor qualities of cord for these purposes, and much better results are shown by using their special waterproof finish.

THE CLEVELAND TWIST DRILL COMPANY have on exhibition their entire line of products. These are contained in a show case about 4 feet square by 9 feet high filled with samples of drills, reamers, electricians' combination bit and fishing tool. They also show a full line of their new taper shank oil tube drills and oil feeding sockets, both of which have just been placed on the market and which are meeting with universal favor.

THE AMERICAN ELECTRICAL NOVELTY AND MANUFACTURING COMPANY, of New York, show a variety of their specialties. Besides their standard line of dry batteries, etc., there is shown their latest novelty, the "Ever Ready" electric bicycle lamp. This consists of a neat case with lamp and reflector, and containing three dry cells. These are capable of giving full illumination of the lamp for from six to eight hours if used for one or one and a half hours at a time. After that period they can readily be removed and replaced by a fresh set of cells. No screws or binding posts are used, the mere act of putting the cells in place, effecting the desired connections. The absence of oil, wick, liquids, wires, etc., will make this little lamp outfit a subject of general interest to all bicyclists at the Show.

THE MONTAUK MULTIPHASE CABLE COMPANY'S booth is located at the north-eastern section of the Garden at the junction of the outer aisle, parallel with 27th street, and the outer aisle parallel with Fourth avenue, among their neighbors being the Electrical Storage Battery Company, Sprague Electric Company, the Peckham Company the Riker, the Pope Companies, etc. The exhibit is similar to that in their office at 100 Broadway. As our readers are aware, the Montauk Multiphase Cable Company have recently placed upon the market a new and revolutionary line of electrical goods—in other words, thermostatic electric cables to be used for all electrical interior work—such as electric bells, electric gas lighting, electric fire and burglar alarm, telephone and telegraph work, and even for electric lighting. We will have more to say of this exhibit in a subsequent issue when things are ship shape.

THE KEYSTONE ELECTRICAL INSTRUMENT COMPANY are exhibiting a full line of instruments at the Exhibition. Among the features is a slate switchboard on which are mounted a type "K" illuminated dial and a pair of type "R" instruments. In addition to the above there are shown one of their potential indicators, an arc light voltmeter and ground detector and a ground detector for constant potential circuits. An excellent show is made by the company's line of portable instruments, represented by portable voltmeters for direct current only, and portable voltmeters for use on direct and alternating current. Besides this, they show a pair of their type "R" instruments in practical operation on a switchboard which will be used in connection with a dynamo and motor exhibition. The exhibit is in charge of Mr. Elmer P. Morris and Mr. J. F. Stevens, president of the company, is also in evidence frequently.

F. A. LaROCHE & COMPANY, New York, have brought together a representative exhibit consisting of a full line of their well known alternating current dynamos and central station equipment. Also a number of commercial switchboards for lighting installations. One of the main features of the display is a set of their new automatic independent circuit breakers. These latter are quite a novelty. All sizes of them are in action, which is accomplished by a direct current motor generator having a capacity of 5,000 amperes, which will keep the various sized circuit breakers in constant operation. The exhibit also contains the LaRoche system of arc lighting, converters, step-up and step-down; also some of their arc lamps of antique design. The exhibit also contains a full line of copper switches, and the LaRoche automatic quick break switches, a decided novelty in the switch line. Besides these there are shown a number of new automatic self-locking switches, which are now extensively used in big work in New York City.

J. P. WILLIAMS, general agent for the Paragon Ironclad Electric Motor, 39-41 Cortlandt street, New York, has constructed a pyramid of fan motors, 100 in number, all running, power motors up to 1 h. p. and all styles of ceiling and wall fans, as well as unique novelties in the electrical line.

THE CARD ELECTRIC COMPANY, of Mansfield, O., have in operation a 25 h. p. "S" type 110 volt motor; a 3 h. p. "E" type 110 volt motor; and a 12½ k. w. "E" type 112 volt dynamo. These machines are equipped with the necessary apparatus for successful operation, consisting of the Card automatic safety and limit switch for the motors and field regulating rheostat for the dynamo. The exhibit is under the management of the company's Eastern office in charge of the genial Mr. Elmer P. Morris, New York City.

ELMER P. MORRIS is representing a host of well known companies, including the following: Card Electric Company, dynamos and motors; Keystone Electrical Instrument Co., Kosmic Oil Filter Co., Highland Electrical Chemical Co., Soldering paste; Garton-Daniels Electric Co., lightning arresters; Simonds Mfg. Co., gears and pinions; Pittsburg Steel Trolley Pole Co., trolley poles. Besides these Mr. Morris exhibits electric railway supplies, iron and wooden poles, protected rail bonds, and car couplings. Mr. Phipps, of the Adams-Bagnall Electric Co., will assist in looking out for their interests and Mr. J. M. Holloway, of the Warren Electric and Specialty Co., will see to the display of Warren incandescent lamps.

THE WARD LEONARD ELECTRIC COMPANY are exhibiting various styles of their automatic magnetic circuit breakers in sizes from a few amperes up to the 2,000 amperes size. They also exhibit a variety of styles of automatic rheostats. A specially interesting feature of their exhibit is a new type of underload and overload rheostat which is known as the "SK" type, and which has many novel and valuable features. The compact size and simplicity of this automatic and its reliability in action will command general attention among the visitors in the trade. The Ward Leonard Company also exhibit various forms of the well known Carpenter enamel field rheostats, also a large variety of the porcelain lined outlet boxes, and switch boxes, etc., which have become standard for recent high grade wiring installations in New York City. A novel and very neat style of rheostat for small ventilating fans will attract a great deal of attention on account of its compactness and cheapness.

THE MANHATTAN ELECTRIC STORAGE BATTERY COMPANY exhibit a striking novelty in the shape of their "Liberty Electric Lamp." This is an electric night light, containing a small clock in the base of a miniature statue of Liberty. Inside of the base is a chloride accumulator having a capacity of from 5 to 6 ampere hours. By a turn of a knurled ring the light can be turned on at any hour of the night when required. This handy little beacon does away with the burning of a small gas flame all night. The reflector is so adjusted that it can be turned in any direction, also to throw the light down on the clock. The little stand is an ornament as well, and can be used for a banquet lamp by removing the reflector. Using it judiciously the battery will last a month on a single charge. An extra battery is furnished with each outfit. The lamp is an exact model of the Statue of Liberty and is made in the latest shades, green and gold, brown and gold, all bronze, all gold. Mr. B. B. Hoffmann is in charge of this exhibit.

THE AMERICAN MUTOSCOPE COMPANY have an exhibit of mutoscopes, showing moving pictures of scientific, comic and war subjects. Among these are a steam shovel, horseless carriage, etc. Some of the new war subjects of interest are as follows: "The Wreck of the Maine," which is a panoramic view of the wreck, showing the divers at work on the sunken vessel; "General Lee," leaving the Hotel Inglaterra, Havana, Cuba; "Captain Sigsbee," the Captain of the ill-fated "Maine" is shown descending the steps at the Capitol in Washington; the "Dupont," torpedo boat; "Maine" and "Iowa," battleships in Brooklyn Navy Yard; "Vizcaya," Spanish Cruiser, and many other interesting subjects are exhibited. Among the scientific subjects there is the "Ten-Inch Gun" at Sandy Hook. This immense gun, weighing 67,000 pounds, is seen to rise in the air, discharge its projectile and sink behind the fortifications. At the moment of the explosion, "the cone of vapor" is shown that follows the projectile out of the muzzle, about which there has been so much dispute in ordnance circles. The marks of the rifling are shown clearly in the smoke. The American Mutoscope Company will change the subjects daily, thus enabling daily patrons to see all views of interest to date.

THE FUEL ECONOMIZER COMPANY, of Matteawan, N. Y., show a complete economizer of suitable size for 150 h. p. boiler, erected with sectional asbestos covers and scrapers for removing the soot, running as in actual service. Also sections of headers and pipes showing various methods of making joints, and working model with blue prints and lithographs of installations in several prominent power houses in New York and vicinity. The exhibition is in charge of Mr. Wm. Downs, M. E., the company's New York representative; Mr. A. H. Blackburn, general manager; and Mr. P. J. Challen, from the works, is also in attendance.

HARRISON SAFETY BOILER WORKS.—This company's working exhibit consists of a 300 h. p. standard Cochrane feed water heater and purifier, complete with usual fittings, and a 7-inch horizontal Cochrane steam separator, new high pressure pattern, complete with companion flanges, gauge glass and fittings and drip valve. These are used in connection with the exhibition steam equipment.

The company's floor exhibit consists of a 350 h. p. Cochrane feed water heater and purifier, having the new style of cleaning doors and removable trays. The back plate of the heater is removed to show the interior construction, the manner in which the steam and water are brought together; the arrangement for controlling the cold water supply; the over-flow connection; the vented hood to protect the pump suction opening; and the provision made for carrying a large body of filtering material, such as coke, the blow-off opening, etc.

Here is also shown a 6-inch horizontal Cochrane steam separator, new high pressure pattern, complete with companion flanges, gauge glass and fittings and drip valve; and finally a 6-inch vertical Cochrane steam separator, complete.

ASHCROFT MANUFACTURING COMPANY.—This company's exhibit is included in that of their New York agents, Messrs. Manning, Maxwell & Moore. It consists of a full line of pressure and vacuum gauges, farm engine gauges, with new auxiliary spring attachment, locomotive gauges, locomotive double spring gauges, compound pressure and vacuum gauges, combination water pressure gauges, ammonia gauges, altitude gauges, test gauges, Westinghouse air brake gauges. Besides these are the company's locomotive and marine clocks, square and round revolution counters, screw test pump and gauge, inspectors' test pump and gauge, gas fitters' proving pump, Edson recording gauges, Kayser automatic safety water gauge, Ashcroft malleable iron pipe stocks, with solid dies, genuine Packer sleeve and boiler ratchets, Moscrop speed recorder, Tabor indicators for steam engines and gas engines, and the Coffin averaging instrument.

The boilers supplying the steam for the Exhibition are fitted with Ashcroft steam gauges. These goods are shown in a very attractive manner, in section and in all sizes.

THE MONARCH MANUFACTURING COMPANY have one of the most interesting exhibits to be seen in the entire Exposition, consisting of various applications of the Monarch engine stops and speed limits. One pair of these apparatus is mounted upon a table in connection with an engine throttle valve. The engine stop is connected so that by pressing any of the several buttons placed at convenient points, the valve is closed inside of five seconds. In order to make this demonstration very plain to visitors a church organ pipe is mounted on top of the valve, while below, the valve is connected with piping to a Sturtevant blower operated by an electric motor. One can readily see by this arrangement that when the fan is running and the engine stop valve is open, a note is sounded from the organ pipe, but the moment the valve is closed, this sound ceases, thus illustrating the effectiveness of the apparatus in a striking manner. The Monarch speed limit is operated direct from a second electric motor, the speed of which is controlled by a rheostat. A tachometer is also connected with the speed limit, so that the exact speed of the apparatus can be read off by the visitors. When running at a certain predetermined speed the speed limit has no effect upon the engine throttle valve, but the moment this limit of speed is exceeded—which is accomplished by moving the lever on the rheostat—the organ pipe is silenced in precisely the same way it would be, were any of the several buttons pushed. This makes a very interesting exhibit for steam engine users and the working of the apparatus is so easily shown to them that they can see and appreciate in a moment just what the Monarch can accomplish. The exhibit is under the management of Mr. Albert A. Cary, the company's business manager.

THE ELECTRIC VEHICLE COMPANY will have one of their new electric hansoms on exhibition as soon as completed, which will be about the 10th of the month. They are also making preparations for electric cab service for patrons of the Exposition.

THE NEW BRITAIN MACHINE COMPANY are making their exhibit of Case engines in connection with those of the Sprague Electric Company and the C & C Electric Company. The first engine, their 5D size 25 h. p. at 550 r. p. m., will be connected direct with the Lundell generator, probably of 15 k. w. capacity. The second, their No. 4 engine, 8 h. p. at 650 turns, connected to a C & C generator of 5 k. w.

THE DIESEL MOTOR CO. OF AMERICA exhibit the first Diesel Motor ever shown in this country. It is 20 h. p., the actual brake power, and will be run on petroleum. It is shown here only for exhibition purposes, as there will be no time and room for tests as to its economy under variable loads. These will be made after the close of the exhibition in a location already chosen for the motor, near their office in this city.

THE CONSOLIDATED SAFETY VALVE COMPANY, included in the exhibit of Manning, Maxwell & Moore, embraces the well known Richardson-Ashcroft solid nickel-seated pop safety valve; Consolidated brass-seated pop safety valve; Richardson-Ashcroft Board of Trade marine valve; Consolidated encased locomotive pop safety valve; Consolidated encased locomotive pop safety valve, with muffler attached; Consolidated portable farm engine, hoisting engine, steam fire engine, and steam launch pop safety valve; Consolidated side outlet pop safety valve; Blacknall patent relief valve for locomotives; Richardson patent shifting valve; and the Richardson patent water relief valve.

The boilers supplying the steam for the Exhibition are fitted with Consolidated safety valves. These goods are shown in a very attractive manner, in section and in all sizes.

SPRAGUE ELECTRIC COMPANY.—It would take a good deal of space to describe in detail this company's exhibit, and in this short preliminary notice we can give only brief mention of the nature and variety of the exhibits displayed within the Sprague Company's space. There is one direct connected lighting plant with a Case engine, six-pole generator, 25 h. p. frame; special Lundell power motors in size from ¼ to 10 h. p.; six-pole Lundell motors of 15 and 40 h. p.; 18 and 60-inch exhaust fan outfits with spherical motors, in operation; printing press in operation with Lundell slow speed direct connected motor; an organ with Lundell blowing outfit. This is in operation and played regularly by an organist.

An interesting exhibit is an automobile motor of the London cab type with Lundell controller, in operation. A Quimby screw pump, ½ h. p., operated by a medium speed Lundell motor; a dental outfit operated with high speed Lundell motor. Then there is a complete line of Lundell ceiling fans, electrolier and column fans, all in operation; one 40 h. p. armature with form wound conductors in 148 sections; a 2 h. p. London cab double wound armature complete. Of course, a general display of interior conduit is not wanting.

The exhibit of Sprague electric elevators shows an automatic house elevator machine with five "up" and "down" buttons, operating a dummy door, lock and switch. A tandem worm gear machine with No. 4 control, in operation; a machine of the company's London type without control. This machine has two tandem worm gears and two motors arranged on opposite sides of the drum, driving the drum in parallel; a dumb waiter machine with independent floor control, in operation; a screw machine passenger elevator with No. 2 control, in operation; a multiple sheave and ball nut machine, single decker, duplicates of which are in the Astoria Hotel. A Sprague No. 2 safety device of the wedge type, the type that is now being put on all Sprague machines. In addition to the machine exhibits, will be shown photographs of all machines, and various views of the Sprague factory.

The total floor space of the Sprague exhibit is 12 x 65 feet. The exhibit is at the East end of the Garden, and may be easily identified by a 51 foot electric sign which is constantly displayed.

It is rather difficult to pick out one feature more attractive than another, but it is quite possible that the Sprague London elevator machine (the largest elevator machine ever constructed) and the automatic house elevator, in addition to the organ in operation, will attract a great deal of attention.

RIKER ELECTRIC MOTOR COMPANY, are exhibiting electric vehicles, electric motors for vehicles and special electrical apparatus.

J. H. WILLIAMS & COMPANY'S display is one of the standard and special drop forgings particularly or incidentally adapted to the electrical industries.

THE HAYDEN & DERBY MANUFACTURING COMPANY'S exhibit, under the ægis of Manning, Maxwell & Moore, the following apparatus: Metropolitan automatic injectors; Metropolitan double tube injectors; H-D Srivewell ejectors; H-D patent suction strainers; H-D noiseless water heaters.

The above goods manufactured by this company are shown by samples of all sizes and with sections showing interior views of each.

The boilers supplying steam for the Exhibition are supplied with water by a No. 14½ Metropolitan double tube injector, which is the same type of injector that supplied the boilers for the last Electrical Exhibition, held in 1896.

THE BECKMAN SYSTEM of automatic control undergrate mechanical draft is exhibited by the Kensington Engine Works, Limited, Philadelphia, Pa. This system furnishes the air supply for the two Babcock & Wilcox boilers of 520 h. p. The system consists of a steam driven fan automatically controlled by the Beckman system of valves. The air is delivered through deflecting dampers in the bridge walls under the grates, into the closed ash pits. The principal feature of the system is the automatic regulation which controls the speed of the fan by the steam pressure in the boiler. The engine running faster when the pressure falls below a fixed point, increases the supply of air under the grates and causes the fires to respond quickly to the increased demand made upon them. When the pressure rises above the desired point, the engine slows down gradually, and reduces the supply of air and the amount of steam generated. The following advantages are claimed for the Beckman system: Burning cheaper grades of fuel; increased capacity; increased efficiency; reduction of repairs; complete regulation.

J. JONES & SON, of New York, are located at the right hand side of the Garden by the first stairway leading to the Promenade about the main floor. Against this stairway is placed a very handsome switchboard containing different switches of the Jones make, and constitutes a sample of a thoroughly up-to-date board, such as they are putting out continually. On one side is shown the Jones electric cut-off and the Jones automatic time switch and also electric time cut-off switches of their cheaper make. The right hand side is occupied by a row of their panel boards of different styles.

At the rear of the space and against the wall there is an exhibition board showing the different makes of the Jones bracket fixtures, small switches, etc., and a counter upon which are shown different electric portables manufactured by Jones & Company.

In the foreground facing the aisle is a table upon which is shown a quantity of heating apparatus, and to the right hand side there is a third table with the Jones medical battery apparatus, alarm clocks and goods of kindred description.

Over the center there is hung a new arc lamp which will be put upon the market at an early date.

THE AMERICAN WATCHMAN'S TIME DETECTOR COMPANY, of New York, exhibit their well known American watchman's time detector, which is used by the night watchmen in the Exhibition building, registering upon the machine in the company's exhibit, with stations located throughout the building. There will also be shown the company's electric time system, consisting of master clock and secondaries, a number of which clocks are used throughout the Exhibition, driven by the master clock in the exhibit; and separate from this are shown the company's electric time system for private house use, consisting of a hall clock (grandfather's clock), with chimes, as master clock, driving a series of mantel clocks, and these clocks are noiseless, moving the hands at intervals of ten seconds. This is the same system which the company are putting in at the Waldorf-Astoria, connecting 700 secondary clocks to one master clock, making, when completed, the largest clock plant in the world, as well as the largest clock order ever placed, except one that is slightly larger, also captured by the company. Besides these there is shown their street post clocks in the same circuit with other clocks; school program clocks; three different varieties of time recorder for employees, all mechanical. Also an interior telephone system and fire alarm system for hotels, isolated plants and factories.

THE BOSTON BLOWER COMPANY'S exhibit consists of a 90-inch top horizontal, full housing exhauster, with a direct connected 6 x 6 inch vertical engine. The machine is to be used in connection with the Kensington Engine Works Beckman System of forced draft for furnishing blast under Babcock & Wilcox boilers.

H. B. KIRKLAND is displaying quick break switches and arc cut-outs manufactured by the Hope Electric Appliance Company, of Providence, R. I., the circuit breakers and flush switches manufactured by the Cutter Electrical and Manufacturing Company, of Philadelphia, the rheostats made by Mr. Charles Wirt, of Philadelphia, and the conduits made by the American Circular Loom Company and the Boston Electroduct Company.

KEUFFEL & ESSER COMPANY'S exhibit consists of drawing materials and surveying instruments. Of the former they have, besides drawing instruments proper, drawing papers, blue print papers, etc., a specially interesting collection of measuring instruments which are largely used by the electrical professions, that is, slide rules, calculating instruments, and protractors. At the last Exposition their exhibit commanded considerable interest, and undoubtedly will this time also.

THE AMERICAN ELECTRICAL AND MAINTENANCE CO.'S exhibit consists of methods of repairs for emergency calls, and brushes and extensions manufactured by them; also the patent adjustable turning tool, for turning down commutators without removing them from the fields. This turning tool is now on sale, heretofore only having been on loan or hire by the patentee. They have now made arrangements to manufacture and sell the same.

THE K & W COMPANY make an excellent exhibit consisting of their standard incandescent lamps, together with street series and miniature and decorative lamps. They also show their absolute cut-out hanger boards, spark arrester, K & W dynamo brushes, fan motors and commutator compound. They also have an illuminated sign made of miniature lamps in series, giving name of company and name of lamp. Mr. C. Houliston, of their New York office, is on hand to show their goods and welcome their customers.

THE BOSSERT ELECTRIC CONSTRUCTION CO. are showing a complete line of steel drawn outlet and switch boxes, representing the latest improvement in wall boxes as they are constructed entirely of one piece of wrought steel, being absolutely indestructible and thoroughly fireproof. They also exhibit carious types of steel clad self-contained main junction and distribution boxes. This type of box is designed especially to meet the objection of the underwriters and electrical engineers generally to a combustible wooden box enclosing a panel board. They are thoroughly fireproof and are designed for any number or arrangement of circuits, with or without switches.

THE ZIMDARS & HUNT exhibit consists of their electric light and power specialties, such as knife switches; panel, feeder and connection boards; automatic switches and motor starters; connections; bar work; lugs, etc. All types of the Zimdars & Hunt "all copper" knife switch in single, double and quick break are shown, together with the drawn copper back connections lately introduced by them. Three types of their improved voltmeter and galvanometer switches are also exhibited and prove interesting to numerous visitors on account of the many novel features they embody.

The panel and feeder board exhibit is a marvel in showing the very latest and most approved practice in this line. All the standard types and many of the special ones are shown mounted on a variety of marbleized slates and marbles. The effort has been to make this the most complete exhibit of feeder and panel boards ever attempted. All types of the well known Zimdars & Hunt automatic switches and motor starters are on exhibition and a new and desirable type of the automatic motor starter is here shown for the first time, and receives considerable attention. Among the many articles of merit exhibited should be mentioned a new and serviceable removable wall plug and receptacle, here shown for the first time. This device, it is believed, answers the long felt and often expressed want for a plug that sets flush with the wall when inserted in its place, thereby allowing the door to be kept closed at all times. Besides the above, a variety of other devices, too numerous to mention, are shown.

A novel feature of the exhibit is a complete bar copper railing at the front of the booth representing switchboard bar work.

THE NOWOTNY ELECTRIC CO. make a representative display of their well known products.

THE VACUUM OIL CO., Rochester, N. Y., are making an exhibit of lubricating oils such as are supplied by them for electrical machinery in all parts of the world.

THE PARTRIDGE CARBON CO. have their self lubricating motor and generator brushes on exhibition and Mr. James Partridge is looking out for their interests.

THE FISCHER FOUNDRY AND MACHINE COMPANY have a tandem compound, double valve, centre crank, self-oiling, automatic engine, direct connected to an Onondaga dynamo. This engine is of about 10 h. p.

THE NILES TOOL WORKS CO. exhibit at the Electrical Exhibition two pyramids of the all wrought steel pulley, one of which consists entirely of pulleys with faces over 8", all provided with the new rim clamp, which they have just applied to their pulleys.

THE ONONDAGA DYNAMO CO. have on exhibition a 75 kilowatt generator direct connected to a tandem compound Fischer engine. The generator is fitted with reacted carbon brushes. The electrical and mechanical construction of the generator is said to be of the latest improved pattern of dynamo construction.

THE R. THOMAS & SONS CO.'S exhibit consists of a liberal display of high voltage glaze filled insulators. They also will have their testing apparatus in place in the booth showing the manner in which the insulators are tested, and a small press and die showing the process of making porcelains by die work.

PERU ELECTRIC MFG. CO. are found exhibiting a full line of Peru specialties, such as "Peru" style branches and mains, Sawyer-Man branches and mains, Edison style blocks, "Peru" multiple tablet boards, transformer fuse blocks, all sizes and styles of insulators, cleats and tubes and also Laclede and Hercules batteries.

THE O. S. PLATT MFG. CO.'S exhibit consists of double pole snap switches from 5 to 100 ampere capacity. Flush switches, flush lock switches, double and single pole push button switches, 3 pole and 500 volt switches, knife switches for motors and lighting, from the "Baby" size to 1,000 amperes. The exhibit will be in charge of Messrs. Wood and Shaw.

THE BULLOCK ELECTRIC MFG. CO. make an exhibit of four different types of their apparatus, comprising the following: One 25 kilowatt engine type multipolar generator; one 25 kilowatt belted multipolar generator; one 10 h. p. enclosed ceiling motor, and one 7½ h. p. moderate speed belted motor. There is other apparatus of this company installed in connection with certain exhibits.

THE EDDY ELECTRIC MFG. CO. are represented by H. B. Coho & Co., and their exhibit consists of their new six pole machines arranged for direct connection, their new double voltage plater, new line shaft motor, and some of their standard apparatus. They expect to operate a 75 kilowatt Warren Alternator, working 1,100 and 100 volts off the same machine, and driven by an Eddy motor.

THE JOHN STEPHENSON COMPANY are making an interesting exhibit in which is shown a model car one-quarter actual size; being a full working model of the standard car used by the Metropolitan Street Railway Company of New York, on their underground electric system. Besides this there is a standard car in operation; also showing the standard car used by the Metropolitan Street Railway Company of New York on their underground electric system.

THE JOHN THOMSON PRESS CO. are exhibiting their half medium Style 2 press. Its trade name is "Colt's Armory" press, and built for them by the Colt's Arms Co., of Hartford, Conn., being designed by Mr. John Thomson. This press is used by practically all of the leading concerns in the United States and Great Britain, in the production of the finest grades of half tone and color printing. At the Exposition the press is shown direct connected to a Bullock motor.

THE BABCOCK & WILCOX CO. have furnished two boilers of 265 h. p. of their complete forged steel construction built for 200 pounds working pressure. These boilers are to supply steam for the Exhibition. They are part of a plant of 16,000 h. p. sold to the Metropolitan Street Railway Company for the new 96th street power house, and are furnished by the Babcock & Wilcox Company for use during the Exhibition by special permission of the Metropolitan Street Railway Company.

THE NEW YORK SAFETY STEAM POWER CO.'S exhibit comprises a vertical automatic cut-off engine direct connected to a Fort Wayne generator. This is one of their latest designs of vertical engines especially built for electrical work and heavy duty.

PORTER & REMSEN'S exhibit comprises a 125 h. p. Fischer, four-valve, tandem compound, automatic, self-oiling, high speed engine, direct connected to a 75 kilowatt Onondaga dynamo. The size of the engine is 9½x15x12 inches, running at a speed of 275 r. p. m.

THE EXCELSIOR ELECTRIC CO. have a very complete exhibit, including arc generators, arc motors, their latest type arc lamp, rotary transformers, single, two and three phase. Single phase synchronous motors, an Otis elevator driven by alternating current, and a line of direct connected and belt driven generators. Their exhibit is in charge of Mr. G. Warner and Mr. H. Hochhausen.

HENRY R. WORTHINGTON has 1,000 square feet in the centre of the Electrical Exposition, where are exhibited a number of different designs of small electric pumps suitable for office buildings and apartments, together with latest designs of automatic rheostats, controllers, and other electrical apparatus which pertain to electrical pumping. They also show about ten different types of larger electrical pumps, combined with electric motors and suitable for hydraulic elevator service, mine service, water work supply, irrigation, fire protection, boiler feed, etc. Among these is an automatically controlled worm geared elevator pump, driven by a 50 h. p. General Electric motor, and also one of their standard horizontal triplex electric mine pumps, driven by a 75 h. p. motor and capable of operating against 1,000 lbs. to the square inch. Their exhibit also includes a collection of framed drawings, showing different installations that have been made by this company which illustrate the most modern improvements in electro-hydraulic pump service.

THE POPE MANUFACTURING CO. have on exhibition representative vehicles of their product, including one of their single seated, Mark III, and one of their double-seated, Mark IV, Columbia motor carriages. It is also their intention to have apparatus in their space illustrative of the simple method of charging electric vehicles. In order to make it possible to afford to those interested an opportunity to test in actual service one of their carriages, it is their plan to have stationed at a point conveniently situated in regard to the Garden, a vehicle which can be employed for riding in adjacent streets.

THE NEW YORK CAR WHEEL WORKS are making an exhibit of "machined" chilled wheels mounted on special cold rolled steel axles of the type in use under all the electric tramways of this country. They have furnished some 10,000 of these axles for the electric tramways in the East in the past ten years, with a case of breakage in service yet to be reported. Another special feature is their interurban wheel, designed for use under electric tramways that run beyond the city limits and attain high speeds after leaving them. The wheel is of the single plate or disc pattern and the object of it is to take up more uniformly the heat generated by the application of the brakes at such high speed.

THE FORT WAYNE ELECTRIC CORPORATION have on the lower floor one 75 kilowatt direct current dynamo direct connected to a New York safety engine. This is one of their latest and most improved type. On the main floor they will have on exhibition operated by motor one 37½ kilowatt alternator, eight or ten motors of various sizes, a quantity of transformers, a quantity of arc lamps of all styles and finishes—long-burning, ordinary arc, enclosed arcs; all styles of globes; a direct coupled 100 light arc machine to a 15 h. p. motor with their latest and most improved automatic regulator, latest design of switchboards, instruments, meters, etc.

WILLIAM S. HAINES COMPANY'S display consists of "Heintz" steam traps, of the standard sizes, floating thermometers for manufacturing purposes, thermo regulators, pressure regulators, and a new practical thermometer, the figures on which being placed on a dial 3½ ft. in diameter, are capable of being read at a distance of 100 ft. with ease. This thermometer is on the "Heintz" principle, and is said to be absolutely correct. They also exhibit the "Heintz" Naval Alarm, which is adjusted to indicate the exact temperature in one part of the vessel at another part situated possibly several hundred feet distant. It is adjusted so as to ring a bell when the temperature in any of the apartments controlled reaches a certain point.

L. KATZENSTEIN & CO. make an exhibit consisting of their metallic packing for piston rods and valve stem stuffing box for steam engines, pumps, ammonia compressors, etc. Flexible tubular metallic packing for slip joints on steam pipes, improved slip joints, and metallic gaskets for all kinds of flanges. Mr. Katzenstein is one of the oldest manufacturers of metallic packing of all kinds.

MACHADO & ROLLER are exhibiting a full set of portable and switchboard, direct and alternating current Whitney and Hoyt instruments; a full line A. E. G. incandescent lamps; one or two exhibition switchboards made by W. S. Hill Electric Co.; small collection of special and standard Perfection dynamo brushes made by Ohio Electrical Specialty & Manufacturing Company; some sample elements of storage battery made by the Ohio Storage Battery Co., and some sample carbons for enclosed arc lamps made by F. Hardmuth & Co.

THE NONPAREIL CORK MANUFACTURING CO. is on hand with a full line of their insulations for rails, wires, etc.; sectional insulating coverings for steam, refrigerator and water pipes; block and plastic insulating coverings for boilers, heaters, tanks, kettles, flues, etc.; sheet cork insulation for heat, cold, sound and vibration in cold storage and all refrigerated rooms, floors and walls; boiler room ceilings, high speed engine and heavy machinery beds, etc.; floor and wainscot tiling, friction clutch blocks. Their Nonpareil cork steam pipe and boiler covering is used throughout the Electrical Exhibition.

THE PECKHAM TRUCK COMPANY exhibit one of the 14-B short wheel base swivel trucks and one of their 14-D swing bolster maximum traction trucks. This company is also exhibiting one of its Metropolitan special high speed single trucks under the car body shown in the Stephenson Car Co.'s exhibit. Particular attention is drawn in this truck to the long spring base which is a sure preventative of oscillation and to the rigid center brace, which removes the strain of keeping the truck square with the car body. There will also be found in the Walker Co.'s exhibit one of this company's 7-B-X Excelsior trucks, showing a different arrangement of the cantilever side frame design, which is the distinguishing feature of the Peckham single trucks.

H. B. COHO & CO. represents, among other concerns at the Exposition, the Eddy Electric Mfg. Co. and the Warren Electric Mfg. Co. They will have in operation a 75 kilowatt improved Warren alternator, working 1,100 and 100 volts off the same machine, run by an Eddy direct current motor. They also represent the American Rheostat Company, Milwaukee, Wis.; Crown Woven Wire Brush Co., Salem, Mass.; Diamond Electric Company, Peoria, Ill.; Van Horne, Burger & Co., Dayton, O.; Translucent Fabric Company, Quincy, Mass.; Otis Electric Company, 38 Park row, N. J.; Marietta Mfg. Co., Marietta, Pa.; Pennsylvania Electric Company, Philadelphia, Pa. In addition to the above companies, they will exhibit a full line of switchboards, panel boards, etc.

WOOD, SHAW & CO. are representing a number of well known concerns at the Exposition, and their exhibit will include the carbon and plumbago dynamo and motor brushes of the Partridge Carbon Co.; generators and motors with rheostats and starting boxes of the Quaker City Electric Co.; switches of the snap, indicator, flush, lock and push variety, and all copper slow and quick break switches manufactured by the O. S. Platt Co., of Bridgeport; the non-arcing lightning arrester for light and power, direct and alternating circuits made by the Universal Electric Co., and A. D. French & Co. exhibits under their supervision a line of octagonal wooden poles, plain and treated for electric light and power use. Besides this the Shaw woven wire dynamo brushes are being shown.

THE WARREN ELECTRIC MFG. CO. are represented by H. B. Coho & Co., who will exhibit an improved Warren alternator of 75 kilowatt capacity, and intend to operate same with an Eddy direct current motor. This alternator is connected for double voltage, half the capacity of the machine to deliver current without the use of transformers direct to 110 volt lamps. The other half, connected up for a potential of 1,100 volts on current to be reduced by transformers. The machine is excited by a late improved Warren direct current dynamo, which is a bi-polar machine, over magnet type, and is of an entirely new design, combining many elements of extreme simplicity with exceptionally high efficiency. The alternator is operated at a speed of 800 revolutions per minute, contains no brushes, collector rings or revolving armature; the current being taken from a stationary element of the machine.

BENJ. F. KELLEY & SON exhibit connected up and running one Kelley patent improved Berryman feed water heater and purifier.

THE ARMORITE INTERIOR CONDUIT CO., Pittsburg, Pa., show a full line of their well known Armorite interior conduit, illustrating the various uses to which it is put and setting forth its many advantages.

THE BOSSERT ELECTRIC CONSTRUCTION CO., Utica, N. Y., display steel split boxes for conduit. These boxes are said to be non-breakable and light, and claimed to be the best split conduit boxes on the market.

THE BULLOCK ELECTRIC MFG. CO. are exhibiting one 25 kilowatt engine type generator, one 25 kilowatt belted generator, one 10 h. p. type "N" enclosed motor, one 7½ h. p. type "H" standard motor, and one type "T" controller. The controller is from a recent design and the 10 h. p. type "N" motor is an absolutely new design, this motor being the first turned out of this pattern. It is entirely enclosed, being dust and waterproof, and is designed for use in foundries, on cranes, pumps, etc.

THE ADAMS-BAGNALL ELECTRIC COMPANY, of Cleveland, Ohio, are exhibiting several lamps of each type that they manufacture, both in plain and ornamental finish, namely: Series differential open arc lamps for all night use for 1,200 and 2,000 c. p., series enclosed arc lamps for 2,000 and 1,200 c. p., constant current series enclosed, two in series on 200 volts, constant current series enclosed, five in series on 550 volts and constant potential enclosed for 110 volts and C. O. enclosed lamps, one across 220 volts.

THE NILES TOOL WORKS CO. exhibit one 32"x32"x12' Niles planer with two heads on the cross rail; one Niles turret borer and five-inch lathes. The planer is provided with the company's regular tangent drive running in oil and enabling the planer to be set parallel to the line shaft. The turret borer is of a style rapidly becoming popular, and is designed to turn out very economically, work previously done on the face plates of large lathes. Each of the four largest lathes has the reversing lever placed in the apron instead of the head stock, as is ordinarily done. This enables the workman to control the movement of the carriage without leaving the cutting tool.

THE EDISON MFG. CO. exhibit the following apparatus, which they manufacture: Edison fan motor for the 110 volt direct current, Edison battery motor outfits, Edison-Lalande batteries, Edison electro-medical apparatus, Edison dental motor apparatus for battery, Edison dental motor apparatus for the 110 volt direct current, Edison faradic batteries, Edison cautery transformer for the 110 volt direct current, Edison cautery transformers for the alternating current.

THE NATIONAL PHONOGRAPH CO. occupy one-half the space that has been allotted Mr. Edison, the other half being used by the Edison Manufacturing Company. They exhibit the new Edison standard phonograph, Edison "Home" phonograph, Edison spring motor phonograph, Edison battery phonograph and also a number of special nickel plated and gold plated phonographs.

MR. T. A. EDISON, JR.'S, exhibit is a strikingly attractive one. It consists of a bank of lamps about 8 x 10 feet, arranged in circles. Each circle contains a distinct type of lamp and there will be about fourteen of these circles containing an aggregate of about 900 lamps. There will be 4, 8, 10, 16, 32, and 50 c. p. lamps, plain, frosted, red, blue, amber, green, and opal, spherical, tubular and the regular pear shape lamps. The connections are so arranged that the various parts of the bank can be lighted separately, and one part of the bank is so arranged that Mr. Edison's name appears in red spherical lamps. Connected with the exhibit is a full set of instruments for measuring the efficiency of the lamps and photometric tests will be made if arrangements can be made for the necessary dark room. It is also proposed to exhibit the Edison Junior new 500 volt incandescent lamp. This will be, probably, the only 500 volt incandescent lamp ever made with one continuous filament.

BOGUS TELEPHONE REFORMERS. A couple of well-dressed men have been arrested in New York City on a charge of grand larceny. They went around alleging that they were the accredited agents of a movement to reduce telephone rates, and are said to have gathered in about $500. They used a letter purporting to come from the New York Board of Trade and Transportation.

INVENTORS' RECORD

Classified Digest of U. S. Electrical Patents Issued April 19, 1898.

RAILWAY SIGNALING APPARATUS. H. Bezer, New Rochelle, N. Y., 602,423. Filed Aug. 22, 1893. Comprises a semaphore blade, having a landscape background adapted to make a series of continuous revolutions in a substantially vertical plane, and to assume a defined predetermined position, to indicate the condition of the track.

SIGNALING DEVICE FOR RAILWAY CARS. F. W. Diehl, Detroit, Mich., 602,434. Filed Sept. 28, 1897. A device designed to take the place of a push button.

RAILWAY SIGNAL SYSTEM AND APPARATUS. H. Bezer, New Rochelle, N. Y., 602,792. Filed Dec. 3, 1895. Semaphore signal provided with a main and a reserve battery.

Batteries, Secondary:—

INVERTIBLE FLUID BATTERY. P. R. Cunningham and C. H. Howland-Sherman, Washington, D. C., 602,616. Filed Feb. 20, 1897. Details of construction.

Conductors, Conduits and Insulators:—

INSULATED PIPE COUPLING. G. Peeples, Philadelphia, Pa., 602,564. Filed June 19, 1896. A joint comprising an upper section connected to but insulated from the gas-pipe and having notches in its lower end, a lower section having on its upper face a series of grooves registering with the notches, and means for connecting the two sections together.

BRACKET FOR INSULATORS, ETC. J. R. Fletcher, Dayton, O., 602,576. Filed Jan. 4, 1896. Comprises a head for the insulator and a blade having one flat side and two recessed sides and tapering from butt to point, adapted to be driven into a supporting surface.

Distribution:—

APPARATUS FOR REDUCING ELECTRIC CURRENTS AND VOLTAGE. A. F. Vetter, Long Island City, N. Y., 602,709. Filed Sept. 3, 1895. Combines with the supply circuit, a current reducing resistance placed in the supply circuit, a shunt, including translating devices, and means for transferring one or more of the sectional resistances in the supply circuit to the shunt circuit.

Electro-Metallurgy:—

ALUMINUM REDUCING POT AND MEANS FOR TAPPING SAME. A. Dickey, Niagara Falls, N. Y., 602,575. Filed Nov. 12, 1897. A pot provided with a taper tap-hole and a charcoal plug fitted to the taper, and means for excluding the plug from contact with air.

Measurement:

ELECTRICAL MEASURING INSTRUMENT. H. W. Sullivan, London, England, 602,527. Filed Nov. 6, 1896. Comprises an oscillating coil, a core therefor and magnets in whose field the coil oscillates, having poles with pointed extremities brought into close juxtaposition with portions of the core without interfering with the movement of the coil.

ALTERNATE CURRENT METER. C. P. Feldman, Cologne, Germany, 602,557. Filed Dec. 21, 1897. A zero adjustment for alternate current meters.

Miscellaneous:—

APPARATUS FOR LOCATING OBSTRUCTIONS IN TUBES. B. C. Batcheller, Philadelphia, Pa., 602,422. Filed Sept. 28, 1897. Consists of an apparatus for visually recording time intervals; means for co-ordinately recording sound waves, the means being connected with the tube to be tested, so that sound waves created in the tube will be visually recorded.

VALVE CONTROLLER. A. E. Colgate, New York, 602,429. Filed Sept. 19, 1896. Employs an auxiliary valve. Details of construction.

ELECTRIC CONTROLLER FOR GAS REGULATORS. W. E. H. Williams and P. Seiler, San Francisco, Cal., 602,548. Filed May 13, 1897. Comprises an inlet valve operated by a float inside the regulator, a supplemental weight adapted to be added to the float or removed therefrom by means of electromagnets being charged or discharged by electric currents.

PROCESS OF SMELTING PHOSPHORUS. C. K. Harding, Chicago, Ill., 602,747. Filed April 5, 1897. Maintains an electric arc below the surface of the material in an atmosphere of hydrogen and continuously supplies the reducing agent through the fused mass.

ELECTRICAL MUSCULAR EXERCISE. E. Sandow, London, England, 602,774. Filed Jan. 24, 1898. An apparatus provided with handles attached to elastic cords; wires attached to the handles and so united with the cords as to be capable of extending with them.

ELECTRIC FURNACE. G. G. Clark, Galveston, Tex., 602,815. Filed Feb. 3, 1897. Comprises a revoluble fusing pot having an electrical connection therewith, a carbon electrode supported above the pot, and means for automatically feeding the material inward toward the carbon electrode as the pot revolves.

Railways and Appliances:—

TROLLEY WIRE HANGER. W. A. McCallum, Cincinnati, O., 602,463. Filed Aug. 16, 1897. Consists of a holder, an insulated bolt seated therein and having a toothed upper surface; a screw-threaded cap having a corresponding inner face, the suspending end of the bolt threaded oppositely from the cap, and a compressible washer interposed between the cap and the insulated bolt.

ELECTRIC CONTACT SHOE. W. M. Brown, Johnstown, Pa., 602,495. Filed Nov. 14, 1896. Comprises a flexible contact strip, a supporting frame comprising a bar parallel to the strip, and a cushion extending from end to end between the bar and strip.

ELECTRIC RAILWAY. H. W. Libbey, Boston, Mass., 602,584. Filed Dec. 10, 1894. Closed conduit electric railway system.

TRAVELING CONTACT FOR UNDERGROUND ELECTRIC RAILWAYS. G. B. Coleman and J. W. Duggan, Washington, D. C., 602,678. Filed Nov. 2, 1897. A traveling contact having two pairs of leading wires provided with independent couplings and independently connected to the contact shoes of the device.

STREET INDICATOR. E. J. Hall, St. Louis, Mo., 602,746. Filed Nov. 3, 1897. Details of construction.

APPARATUS FOR CONTROLLING ELECTRIC MOTORS. A. J.

Stopher, London, England, 602,781. Filed Feb. 16, 1898. Designed for electric locomotives.

Switches, Cut-Outs, Etc.:—

ELECTRIC SWITCH. A. G. McPherson, Highland Park, Ill., 602,767. Filed May 1, 1897. Employed for alternately cutting out one generator or source of supply and throwing in another. Details of construction.

CLOCK CONTROLLED SWITCH. F. L. Mackey, New Castle, Pa., 602,706. Filed Nov. 10, 1897. An automatic switch, comprising a desk having locking stops spaced thereon and carrying switch points, means acting on the disc to rotate it, a pawl engaging the stops to hold the disc, fixed switch points attachable to the circuit, and means operated by a clock to momentarily lift the locking pawl.

Telephones:—

ELECTRICAL APPARATUS. H. H. Eldred, Brooklyn, N. Y., 602,-596. Filed April 4, 1896. A telephonic apparatus comprising a magneto instrument for signaling; a receiver; a signaling circuit, including the armature of the signaling instrument; a telephone circuit; a switch to cut out the receiver and transmitter from the signaling circuit, and a second switch to bring the receiver into the signaling circuit.

THE STOCK MARKET

A Firm Market.

Much of the uncertainty of the last few weeks was dissipated by the declaration of war ten days ago. The result has been a marked stiffening in prices and an advance in values all along the line. The advance in cereals has been particularly marked, and, as usually follows in such cases, its effect has been beneficial to all values. So far as the electrical industries are concerned, the large Government orders still keep the factories busy, many working nights to deliver on time. This applies not only to large apparatus, but most of the smaller supplies which go with the former. The victory at Manilla is probably the beginning of the end, and we shall probably see an early reversion to normal peace conditions.

During the week the sales of General Electric were 2,500 shares, closing at 32⅛; Western Union, 4,584 shares, closing at 76⅞; American Bell Telephone closed at 247, the same as the week previous, on sales of 585 shares.

Steel rails are selling at $20; copper, lake ingot, 12.10c.

SOCIETY & CLUB NOTES

American Institute of Electrical Engineers.

The 124th meeting of the Institute was held on Wednesday, April 27. Mr. H. Ward Leonard in the chair. About sixty members and guests were present. A paper on "An Economy Test of Central Stations" was presented by Prof. W. E. Goldsborough, of Lafayette, Ind.; also a paper on "A Novel Form of Thermo Electric Battery," by Mr. C. J. Reed, of Philadelphia, which was accompanied by experiments. The discussion was participated in by Messrs. Cox, E. P. Thompson, Mailloux, Reed, Wintringham, Steinmetz, and Mr. W. M. Mordey, of London.

At a meeting of the Executive Committee in the afternoon the following associate members were elected: Wyatt H. Allen, care H. F. Allen, 202 California street, San Francisco, Cal.; Wm. H. Fitzhugh, superintendent Bay City Electric Plant, Bay City, Mich.; John Breckenridge Fleming, mill superintendent and consulting engineer, Austin Mining Co., Austin, Nev.; Geo. J. Henry, Jr., engineer for N. Y. Branch, The Pelton Water Wheel Co., 143 Liberty street, New York City; N. S. Hopkins, assistant engineer, General Electric Co., Box 825, Schenectady, N. Y.; Robert Lindsay, general superintendent, The Cleveland Electric Illuminating Co., 717 Cuyahoga Building, Cleveland, O.; Frederick A. Muschenheim, electrical engineer, Western Electric Co., 57 Bethune street, residence, 41 W. 31st street, New York City; Newton L. Schloss, consulting engineer, 39 Cortlandt street, residence, Stuart House, New York City; Clarence M. Tolman, electrical engineer, with Edw. G. Stoiber, Silverton, Colo.; Ernest Stiles Vinten, draughtsman, Walker Co., New Haven, Conn., residence, 89 Pearl street, New Haven, Conn.

The Northwestern Electrical Association.

The arrangements for the excursion meeting of the Northwestern Electrical Association are going on apace. Secretary T. R. Mercein and Mr. J. M. Hill, chairman of the Special Entertainment Committee, are now in the East in the interests of the association, and report most gratifying success.

The association has issued a number of special invitations to prominent electricians to be the guests of the association, among them Messrs. Edison, Tesla, Thomson, Brush, Stanley and Wood, and some of these have promised to attend if their engagements permit.

It is the intention not to make the excursion to Duluth a junket; on the contrary, business will be adhered to strictly. The value of the meeting will lie not only in the papers to be submitted, but in the topical discussions which have been arranged for, and in the answers to the question box. A number of experts in the various departments of the large electrical companies will be present and participate in the discussions.

PERSONAL

W. F. Osborne.

MR. W. F. OSBORNE, who for the past eight years has been the able Eastern representative of the Western Electrician, will on May 1 sever his connection with that paper and will thereafter be identified with the "National Provisioner" as business manager. This journal, which is the leading paper in its field, is published weekly. The proprietor of it is Dr. J. H. Senner, formerly Commissioner of Immigration, and also formerly editor of the "Staats Zeitung" and is a gentleman well known in the newspaper field. Mr. Osborn, who has won for himself a host of friends in the electrical fraternity, enters upon his new duties with the best wishes of all those, whose admiration he has won by his frank and courteous manner at all times. It gives us pleasure to acknowledge our indebtedness to Mr. Osborne for the numerous favors received at his hands and to wish him all possible success in his new undertaking.

Hill & Howard.

Mr. Nicholas S. Hill, Jr., having severed his connection with the city of Baltimore, as Chief Engineer of the Water Department on Monday, March 14, has associated with himself Mr. B. C. Howard, intending to engage in a general consulting business under the firm name of Hill & Howard. Mr. Howard is a graduate of the electrical department of Johns Hopkins University, and was formerly secretary and treasurer of the McCay-Howard Engineering Co., general contractors for electrical work. Mr. Hill is a graduate of the Stevens Institute of Technology in Hoboken, and has subsequently occupied the positions of mechanical engineer of the South Side Elevated Railroad in Chicago, a description of which appears in this issue; Engineer and Secretary of the Sewerage Commission of Baltimore, engineer to the Electrical Subway Commission of Baltimore, and Chief Engineer of the Water Department. They are now in the field for general engineering, including plans, specifications, reports, estimates, tests, etc., etc. They make a specialty of water works systems, electrical subways, electric light and power plants and transmission of power.

MR. THOMAS R. MERCEIN, the well known secretary of the Northwestern Electrical Association, is spending a few days in New York, looking after the interests of the association, arranging details for the coming convention and seeing his many friends in this city.

Messrs. Ford, Bacon and Davis, engineers, have removed to the Singer Building, 149 Broadway, New York.

REPORTS OF COMPANIES

General Electric Co.'s Sixth Annual Report.

We print below full abstracts from the annual report of the General Electric Co. to be submitted at the stockholders' meeting on May 10.

President Coffin's report reads as follows:

The past year witnessed a revival in business which increased rapidly in activity and volume during its latter months. A careful scrutiny of the assets of your company, other than its patents, leads to the belief that previous values were conservatively fixed, and no changes of any significance have been necessary. The patent account of the company has been kept at substantially the same amount on its books since the organization of the company. The question of a revaluation of patents is one to which consideration should be given at the proper time.

BUSINESS OF THE YEAR.

Gross earnings	$12,524,938.07	
Less expenses	10,727,692.02	
		$1,797,246.05
Interest and discount, and interest and dividends received on securities owned	389,789.16	
Less:		
Interest on debenture[1]	333,333.35	
		56,455.81
		1,853,701.86
Deduct amounts written off:		
Sundry losses and allowances for possible losses	79,220.42	
Patents and patent expenses	333,334.68	
Inventories and consignments	89,665.70	
Reserve for extensions to factory plants	250,000.00	
	752,220.80	
Less:		
Profit on securities sold and debentures canceled	130,371.31	
		621,849.49
Reduction of the deficit of previous years		$1,231,852.37

In addition to the purchase of $2,000,000 of debentures referred to in previous annual reports, your company has purchased during the year just ended $2,000,000, and the entire $4,000,000 have have been destroyed. Since the books were closed $290,000 additional have been acquired, and are now held in the treasury of the company. An increase is shown in the amount received from interest and dividends from securities owned. In anticipation of the investment in the construction and equipment of new shops, which it is estimated will cost about $500,000, the sum of $250,000 has been deducted from the profits of the past year and carried to factory reserve account.

Consolidated Balance Sheet of January 31, 1898.

Assets.			Liabilities.		
Patents and Franchises		$ 8,000,000 00	Capital Stock:		
Factory Plants		[illegible]	Common	$ 30,460,000.00	
Real Estate (other than factory plants)		[illegible]	Preferred	4,252,000.00	$ 34,712,000.00
Stocks and Bonds		[illegible]	5% Gold Coupon Debentures		6,000,000.00
Cash		[illegible]	Accrued Interest on Debentures	50,000.00	
Notes and Accounts Receivable	$ [illegible]		Accounts Payable	[illegible]	[illegible]
Work in Progress	[illegible]				
	[illegible]				
Inventories:					
Factories	$ [illegible]				
General and Local Offices	[illegible]				
Consignments	[illegible]	[illegible]			
Profit and Loss		[illegible]	Reserve for Extensions to Factory Plants		250,000.00
		$ 41,[illegible]			$ 41,776,[illegible]

At the annual meeting of the stockholders, held four years ago, the question of reducing the company's share capital in the manner prescribed by law, was referred to the directors. Since that time the matter has had the earnest attention of your board, and it is their hope that a plan will be submitted for your consideration at an early date, designed to provide for a suitable reduction of the share capital of the company, with a view to the resumption of dividends.

THE PATENT SITUATION.—The patent situation has not materially changed since the last report to the stockholders. The company has secured many important patents during the year, by inventions of its engineers and experts and by purchase.

One of the Van Depoele trolley patents which had been uniformly sustained by the courts up to last summer has been adversely passed upon by the Court of Appeals for the Second Circuit. This decision was on a motion for preliminary injunction and is not final. In view of the fact that nearly all of the railway companies in the country that would be likely to use the overhead trolley system are now electrically equipped, and that the third rail and underground conduit methods are being rapidly adopted for the important new enterprises, an adverse decision in this case will have but slight effect upon the business of your company.

The report of First Vice-President Griffin reads as follows:

I submit herewith a condensed report of the operations of the sales department for the fiscal year ending Jan. 31, 1898:

Total sales (amount billed to customers)	$12,396,093
Cost of goods sold, general expenses and taxes, including sundry losses and allowances for losses	10,896,578
Profit on sales	$1,499,515

From this profit should be deducted debenture interest, etc., as shown in the report of the second vice-president.

Our sales for 1897 are somewhat less than our sales for the previous year, while our orders are considerably in excess of the orders secured in 1896. The following figures are based on orders secured and not on sales.

Consolidated Profit and Loss Account of January 31, 1898.

Expenses.			Earnings.		
Balance January 31, 1897		$ 12,[illegible]			
Cost of Goods Sold	$ [illegible]		Sales	$ 12,396,093.49	
General Expenses, Taxes, Sundry Losses and Allowances for Losses	[illegible]	10,896,578.14	Royalties and Sundry Profits	[illegible]	$ 12,[illegible]
			Dividends and Interest received on Stocks and Bonds owned	[illegible]	
Interest on Debentures		333,333.35	Interest and Discount	[illegible]	389,789.16
			Profits on Sale of Stocks and Bonds	[illegible]	
			Discount on Debentures Purchased and Canceled	[illegible]

E. & O. E.

I. P. ORD, *Second Vice-P.*

LIGHTING DEPARTMENT.—We have received during the past year orders for 60,826 kilowatt capacity of arc and incandescent lighting machines as against orders for the year 1896 of 57,476 kilowatt capacity, an increase of 5.8 per cent.

RAILWAY DEPARTMENT.—Orders received (money value) for railway apparatus has shown an increase of 33⅓ per cent. over 1896. Orders for railway generators aggregated over 60,000 kilowatts. The average size of the railway motor has increased to 34.7 h. p., while the average railway generator for 1897 was 484.3 h. p., as against 356.3 h. p. in 1896.

POWER AND MINING DEPARTMENT.—Orders for direct current and induction motors aggregated 19,531 h. p. as against 15,171 h. p. in 1896. Orders for multiphase generators aggregated 49,902 h. p. as against 25,007 h. p. in 1896. Total transmission lines installed in connection with G. E. apparatus, 326 miles as against 232 miles in 1896. The orders for 1897 were 60 per cent. over those for 1896.

SUPPLY DEPARTMENT.—The supply department has handled 114,229 separate orders during the year, or 43 for each working hour. The "orders received" in 1897 exceeded by 20 per cent. the "orders received" in 1896. The supply stocks carried at our local offices have been decreased about 7 per cent. during the year, and of the present total, 90 per cent. consists of active supplies, a great improvement over previous years.

The following are some of the principal articles handled by the supply department:

Wattmeters.—Total number ordered during the year 36,874, an increase of 42 per cent. over 1896.

Measuring Instruments.—Total number ordered during the year 3,369, an increase of 38 per cent. over 1896.

[1] On $8,000,000 for four months and on $6,000,000 for eight months.

Transformers.—Total number ordered during the year 11,499, an increase of 36 per cent. over 1896.

Arc Lamps.—Total number ordered during the year 24,158, an increase of 75 per cent. over 1896.

Sockets and Receptacles.—Total number ordered during the year 2,357,629, an increase of 36 per cent. over 1896.

FOREIGN DEPARTMENT.—The orders of the foreign department have shown a gratifying increase over the orders for 1896. Several notable contracts have been placed with us by our foreign companies—the equipment of the Central London Underground Railway, and the equipment of the street railways in several European cities.

INCANDESCENT LAMP SALES.—The incandescent lamp orders for the year aggregated 6,857,239 of which 6,706,624 were shipped. This is an increase of about 10 per cent. over the year 1896.

The report of Third Vice-President Rice is devoted to the manufacturing department and to the increase in manufacturing facilities. Mention is made of the erection of a new foundry having 94,000 square feet of floor space: also an addition of 36,000 square feet to the testing and assembling departments.

Vice-President Rice also enumerates a number of large plants installed or contracted for. There are at present G. E. transmission plants aggregating 100,000 h p., among them twenty installations operating at over 10,000 volts transmitting a total of over 50,000 h. p. to distances varying from ten to forty miles.

Following is Second Vice-President Ord's report:

ASSETS.

PATENTS AND FRANCHISES.—During the year there was expended for acquiring new patents and in patent litigation, $333,334.68, all of which has been written off to profit and loss; leaving the patents, franchises, good will, etc., of the company standing unchanged at $8,000,000.

FACTORY PLANTS.—The changes in this account since the last annual report is as follows:

	Jan. 31, 1897.	Jan. 31, 1898.
Book value of Schenectady plant....	$2,157,000.90	$2,300,000.90
Book value of Lynn plant..........	993,000.80	900,000.80
Book value of Harrison plant........	250,000.30	200,000.30
Totals	$3,400,002.00	$3,400,002.00

STOCKS AND BONDS.—No changes of last year's figures have been made in the book valuations of stocks and bonds. Those having a market value are carried under the price of reported sales. The book value of those not readily salable was fixed on January 31, 1897, after careful examination of their worth. I believe the actual present aggregate value of all these securities is equal to the total amount at which they stand on the books, viz., $7,455,872.96. Stocks and bonds of subsidiary companies were sold to the value of $1,038,054.80.

CASH.—The policy of the previous three years has been adhered to and sales maintained on a basis of cash or short credit to desirable customers. None of the money realized from the sale of assets was required for the current business of the company during the year.

NOTES AND ACCOUNTS RECEIVABLE.—This account represents the total amounts now due the company by its customers.

They appear in the balance sheet at an estimated realizable value (i. e., their face, less a total allowance of $662,614.66 for possible losses) which I believe to be a fair one.

INVENTORIES.—The inventories of the factories showed an excess over book value of $275,097.72, which is not taken as a part of the year's profit, but is retained as a reserve. All other inventories showed a shrinkage from book value of $79,238.39, which has been written off as a loss for the year. Goods are taken in and out of local office inventories at factory cost at the time being. The bulk of the above shrinkage is due to factory costs at January 31, 1898, being lower than at January 31, 1897, and to writing down the book value of slow selling apparatus and other personal property.

The net book value of consignments is $52,734.79.

LIABILITIES.

The company has no notes payable, nor is any paper bearing the company's indorsement of guaranty under discount. All purchases have been paid for in cash. It has not been necessary to borrow money, nor has the company's credit been used during the year either by issuing notes, indorsing customers' paper for discount or lending its name in any way.

DEBENTURES.—During the year the company has purchased and canceled $2,000,000 of its own 5 per cent. gold coupon debentures due June 1, 1922, at an average of 99.30 per cent.

ACCRUED INTEREST ON DEBENTURES.—This account, as its name implies, is the full amount of 5 per cent. interest accrued to January 31, 1898, on the company's $6,000,000 outstanding debentures.

ACCOUNTS PAYABLE.—This account includes all unpaid audited indebtedness. At the close of business on January 31, 1898, there were no unpaid vouchers on hand.

RESERVE FOR EXTENSIONS TO FACTORY PLANTS.—This account represents $250,000 set aside, from the profits of the business of the past year, toward the cost of erecting and equipping at the Schenectady plant an iron foundry and a machine shop which are estimated to cost about $500,000.

The correctness of the financial statements is attested by Messrs. Patterson & Corwin, certified public accountants.

TRADE NOTES & NOVELTIES

Kinloch Telephone Co., St. Louis.

The Kinloch Telephone Co., St. Louis, are making rapid headway with the equipment of their great plant. As a result, they expect to be in a position in a comparatively short time to afford St. Louisans an independent telephone service. The latest of the large contracts which the company have entered into in this connection is for their annual wants in galvanic batteries and their respective parts. This contract, which was awarded to the Phoenix Carbon Manufacturing Co., of St. Louis, is said to be the largest of its kind ever placed, and was sharply competed for by carbon manufacturers from all over the country. It was given the local company, for their well-known Phoenix No. 1 carbon cup cell, after a test by experts.

Central Electric Company's New Quarters.

A visit to this company's new quarters, No. 264-266-268 Fifth avenue, Chicago, will well repay those in the electrical trade. The first thing which impresses one on entering the building is its enormous size, the floor space being 80 ft. front by 140 ft. deep, extending to a large and commodious alley, which facilitates the handling of goods from wagons and drays. The front part of the store is divided into five handsome office suites, finished in quartered oak. Back of these offices, arranged in convenient manner are shelves, containing a large stock of general supplies, such as lamps, shades, Okonite wire, porcelain goods, railway supplies, electrical glassware, etc. On one side of the building are specially built fireproof vaults for stationery and advertising matter.

The large basement has a number of freight elevators for the quick handling of goods, cement floored, light and airy, and is of the same size as the store above. It is to be used for the storage of heavy wire, pins, brackets, cross-arms, etc. In short, the whole establishment has been arranged for the carrying of a very large stock of electrical supplies, for their convenience of handling and for beauty as well. The Central Electric Co. ranks among the largest supply houses in the world, and The Engineer wishes them continued prosperity in their new quarters.

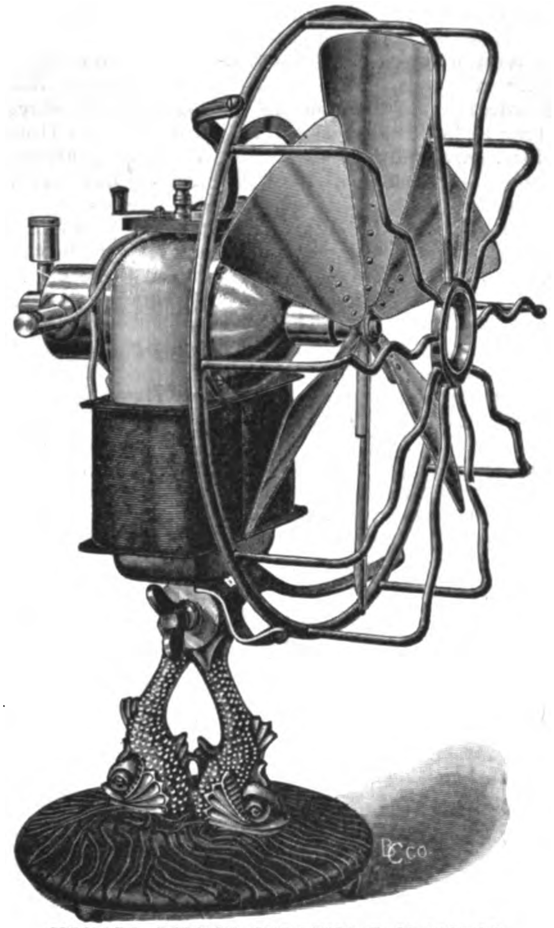
A New Haven Electrical Bridge.

The Berlin Iron Bridge Company, of East Berlin, Conn., have just completed at Grand avenue, New Haven, Conn., a steel bridge 427 feet in length, 52 feet in width, with one roadway and two sidewalks. The approaches on the bridge consist of two deck plate-girders. The draw span is 200 feet in length and is operated by electricity; the same means being employed for lighting the bridge throughout. The bridge is of very heavy construction, the roadway being paved with vitrified brick adapted to the heavy city traffic.

Noxall Fan and Power Motors.

THE Noxall 1898 motors, manufactured by the Vance Electric Company, 136 Liberty St., New York, have recently been placed on the market. The fan motor, illustrated below, is exceedingly graceful in outline, and nothing has been lost sight of in obtaining a perfect operating and highly efficient machine. The pole pieces are of mild steel, carefully milled and accurately fitted to steel templets, all exposed parts highly polished and nickel plated on copper. The armature is of the ironclad slotted, Pacinotti type, carefully mounted on solid steel shafts with laminated annealed rusted iron discs. All conductors are carefully laid in and secured by the usual binding wires. This construction admits of the armature running with minimum air gap. All armature wires are accurately fitted to commutator bars and brazed. The commutator is made up of hard tempered copper, drop forged bars and thoroughly insulated by best India mica.

The bearing cases or bonnets of brass are firmly secured to the pole pieces on each side and wholly enclose the armature

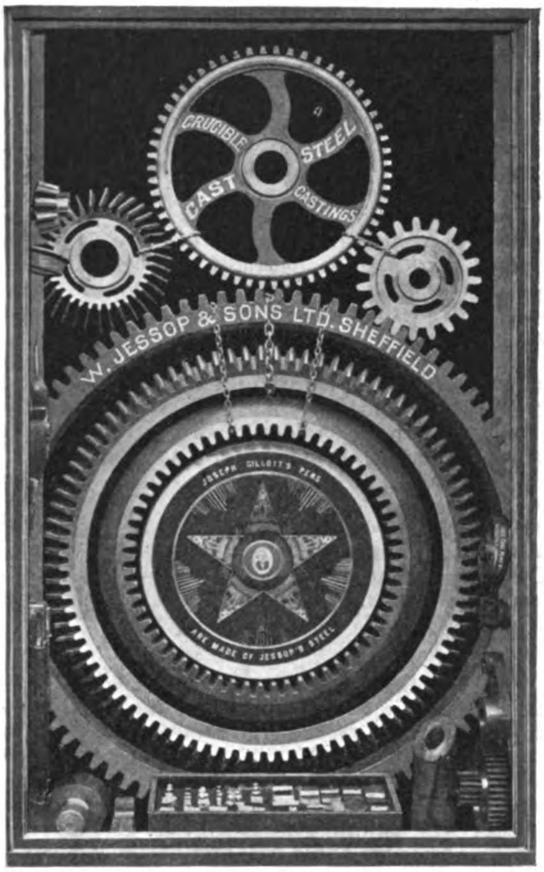


NOXALL DIRECT CURRENT FAN MOTOR.

and commutator, insuring absolute protection to the vital parts of the machine. The journals are long and are self-lubricating by small grease cups. An occasional turn of the cup, say, once a week, when first putting the fan up to run is all that is required. There is sufficient grease in the cup to last one season. The bonnet at commutator end carries the brush holders which are neat cylinders holding carbon pencils kept in contact by spring pressure. The carbon used is a special kind insuring even contact is self-lubricating and prevents sparking. The brush cylinders afford easy means of inspection and adjustment as they are screwed through the bonnet on opposite sides. The switch for giving three speeds and the terminals for receiving current connections are mounted on hard rubber on the top of the machine across pole pieces and have proven to be more handy and less liable to give trouble than when in the base. This switch gives the fan three speeds: 1,800, 1,400 and 900 revolutions per minute. Lower speeds can be furnished when desired on special order. These motors are built for direct or alternating current circuits and for any desired voltage.

A Display of Jessop's Steel.

A VERY interesting exhibit has recently been shown in the windows of William Jessop & Son, John street, New York, consisting of a tasteful arrangement of crucible steel castings, cast car and gear wheels, cutter blanks, tool steel and other products of the Jessop works. This exhibit is illustrated in the cut shown below and contains within the central gear wheel a handsome show case containing a collection of steel pens of the celebrated Gillott brand made of Jessop steel and arranged in



DISPLAY OF JESSOP STEEL PRODUCTS.

star form showing the various styles of this celebrated pen for which steel is used. The whole arrangement is well worth the inspection of those interested in metals, and is one of the brightest displays in John street.

Elkhart Transformers at Weston, O.

Oswald Bros., of Weston, O., under date of April 16 have sent the following to the Kuhlman Electric Company, makers of the new Elkhart transformers, at Elkhart, Ind.:

"We have had the 75 one light transformers purchased of you last month, installed and in circuit all night for the past fifteen days and have been watching results very carefully and must say, that so far as we can see, up to the present time they are a success. We get better efficiency than we expected and a 16 c. p. lamp operated in this way is giving better satisfaction in this town than 32 c. p. lamps are giving in surrounding towns. If we have any more installations for incandescent street lighting, we shall use nothing but the small transformers."

Roe & DeBonneville.

The above is the name of a firm recently formed by Mr. Charles J. Roe and Mr. A. A. DeBonneville, M. E. Mr. Roe has had twenty-five years' practice before the courts and Mr. DeBonneville is a mechanical engineer of twenty years' experience as well as an attorney-at-law. The combined experiences of these gentlemen eminently fit them for the preliminary examination, preparation and prosecution of applications for patents, trade-marks, etc., and also to prosecute all litigation in reference to patents, etc.

The offices of the firm are at Room 621, Bowling Green

Building, New York, and at No. 1 Montgomery St., Jersey City, N. J.

A Lighting Plant for Alaska.

The Electrical Exchange, Chicago, has just shipped a complete lighting plant to the Alaska Transportation & Mining Association, St. Michaels, Alaska. This outfit will be used to light one of the companies' steamboats plying on the Yukon. One of the Midget Upton enclosed arc lamps (for which the Exchange has recently taken the agency) will be used to light the prow of the steamer. The Exchange reports a gratifying increase of business during the month of April.

Special Applications of Westinghouse Apparatus.

Problems of special difficulty have been solved by the Westinghouse Electric and Manufacturing Company in the construction of the apparatus recently shipped for the works of the Carborundum Company, of Niagara Falls. 1,000 h. p. is supplied at voltages varying from 80 to 200. The work involves special difficulties on account of the wide range of voltage and the very large currents carried. The apparatus as designed by the Westinghouse staff is of high efficiency and power factor, unusual virtues in most of the so-called electrical machinery built for this class of service.

The Westinghouse Electric and Manufacturing Company is to supply the electrical apparatus for the new plant of the Detroit, Ypsilanti and Ann Arbor Railroad Company, consisting of four 300 h. p. generators, three boosters, switchboards, and ten car equipments, including forty 50 h. p. motors.

Niagara power is still being developed by Westinghouse apparatus. The Westinghouse Electric and Manufacturing Company has recently sold to the Niagara Falls Power Company two 500 h. p. rotary transformers, three 500 kilowatt lowering static transformers, and the complete switchboard, for operating the street railway system of North Tonawanda, N. Y., between Buffalo and Niagara Falls.

The Wood, Shaw & Co. Business Consolidation.

We take pleasure in calling attention to the fact that the business of Mr. Joseph S. Wood, electrical engineer, of 25 Park Row, and that of Mr. H. M. Shaw, manufacturers' agent, 126 Liberty street, New York city, have been merged into the firm of Wood, Shaw & Co., manufacturers, exporters and dealers in electrical specialties, with general offices at 40 Broad street, New York. The shops of the new firm are fully equipped with machinery, tools, help, etc., for turning out the highest grade of work in the quickest time possible. This consolidation places the combined business on a basis of unlimited resources and facilities for engineering, manufacturing and selling the specialties heretofore handled individually. Prompt attention and satisfaction is guaranteed on all orders intrusted to the firm.

Mica and Micanite Agency, Cleveland, O.

Eugene Munsell & Co., and the Mica Insulator Co., of New York and Chicago, last week completed arrangements with the George Worthington Co., of Cleveland, whereby they become distributors of both "Mica" and "Micanite." Their territory includes the city of Cleveland and some eight or ten of the adjoining counties.

A large stock of India and Amber "Mica," in the sheet and segments for railway motors, as well as "Micanite" plate, segments, rings, cloth, paper, etc., will be carried to supply the electrical trade in that section.

This is an important step in the right direction, and the trade in Cleveland and vicinity will appreciate the fact that this stock has been placed in the hands of so large a company, who have the facilities for making prompt delivery.

MR. GEORGE W. PATTERSON reports that on or about May 1 the two companies he represents—the American Circular Loom, Flexible Conduit and the Gordon, Law and Phœnix Batteries—will remove from 1114 to 1539 Marquette Building, Chicago, and invites all old friends and customers to come up and have a bird's-eye view of the city.

The Conduit business was never so good before, and is increasing, while the merits, and especially low prices of the Phoenix batteries, are beginning to be recognized in a very flattering manner.

Large Sales of the C & C Electric Co.

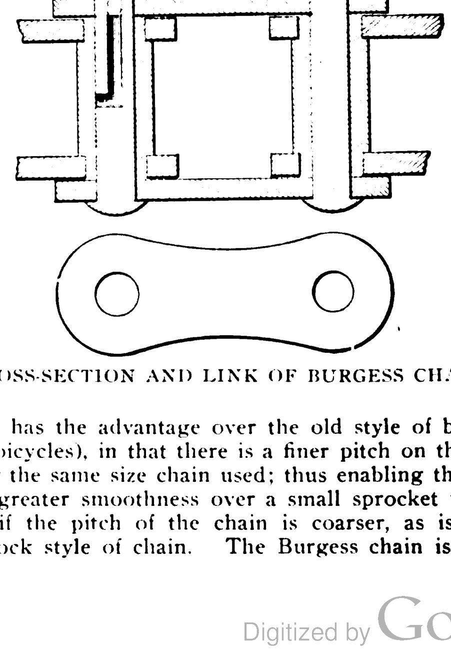
It seems that the war has not, at least up to the present time, had a very injurious effect upon the business of the principal electric manufacturing companies, and we are advised that the C. & C. Electric Company in particular are very busy. While a number of their orders during April came from the Government, orders were also very numerous from other quarters. In New York city and vicinity, while they sold as usual a very large number of small dynamos and motors, they secured an order for two 30 kilowatt direct connected generators and a 9 h. p. motor and a three panel switchboard to be installed at the Grand Union Hotel; an order for three 30 kilowatt direct connected generators to be installed in the Ward Building, No. 707 Broadway; an order from A. Trenkmann, tortoise shell manufacturer, for a 30 kilowatt belt type generator, and an order from one of our largest wholesale houses for a 100 kilowatt direct connected generator.

Their Pittsburg office, besides making a number of sales of small machines, sent in an order for a 20 kilowatt generator direct connected to the Weston engine with switchboard, to be installed for the Cambria Brewing Company, of Johnstown, Pa.; an order for three 30 kilowatt generators to be direct connected to three Weston engines and installed at the Custom House and Post office at Pittsburg. Their Mr. J. C. Lucas at Baltimore secured orders for three 30 kilowatt generators of the direct connected type to be installed at the Louisville Custom House and Post Office, besides orders for several belt type generators and motors to be installed in Washington and Baltimore; their Philadelphia office sent in their usual large number of orders for machines for Philadelphia and Eastern Pennsylvania, as well as an order from the Government for a complete lighting and power plant for Fort Delaware, consisting of a 100 h. p. boiler, two 40 h. p. Ames engines, two 30 kilowatt direct connected generators, switchboards and booster plant and everything necessary to make a complete power and lighting installation. Their Boston office as usual contributed its quota.

Their London representative, Mr. C. R. Heap, sent in orders for some ten or twelve Ironclad motors; their Chicago representatives, Messrs. Sargent & Lundy, never fail to send in frequent orders and April was no exception, as their orders covered several good sized generator and motor equipments. The company's other agents also sent in their share of orders, all of which have gone to make the month of April a very busy one for the C. & C. Electric Company.

Special Steel Chains Manufactured by the Boston Gear Works.

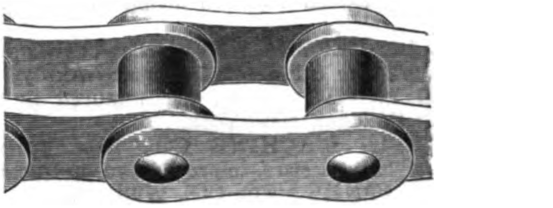
The Boston Gear Works, 31 Hartford street, Boston, Mass., Frank Burgess, proprietor, manufacturers of gear wheels, are placing upon the market a superior steel chain for which many decided advantages are claimed. One of the principal improvements which have been made in this chain, which is shown in the accompanying cuts, is the case hardening of the sleeve, which adds a great deal to the durability of the chain. The



CROSS-SECTION AND LINK OF BURGESS CHAIN.

chain also has the advantage over the old style of block chain (used on bicycles), in that there is a finer pitch on the sprocket wheels for the same size chain used; thus enabling this chain to run with greater smoothness over a small sprocket wheel than it would if the pitch of the chain is coarser, as is necessary for the block style of chain. The Burgess chain is admirably

suited for electric carriages, where it insures a saving of power and a smoothness of running. The company make a specialty



BURGESS CHAIN, FULL SIZE.

of intermittent gears, on which subject they publish a very interesting pamphlet. Details of these gears and other products of the company will be published later.

George C. Towle Manufacturing Co Chartered.

A charter has been issued to the George C. Towle Manufacturing Company to manufacture electrical machinery at Lancaster, Pa. The directors are G. C. Towle, J. E. Hubley and R. Blickenderfer, Lancaster, Pa.; G. A. Towle, Lowell, Mass., and J. P. Williams, of New York. The new company has the contract for making the Paragon fan and power motors for the season of 1898.

Large Order for the Ball Engine Co.

The New Vancouver Coal Co., Nanaimo, British Columbia, has ordered a 175 h. p. engine from the Ball Engine Co., Erie, Pa., for electric mining purposes. The Chappell Chemical Co., of Hegewisch, Ill., will have an electric light plant. A "Ball" engine furnishes the power. The American Ordnance Company, Lynn, Mass., has ordered through J. H. Houghton, Boston agent of the Ball Engine Company, Erie, Pa., a 125 h. p. engine for use in Government work. These orders speak well for the Ball Engine Co., Erie Pa., who build engines exclusively for electric purposes. The enviable reputation of the "Ball engine" has no doubt much to do with the satisfactory condition of their order book.

Northern Elec. Mfg. Co.'s New Agency.

Kohler Brothers, 1645-48 Monadnock Block, Chicago, have just taken the sales agency for the Northern Electrical Mfg. Co., of Madison, Wis., for the States of Illinois, Iowa, Missouri, Indiana, Nebraska, Kansas, Kentucky, Tennessee, Michigan, Ohio, Pennsylvania, New Jersey, Maryland, Delaware, and District of Columbia; and are now prepared to figure on all kinds of direct current electrical apparatus up to 250 kilowatts.

CATALOGUES.

The Consolidated Telephone Construction and Mfg. Co., Ltd.

A very instructive and attractive catalogue of receivers, transmitters, magneto bells and generators has just been issued by the Consolidated Telephone Construction and Manufacturing Co., Ltd., located at 186-188 Shaftesbury avenue, London, W. C. The catalogue contains numerous illustrations of all kinds of telephone and telegraph apparatus besides a number of useful electrical diagrams. The catalogue measures 9½ x 12½ inches, has a handsomely engrossed cover and in every way does justice to the excellent products turned out by the company.

General Electrical Co.'s New Fan Catalogue.

A very handsome fan motor catalogue has just been issued by the General Electric Co. illustrating their 1898 alternating and direct current fan motors. Their alternating current motors, which have been illustrated in our pages, are made for 52 and 104 volts, 60 and 125 cycles. The electrical construction of these motors has been carefully designed and thoroughly tested. The various parts are as carefully proportioned and as in larger machines, no fear of excessive wear or heating need occur when fans are operated continuously. The motors are finished in black enamel and nickel plate. The same applies to the direct current motors which are fully described and illustrated in this highly artistic and useful catalogue.

The Globe Carbon Company.

The various uses to which carbon is put for electrical work are ably set forth in a pamphlet recently issued by the Globe Carbon Co., of Ravenna, Ohio. An innumerable variety of arc light carbons are illustrated, plain as well as copper-coated. These moulded carbons have a correct mechanical finish, are electrically low in resistance, which insure a bright clear light of great steadiness, and the copper-coated carbons have just the proper copper coating to avoid the forming of copper globules. The company also manufacture Le Clanche and dry battery plates of great variety, carbon brushes and back plates and diaphragms for telephone work. They make a specialty of carbon cylinders, filament blocks, carbon flour, and are the manufacturers of the standard Fuller cell, the Hayden cell and supply the trade with chemicals and other appliances for primary batteries.

Harrison Safety Boiler Works, Philadelphia, Pa.

A very handsome and artistic catalogue describing the Cochrane heaters and elucidating the full value which can be obtained from exhaust steam for heating and purifying feed water and for heating systems, published by the Harrison Safety Boiler Works, of Germantown Junction, Philadelphia, Pa., has just reached our office. The catalogue contains, besides numerous beautiful half tone cuts, articles on "Why Feed Water Heaters Are Used," and comparisons of open and closed heaters, the Cochrane heaters, a story of steam heating and all about the Cochrane separators.

Barnes Metal Working Machinery.

A very neat catalogue has just been issued by the W. F. and John Barnes Company, of Rockford, Ill. Disk drill presses and upright drills of all kinds, screw presses, emery grinders, lathes and hand-turning tools, chucks, and every variety of machine tools are illustrated in his admirable circular and price list.

Dearborn Drug and Chemical Works, Chicago, Ill.

Two very handsome and neat booklets setting forth the advantages of boiler compounds manufactured by the Dearborn Chemical Works, have been received at this office. The handsomely engrossed cover of one of them bears the significant motto, "An ounce of prevention is better than a pound of cure," also advising users of boilers to be sure that they are right. The cover of the other booklet bears the inscription, "Inspection Brings Knowledge," and the book contains valuable data on chemical tests of water. These two booklets will be sent to any one on application.

Electric Light Supply Catalogue of the Western Electric Co.

The new Electric Light Supply catalogue which has just been issued by the Western Electric Co., New York and Chicago, is perhaps the most complete catalogue of its kind ever issued by an electrical supply house. It is a handsome cloth bound book, containing 555 pages, and covers by text and numerous illustrations only such material as is specially adapted to electric light work. To get some idea of the enormous issue of this catalogue which the company has compiled, it may be stated that the edition weighs 20,000 pounds, and if the catalogues were piled on top of each other they would make a column 1,000 feet high, and if placed upon the ground, end to end, they would form a line over 6,666 feet long. The book is carefully indexed, so that the articles can be found under several headings. Valuable tables and a list of electrical books are appended. The book should be in the hands of all users of electrical apparatus, and will be furnished to the trade upon application.

NEW YORK NOTES.

THE ELECTRIC ARC LIGHT COMPANY announce the removal on May 1 of their New York office to 120 Liberty street, the home of the Pioneer enclosed arc.

MR. WM. S. TURNER, M. S., the well known consulting and constructing electrical and mechanical engineer, has removed his offices from No. 1 Nassau street to the new Washington Building, 141 Broadway, N. Y. Mr. Turner has had a large and varied experience, which is shown by a long list of companies whom he has served as engineer.

WARD LEONARD ELECTRIC CO., BRONXVILLE, N. Y., enumerate sixteen reasons why their circuit breaker is the best on the market. Among these may be mentioned the absence of auxiliary knife switches, in series with the circuit breaker, and of auxiliary levers; the certainty of its opening on overload current; the impossibility to close circuit breaker when overload condition exists on the circuit; the impossibility of the switches sticking or failing to open; advantages of the iron clad solenoid magnet; the perfect switch contact, and mechanical construction; the ability to trip the circuit breaker by hand; the small space it occupies; the impossibility of an operator being hurt when the circuit breaker opens; the excellent finish throughout, and last but not least, this circuit breaker can be manufactured much cheaper than any other.

WESTERN NOTES

MR. JOSEPH M. HILL, Western manager of Bryan Marsh Company, manufacturers of the Imperial incandescent lamps, 1239-1240 Monadnock Building, Chicago, was a welcome visitor in New York last week.

THE CENTRAL ELECTRIC COMPANY claim that their stock of house goods is the most complete stock of the kind. The increased orders for goods in this department give evidence of the popularity of large stocks and favorable prices.

MR. H. J. GILLE, formerly Western representative for the Washburn & Moen Mfg. Co., with headquarters in St. Paul, has been appointed general superintendent of the St. Paul Gas Light Co. and the Edison Electric Light & Power Co., of St. Paul. These companies control all save one of the electric lighting plants, and the gas plant. They have the city lighting contract. Mr. Gille is well and favorably known throughout the entire Northwest, being for many years connected with the General Electric Co., both in St. Paul and Chicago. His numerous friends will be glad to learn of his good fortune.

ADVERTISERS' HINTS

CROCKER-WHEELER ELECTRIC CO. advertise power generators.

GEARS OF EVERY STYLE and size are manufactured by the Boston Gear Works, 27 Hartford street, Boston, Mass.

THE FARIES MFG. CO., Decatur, Ill., say to look for their exhibit at the Electrical Show at the Garden.

"PHOTOGRAPHIC ADVICE" is the title of a complete photographic manual with illustrations, descriptions of apparatus and prices. It is sent for ten cents by the Scoville & Adams Co., 60 East Eleventh street, New York.

THE MONTAUK MULTIPHASE CABLE CO. publish a list of the patents under which their cables are manufactured.

THE FUEL ECONOMIZER CO. will have their apparatus on exhibition at the Madison Square Garden.

THE GERLACH HOTEL will be found convenient in every way to the Exhibition. Mr. Baker, of the Exposition Co., is making it his headquarters.

THE VANCE ELECTRIC CO., 136 Liberty street, New York, advertise the Noxall direct current fans in three speeds. Their low price and high efficiency make them ready sellers.

DEARBORN DRUG & CHEMICAL CO., Chicago, suggest the lines on which they prescribe a boiler compound to suit the individual case.

THE ONONDAGA DYNAMO CO., 39 Cortlandt street, New York, may be found in the basement of the Garden during the show. They extend a cordial invitation to their friends to call.

THE DE LA VERGNE REFRIGERATING MACHINE CO., New York, are exhibiting a Hornsby-Akroyd oil engine.

EDWARD P. THOMPSON has removed to the Fulton Market Bank Building, New York.

THE GARVIN MACHINE CO., New York, advertise lathes of all styles and sizes, improved and up-to-date.

THE H. W. JONHS MFG. CO., William street, New York, keep commutator rings in stock for all the standard railway motors.

WILLIAMS-ABBOTT ELECTRIC CO., 154-156 Champlain street, Cleveland, Ohio, claim to be the manufacturers of the best magnetos made. They will make special prices on large lots of receivers and binding posts.

THE GENERAL ELECTRIC CO. give some of the details of the St. Anthony Falls power transmission plant described elsewhere in this issue.

CONTENTS.

Department News Items will be found in advertising pages.

ELECTRIC TRANSPORTATION

The New Work of the Metropolitan Street Railway Company of New York.

BY E. W. STEVENSON.

THE Lenox Avenue electric road, which was equipped with the underground trolley a few years ago, has given such excellent service under the severest conditions of weather and traffic, that the Metropolitan Street Railway Company decided some time ago, after a careful investigation of all existing commercial systems of electric traction, to equip a number of its lines in the city of New York with the underground trolley. A number of these roads, the first one of which was the Fourth avenue road, have been in successful operation for a number of months and have given entire satisfaction. The mechanical features of the construction have already been very fully described in The Electrical Engineer and other journals. The latter caused considerable trouble and delay at certain points, such as Fifth street and the Bowery, where the Third avenue cable had to be crossed, and it required a great amount of ingenuity and skill on the part of the engineers to overcome these obstacles without delaying traffic. It is the purpose of this article to present some features of the electrical construction and station equipment, all of which does credit to the Metropolitan Street Railway Company and the numerous firms supplying the apparatus.

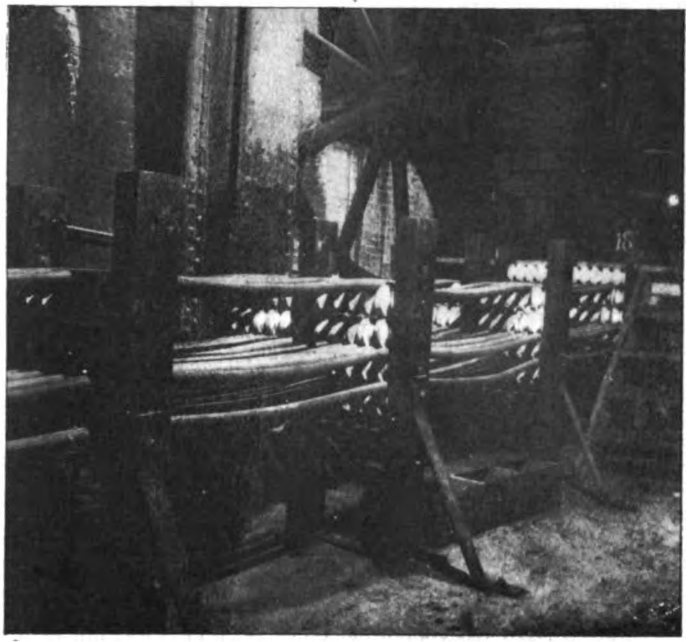

FIG. 1.—LEXINGTON AVE. CABLE TUNNEL HOLDING 14 CABLES

The actual work of laying the cables from the power houses at 25th street and 146th street was commenced in the early part of November last year, when the main feeders were drawn in by two companies—the National Conduit and Cable Co., and the John A. Roeblings Sons' Co. The first supplying a paper cable soaked in rosin oil, and the latter a combination insulation of paper on the inside and saturated jute on top, both makes, of course, being lead covered. The mains in all cases consisted of 1,000,000 c. m. cables, and for the Fourth avenue railway alone from the Brooklyn Bridge to 59th street fourteen of these cables were found necessary. These cables leave the 25th street cable house and are carried through the Lexington avenue cable tunnel, Fig. 1, to a large vault underneath the corner of 23d street and Lexington avenue, where they turn and go to 23d street and Fourth avenue. Here the cables divide, eight going up town and six down town, to various feeding points along the line where the 1,000,000 c. m. cables are tapped into two 500,000 c. m. cables. These two 500,000 c. m. cables run along the whole

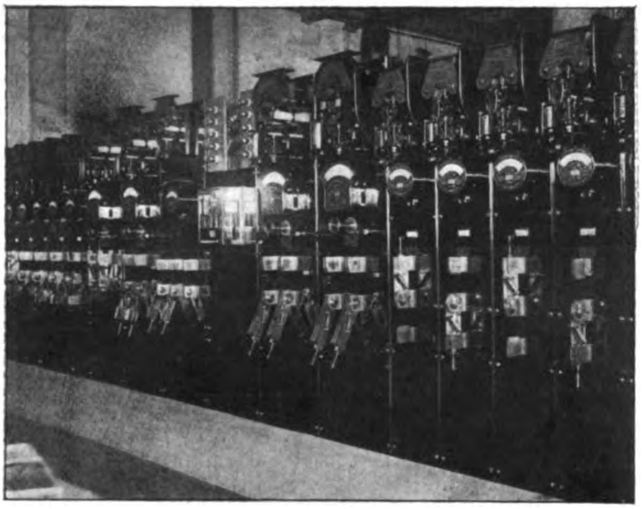

FIG. 4.—FRONT VIEW OF SWITCHBOARD, 25TH STREET POWER HOUSE.

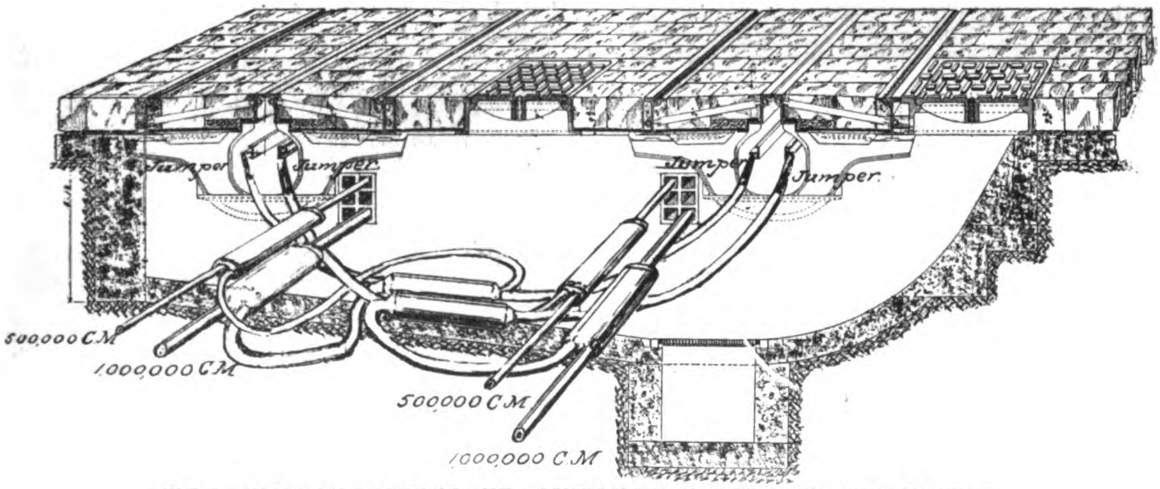

FIG. 3.—DIAGRAM SHOWING THE POSITION OF CABLES, TAPS AND JUMPERS.

length of the road and are cut into sections of various lengths. They are tapped at different points and joined to the feed rails, as shown in Fig. 2. The circuit is entirely metallic, one cable being joined to the east rail and the other to the west rail, and where these taps are made, the east rails on either track are joined by cables called jumpers, as are the west rails, shown in

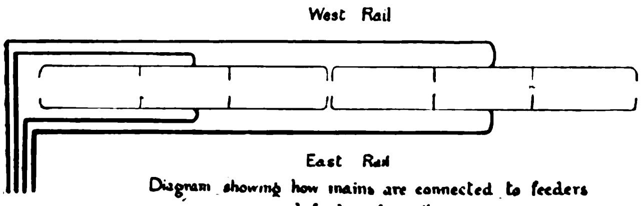

Diagram showing how mains are connected to feeders and feeders to rails

FIG. 2.

Fig. 3. It can be seen that by this system should a cable give out at any time it can be cut dead in an instant and the section joined at either end to the live rail above and below it, because where these different sections end the rails are also cut. Also by this arrangment of feeders the current is evenly distributed along the line and well able to carry any excess due to "bunching up," caused by a block.

The total length of cable used on the Fourth avenue division alone, with Amsterdam avenue branch, amounts to about 150,000 feet of 1,000,000 c. m. and 125,000 feet of 500,000 c. m. of National cable and 100,000 c. m. of Roebling cable, most of the latter feeding from 146th street station.

The stations have nothing particularly novel but are very well

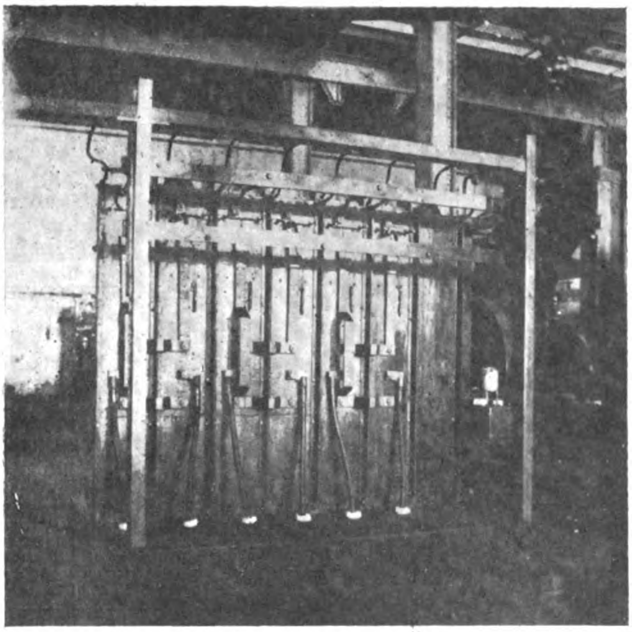

FIG. 5.—BACK VIEW OF SWITCHBOARD, 25TH STREET POWER HOUSE.

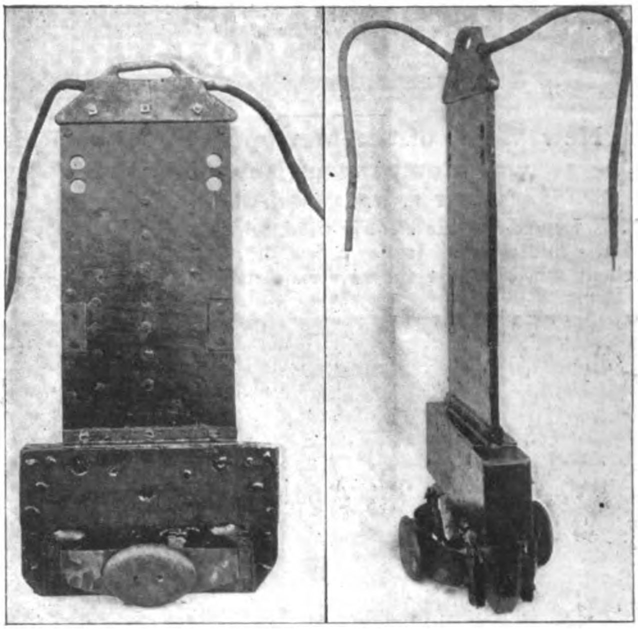
arranged, in fact one would have to travel far to see a finer looking switchboard than that at the 25th street power house; the black, highly enameled slate back sets off to fine advantage the massive switches and neat ampere meters, with an automatic cut-out at the top. Fig. 4 shows the board at the centre with a few panels on either side, and when complete will contain forty panels, each feeder having its own, and operating the Fourth avenue, Second avenue and Amsterdam avenue, and 23d street lines. In the centre of the board will be noticed two series of lamps. When either of these series is lit, it indicates a ground on the east or west rail, according to which series lights up. There is always more or less leakage in damp weather, but even when both sides are comparatively bright, showing practically a dead ground, it does not seem to interfere with the service at all. Occasionally a shoe will short circuit the rails for a few moments, or a bolt carelessly placed by a workman along the line cause a ground, but a quick application of a heavy current usually suffices to burn the trouble off. If not, a corps of trouble hunters is ready at a moment's notice to remedy the defect, so that there is very little possibility of interruption of service. In the centre of the board, underneath the ground detectors, is a recording wattmeter. The back of the board, Fig. 5, shows the large main cables attached to the jaws of the switches,



FIGS. 6 AND 7.—SIDE AND FRONT ELEVATIONS OF PLOUGH.

and also the two heavy copper bus-bars which run the entire length of the board, the lower one being six feet from the ground, while the upper is one foot above that. On either side of the wattmeter are two rheostats which regulate the generators. The engines, four in number, were made by the Pennsylvania Iron Works, and are cross compound non-condensing direct connected, capable of developing 1,500 h. p. each, while the generators are of the General Electric multipolar type, an output of 1,500 amperes at 500 volts, with a speed of 80 revolutions, normal load. The fourth one has just been put in and will be ready to run very shortly. The station has an actual capacity at full load of 8,000 amperes.

Connecting each generator through a large switch is a 2,000,000 c. m. cable to equalize the current, when two or more machines are running. The boilers are of the familiar Babcock & Wilcox type, sixteen in number. They are fed by their well known system of coal supply. There are also several Box self-stoking boilers. This battery also provides the power for the Lexington avenue cable road and the house lighting dynamos. The in-

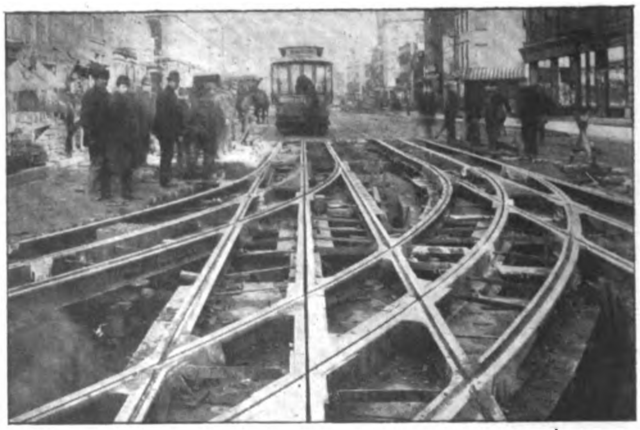


FIG. 8.—TRACK CONSTRUCTION, SHOWING METHOD OF CROSSING TRACKS OF A SIMILAR SYSTEM.

sulator used to support the feed rails is made up of a cast-iron circular cup 5½ inches in diameter, fitted with wings by which it is bolted to the slot rails. Within this cup is another of

porcelain which is held firmly in the former by cement, and which contains a 1½-inch wrought iron shank supporting the conductor rail. The latter is of iron of T-shape and weighs 7 pounds to the foot. It is in 30 feet sections bonded by copper bonds.

The plough, shown in Figs. 6 and 7, has a total width at the slot level of 9-16 of an inch and immediately above and below the slot level is 7-16 of an inch thick. The wear of the slot rails is taken up by tempered steel wearing plates 2½ inches square, and 3-16 of an inch thick. The shank of the plow is made up of three steel plates. The two outside ⅛ of an inch in width, and the middle 3-16 of an inch in width. The conductors which are wrapped with copper ribbons are carried down through the plow to the contact shoes or wipers, connection being made between them by flexible cables. The shoes are about 4 inches by ½ an

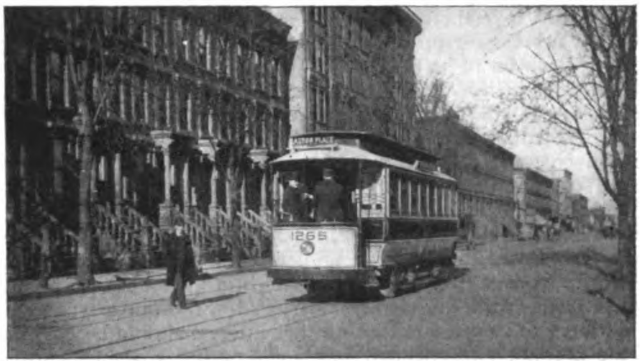

FIG. 9.—A VIEW ALONG FOURTH AVE. AFTER SYSTEM HAD BEEN INSTALLED.

inch and are of cast-iron. The tension is supplied by the side steel springs which keep the shoes extended 8 inches apart when free, and 6 inches apart when in contact with the conductors. The pressure when in contact with the latter is light, being only about 6 pounds.

Fig. 8 shows the details of construction of a crossing, without interrupting the service, and in Fig. 9 is shown how Fourth avenue appeared after the debris had been cleared away and all obstacles had been ably overcome.

Some Early Electric Railroads.

BY J. C. HENRY.

In view of the fact that there has been considerable history manufactured in regard to the first electric railroads, and to combat an official statement made by the Acting Commissioner of Patents in his last annual report that the first commercial electric road was built but ten years ago (presumably the Sprague roads, at Richmond), I send some heretofore unpub-

FIG. 1.—EAST FIFTH STREET ROAD IN KANSAS CITY, 1886.

lished views of historical interest showing my personal efforts in that direction.

The views Figs. 1 and 2 were taken from the East Fifth street road in Kansas City in the fall of 1886. Fig. 3 represents one of the trains on the San Diego and Old Town road in California, taken in the summer of 1887. Fig. 4 represents a view on the Fourth street road in San Diego, which was constructed in 1887. On the latter road, which was about five miles long, we carried as high as 150 passengers up a nine per cent. grade with a single motor. On the Kansas City road we used the double overhead structure. On the Old Town road in

FIG. 2.—EAST FIFTH STREET ROAD IN KANSAS CITY, 1886.

San Diego we used underground feeders with single overhead wires.

All of those roads were supplied from compound wound dynamos. The motor fields were wound with a multiplicity of parallel wires. The motor's resistance was varied with a switch which connected more or less of them together in parallel. The armatures ran constantly and were connected to, or from,

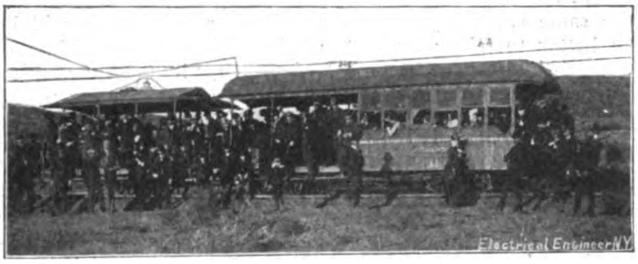

FIG. 3.—THE SAN DIEGO AND OLD TOWN ROAD IN CALIFORNIA, 1887.

the car by a combined differential gear and clutch running in oil. The diminutive trolley engaged the sides and bottom of the trolley wire. The wheels, which ran in a horizontal position, were held to the wire by strong springs. These wheels, which were three inches in diameter, were made of steel tempered "file hard." By using this form of trolley we were en-

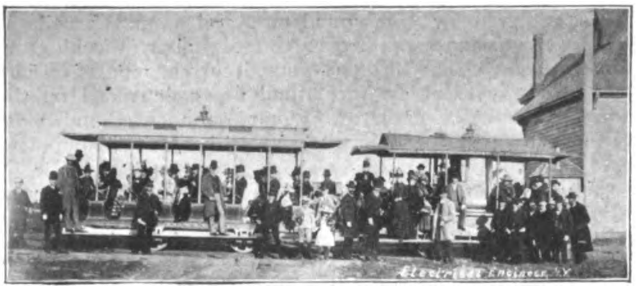

FIG. 4.—FOURTH STREET ROAD, SAN DIEGO, CONSTRUCTED IN 1887.

abled to keep up a traveling contact with the trolley wire which in some cases was 15 feet to the side of the track.

The details of the line construction and motors were worked out and tested by the writer during the years 1884 and 1885 on the Westport Road, and also on the Fort Scott and Gulf road in the suburbs of Kansas City.

MUNICIPAL AFFAIRS

Municipal Electric Lighting—A Reply to Prof. Commons.

BY HORATIO A. FOSTER.

IT has been a pleasure to read Prof. Commons' article on "Municipal Electric Lighting" in the recent issues of The Electrical Engineer, as he, unlike other writers who take the same view, has not applied a very considerable part of his argument to abuse of the motives of the other side. While I most certainly do not agree with the conclusions he teaches, if he may be said to have reached any, I have to thank him for giving a full and candid analysis of all the figures. Time and your space will not permit me to make this reply as full as I could wish, but at some later date, say, after the returns have all been made by the United States Labor Bureau, I may go into the matter more fully.

I would first like to dispel any delusion that Prof. Commons or others may have, that perhaps deep down in my soul I do not really believe in the results of my own investigations as favoring private ownership. While I do not wish to take back a single statement that I may have written and that Prof. Commons has quoted, and will even go farther and say that as an abstract theory municipal ownership seems to have strong arguments in its favor, yet I not only believe it to be wrong in practice but every personal investigation I make still further convinces me that municipal ownership is impractical, more costly any time after the first five years, and in the present condition of our municipal governments, where people are careless of official selection, and the selfishness or self-interest, born of ambition, of the same carelessly selected official is so strong, it will be much better to take advantage of that strong force of human nature, self-interest to the extent of allowing its use for gaining a profit and by proper supervision compel the supply for public uses at reasonable rates and profits. I want to go further and say that outside the very large number of plants that have been installed in villages, where a private plant could not exist and where therefore cost cuts no figure, the establishment of municipally owned plants in many of the larger places has been very largely due to the arbitrary actions and greed of the management of the local plants, and as the most exaggerated instance of this I will cite that latest and most complete plant at Detroit, where the action of local companies is history of recent date.

Now as to accuracy of reports: I think it was mentioned in my report, so largely quoted from by Prof. Commons, that the figures were given for what they were worth only, and when "guesses" were made they were guided largely by experience and not theory. I agree with him that the quality of such work depends largely on the painstaking care of the investigator, but it is impossible to go behind the returns in such cases, especially so where the investigator is representing the "off" side of "Municipal Ownership." Personally I have little faith in statistics gathered by correspondence, and Hon. Carroll D. Wright, Commissioner of Department of Labor, Washington, personally told me that when he wanted correct reports on any subject he always sent an agent, and never depended on the accuracy of statistics gathered by correspondence, and most likely to be made up by some one not having proper equipment or taste for such work.

In spite of our opinions, however, the results of two different investigators occasionally agree in a quite astonishing manner as exhibited by Table III, of Prof. Commons' article.[1]

If I am right in assuming that Prof. Commons agrees that his two investigators are probably correct in all items of operating expenses it leaves only fixed charges for discussion, and there being some question as to the proper place for charging insurance and relinquished taxes, both can be dropped as there seems to be no disagreement about them, and I shall therefore have nothing to say regarding those items. The two main items of dispute then remaining are rates of interest and of depreciation.

It seems impossible to reach any sort of agreement as to interest charges on any plant, public or private, and as regarding the rate "guessed" at by the writer as 6 per cent., I am perfectly frank to say that the rate is high according to our present knowledge, but at the time my report was made up, finances in the West were in such a state as to make borrowing difficult at any lower rate, and it will be noticed that with few exceptions the municipalities for which such "guesses" were made were located in that section of the country.

Prof. Commons disagrees both with the method of Prof. Parsons, in charging interest on the outstanding debt, and with my own of charging interest on the entire cost. I will not take space to analyze the method used by Prof. Parsons but will simply state the reasons for doing as I have in charging interest on the full cost. I have taken as a basis, that municipal financing could hardly be superior to the financing by those in commercial life whose standing and opinions were without question, and, as early in my investigations into cost of steam power this item came up for discussion and was settled for me for all time by those in position to be the best of judges on such points, I have felt perfectly justified in charging interest on full cost as shown. The theory is simply this, that if one invests money in a dwelling house to be used by himself, and pays for it cash down, the real cost to such a person for annual charge on the house, in lieu of rent paid to another owner, will be the interest he relinquishes on the full amount paid for the house.

Now I think there is no municipality so happy as to be entirely free from interest-bearing debt, and if money be taken arbitrarily from taxpayers to build a lighting plant while interest is still being paid on money borrowed for other purposes it would seem to be good reasoning that interest should be charged on the amount appropriated when computing costs of output. The argument that interest charge in a municipality is simply changing money from one pocket to another might apply if each taxpayer held a proportional amount of the bonds on which interest is paid, but such is never the case. It might even have some justification if it were a fact that some bank or individual or association of individuals in the town held the bonds; but when the fact is that it is almost invariably the case that such bonds are bought by outsiders who take the interest away, it would seem far fetched to assume that the taxpayers are saving interest when a new appropriation has to be made for each and every addition to plant.

While it certainly is somewhat difficult to exactly compare the financing of a municipality with that of a private corporation, I repeat that one has to be in the greatest measure guided by those financial methods that have proved the most successful in commercial practice, and I feel perfectly justified in charging full interest on the full cost of plant to the date under consideration.

Taking up depreciation, I am sure that Prof. Commons would confer a distinct favor on the owners of private plants if he could inform them how to make their existing plant last long enough to justify the low charges for depreciation quoted by him as being ample; and if some law of nature could be found that would compel theorists to take a post-graduate course in experience with the subject under discussion, à la Prof. Walter Wyckoff, the results would undoubtedly be to raise the estimates on the costs of carrying out such work.

Prof. Commons very properly divides depreciation into three kinds. viz., "depreciation by use," commonly known as repairs and as such charged into operating expense; "depreciation by competitive improvements"; and "depreciation by replacement."

The first of the three needs no discussion as it is fully agreed that it is a true operating expense.

It is on the second item that Prof. Commons and I do not agree. His discussion of the causes for change of machinery, the saving thereby, etc., is full and complete and I find no cause for disagreement with his conclusions excepting as follows: He assumes that private corporations have been able to stand the strain of constant change of plant, by reason of their ability to charge the same prices as "a decade ago," which he can easily learn is not the case if he will consult some one of the latest lists of municipal prices for lighting. He also says: "Certain it is that the charges by private companies for either public or private lighting have not fallen in proportion to the great improvements in production, etc.," in which he is right; but the very good reason exists for it that under the older condition few of the private companies made a profit of any kind, and the reduced expense accruing from change of plant simply permitted them to in a few cases reach that very desirable condition.

[1]Elec. Engr., p. 265, March 10, 1898.

There seems to have gotten abroad the idea that all electric lighting companies have always made big profits and at every increase of stock or bonds the public in general has cried, "Water!", when in fact it was new life blood infused to permit existence, and if one will only carefully study the annual reports of the Gas and Electric Light Commission of Massachusetts and notice the difference in profits between the gas companies and those electric lighting companies making any profits at all, and then take into consideration that those companies are probably as conservatively managed as any of like business in the country, it pretty soon ought to become evident that the electric business as a business is mighty likely to prove itself short on dividends.

But to return to the subject; he says: "This kind of depreciation is not to be computed as a fixed charge, since it already shows itself in operating expenses by high cost of fuel, labor, repairs, etc." Now this certainly is queer reasoning, for extra money is spent for the new kind of machinery and such expenditure has just as certainly not added anything to the gross earning capacity of the plant, and cannot therefore be added to plant account, and if not, where should the charge be placed? The fact is, that not only has the cost for fuel, labor and repairs been increased by use of the poorer class of plant first installed but the depreciation has been equal to the entire first cost of plant displaced, and the item really merges into the third kind of depreciation or, depreciation by replacements which in ordinary business would mean replacing old machinery by new as fast as the old could not be kept up in efficiency by ordinary repairs. It is the two kinds of depreciation combined that I have always had in mind when charging 7½ per cent. on entire cost of plant.

Prof. Commons tries to prove by example that 7½ per cent. is altogether too high and I have been criticised by others for keeping the rate up, but I am sure that those who are familiar with American practice in the installation of electrical apparatus will bear me out in the rate if they charge off any depreciation at all. Prof. Commons makes the usual error of comparing practice in foreign cities with rates as estimated in the United States. This fallacy should be entirely disposed of by comparing the style of construction in the cities he mentions with that of the usual American city. That at Detroit and some of the later Chicago plants are the only ones that would for a moment bear comparison with those built in foreign cities and I am sure if Prof. Commons had examined personally both financially and technically the something over two hundred and fifty plants that it has been my fortune to do, he would bear me out in the correctness of the rate I have assumed. I have personally visited a number of municipal plants, and while I can freely admit that most of them have been well cared for, the machinery is of the same type and liable to the same troubles as is that owned by private companies.

In addition to the troubles liable in the ordinary running of a plant, that owned by a muncipality has other causes for disaster. Within the past few weeks I have had occasion to discuss such matters with two ex-superintendents of municipal plants; one said that no lighting committee did he ever work under but demanded that for that particular year he would have to run the plant cheaper than for any previous year, and to insure that being the case they would allow no repairs of any nature, the result being that before five years were ended the plant was entirely rebuilt.

The other man was superintendent of one of the Massachusetts municipal plants and was forced out of his position because he would not employ all the help that was tendered him, and which has been employed since the change of management.

Dunkirk is changing that much talked of plant all around, occasion being made for it by reason of the addition of an incandescent dynamo for commercial use. A large new engine capable of driving the whole plant is being erected, the dynamos rearranged, an addition being made to the building, and if good judgment be used throughout, the two or three small and very inefficient engines in use up to now will be abandoned entirely.

Prof. Commons calls attention to the small rates of depreciation reported for Massachusetts. These rates are small as yet but will be gradually increased as the Commissioners become able to induce such increase, as it has been only by the hardest kind of labor that the present rate has been achieved, owing to the very small amount of profit shown.

It is to be hoped that stations erected in the future will embody those features which should bring the rates of depreciation down to those shown by Prof. Commons' article, yet Americans are invariably in a hurry for dividends and demand a quickly built plant, and as such plant can never be low in depreciation I should dislike to prophesy that the necessary improvement would soon be forthcoming.

In conclusion I may say, that until considerably better arguments are brought forward I shall remain of the opinion that interest rates will be nearer 5 per cent. than four in most of the Western States and that 7½ per cent. depreciation is none too great to charge on plants as now constructed for municipal or private ownership.

MISCELLANEOUS

Armature Reactions in a Continuous Current Dynamo.

BY C. A. BESSEY.

IN the Junior laboratory course in Electrical Engineering at the University of Nebraska, the following study of armature reaction, made jointly by myself, Mr. R. S. Mueller, and Mr.

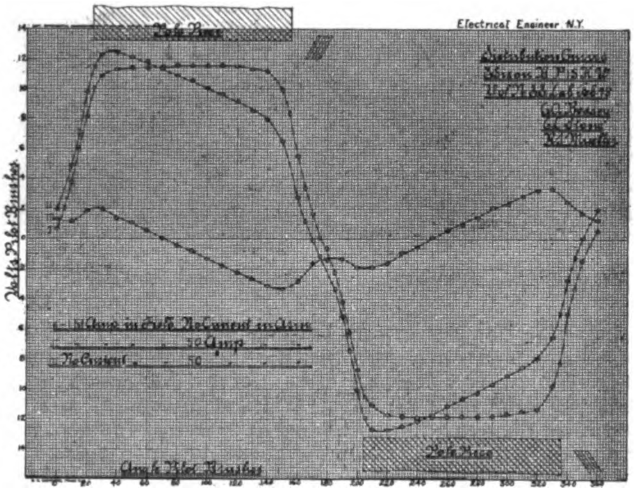

FIG. 1.

C. E. Stone, gave results of such clearness that they may be of interest to others. It being desired to show exactly the extent of the influence of the armature upon the field in both simple shunt and compound machines, it was decided to take three sets

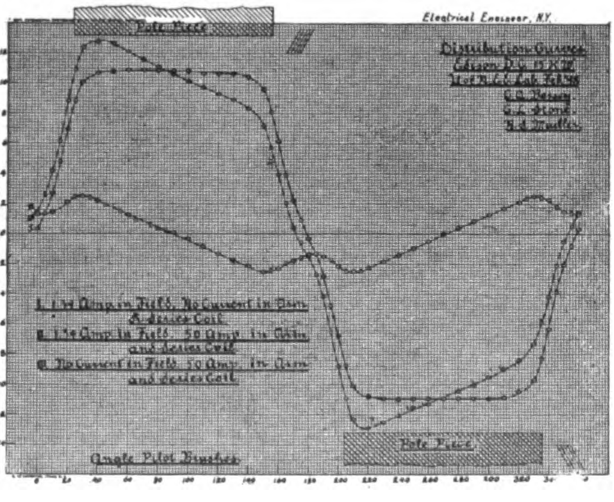

FIG. 2.

of curves in each case as follows: First, the induction distribution with field excited and no current in armature; second, with field excited and 50 amperes in armature; and third, the induction

distribution with 50 amperes sent through armature from an external source and field magnetism previously reduced to zero.

The machine experimented upon was a 15 k. w., 125 volt, Edison bi-polar dynamo run at 1,600 r. p. m. The induction distribution was obtained by measuring with a Weston voltmeter the e. m. f. between two steel watch spring pilot brushes bearing on commutator and shifted into different angular positions. Wirt collector brushes were used and after being given proper lead for non-sparking at 50 amperes, were fixed in this position through the experiments. In the experiments, both as a simple shunt and compound machine, the e. m. f. between collector brushes when loaded, was 110 volts.

Referring to Fig. 1 for simple shunt machine, curve I shows the induction distribution with 1.51 amperes in field and no current in armature. It is seen that the induction distribution is nearly uniform over the pole face. Curve II shows induction distribution with same current in field and 50 amperes in armature. Here the weakening of leading and strengthening of trailing pole tip is apparent. Curve III shows induction distribution with 50 amperes through armature in same direction and field magnetism zero.

It is of interest to note that curve II is almost exactly the algebraic sum of curves I and III, as it of course should be. It is also noticed that curve III does not cross the horizontal axis under collector brushes, as erroneously indicated by Jackson and others. Indeed, were it not for the increased reluctance in the path of the armature lines between opposite pole tips, curve III would be a maximum at the point of commutation. The effect of lead is seen to cause curve III to become zero about 20 degrees from the centre of the pole instead of being zero in the middle of the pole face, as would be the case were lead absent. Compounding coils changes this as will be seen later.

In Fig. 2, curve I shows distribution with current of 1.34 amperes in field and no current in armature, and is of course similar to curve I, Fig. 1, but its ordinates are not so great. In this case, however, because of the series magnetizing turns, the shunt current was reduced to 1.34 amperes to make the main brush voltage 110 as before. Curve II, Fig. 2, is practically the same as curve II, Fig. 1, as it should be under the conditions. Curve III shows the induction distribution with 50 amperes in field and 50 in series coil. In this case the effect of the series turns is to make the armature induction distribution practically uniform about the centre of the pole face.

Electricity In the Submarine Boat "Holland."

BY R. McA. LLOYD.

AT the present time the only practicable power for the propulsion of submarine boats is electricity, and if the boats are to have a considerable radius of action, the power must be carried in storage batteries.

The "Holland" and its principal features are now quite familiar to the public, and a complete description of her design and equipment is here unnecessary, but a few facts about her electrical apparatus may be of interest, particularly as it is the first of the kind and will doubtless be followed largely in future practice.

FIG. 1.—THE SUBMARINE BOAT "HOLLAND."

There will be various classes of submarine boats, including, for example, those that carry steam engines for surface running as well as for charging batteries; boats that have gasoline engines for the same purposes; boats that have in them no prime motors, but get their current for charging batteries from tenders or from plants on shore; besides other classes that will suggest themselves.

The "Holland" has a small gasoline engine and a large storage battery. The boat fully equipped weighs out of water about 75 tons. Of this 22½ tons is the weight of the storage battery. This consists of sixty cells built by the Electric Storage Battery Company especially for this purpose. They are installed in a lead lined compartment, and built substantially together, so that no ordinary amount of motion can injure them. The containing cells are light steel structures covered inside and out with sheet lead and lined inside with thin hard rubber. The cells are separated from each other by hard rubber and wood, and the plates are well protected by hard rubber separators. The plates are attached to and suspended from lead covered copper bars, which run from cell to cell, so that one positive and one negative are connected to each bar. These bars are further covered with hard rubber sleeves at the points where they rest

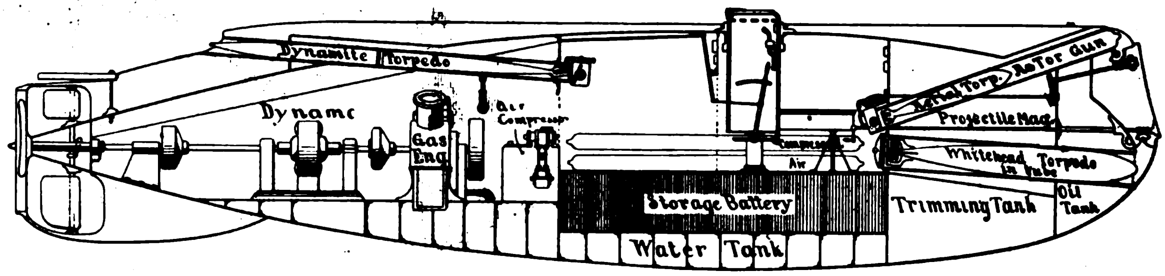

FIG. 2.—SECTION OF SUBMARINE BOAT "HOLLAND."

on the sides of the containing cells. This method of connecting the cells together permits of a great economy in room, besides great current capacity in the circuit.

The boat is well protected from damage by electrolysis, and the battery solution cannot spill unless the boat rolls or pitches 25 degrees, from a horizontal plane. The compartment is, however, drained and water which might accidentally get into it would not remain. It is also ventilated during the periods of charging by a suction blower, which draws the fumes from the battery compartment and drives them into the open air.

The battery may be discharged at 350 amperes for four hours, or at 700 amperes for one hour. When the battery is discharging at 350 amperes, the boat has a speed of 8 knots per hour, which is fast enough for submarine operations. When running on the surface the gasoline engine provides power for running at a 6 knot speed, and the boat carries enough fuel to drive her 1,000 miles. The engine is a 50 h. p. Otto marine gas engine and has proved very satisfactory.

The propeller shaft, dynamo and gas engine are so connected together by gears and clutches that the propeller may be driven either by the engine or electric motor, or by both, or he engine may simply drive the dynamo for charging the batteries. Of course, the dynamo and motor are the same machine in both cases. This machine was built by the Electro-Dynamic Company, of Philadelphia, especially for this work and is capable of developing 50 h. p. at 8 revolutions, or 150 h. p. at 1,200 revolutions. It weighs about 4,000 pounds and has a double wound armature with two commutators. The variations in speed are obtained first by combining the two armature windings in series, and including in the circuit a considerable resistance; second by the windings in series, and third by the windings in parallel. There is a controller of large capacity with a reversing attachment. The machine is shunt wound and when running as a generator may be varied from 120 to 160 volts by a large field rheostat.

There is a 10 h. p. motor for driving the air compressor and several small motors for yentilating and pumping. There is also a substantial switchboard and a complete electric lighting outfit.

A contemporary electrical journal editorially regrets that storage batteries are too heavy for submarine boats and suggests primary batteries, referring also to their advantage in the absence of fumes and gases and in freedom from spilling. These advantages are not easily discovered in the primary batteries known to electrical engineering, and are not as necessary as might be supposed from reading the editorial referred to. There is no difficulty whatever in carrying sufficient storage battery capacity for a whole day's operations, and if the boat is provided as is the "Holland" with a gasoline engine, the batteries may be recharged while the boat in on active duty. The "Holland" is in no way inconvenienced by gasing, as the battery compartment is thoroughly ventilated while charging is in progress and the boat on the surface. There is no spilling of acid because the cells are designed to prevent it, but if it should occur by any accident the compartment would be immediately drained into a lead receptacle from which the liquid would be pumped into the sea.

The interior of the "Holland" seems a little crowded, but that is to be expected in warships of all kinds. The entire battery is under the floor of the torpedo room, and can be examined by taking up sections of this floor.

For surface running the gas engine is used ordinarily, and the boat with its tiny conning tower is a dangerous antagonist even in this position, and is good for a thousand miles, but it is only a moment's work to shut down the gas engine and with electric power dive to a safe depth and run forty or fifty miles. With fifteen feet of water above her conning tower, there is little daylight available, but there is plenty of electric light, and plenty of air stored in the compressed air tanks. She carries a Whitehead torpedo always ready for a hostile ship, and dynamite shells for throwing into the enemy's forts. She has within the past few weeks demonstrated her ability to do all of these things, and has performed in New York harbor before many witnesses. She has not only kept her bearings under water for a mile but has run a number of consecutive miles, coming to the surface for a moment's observation at the end of each mile. She has bumped on many an oyster bed without injury to herself and has floated serenely in a heavy sea without discomfort to her crew. We are indebted to the "Scientific American" for the sectional view.

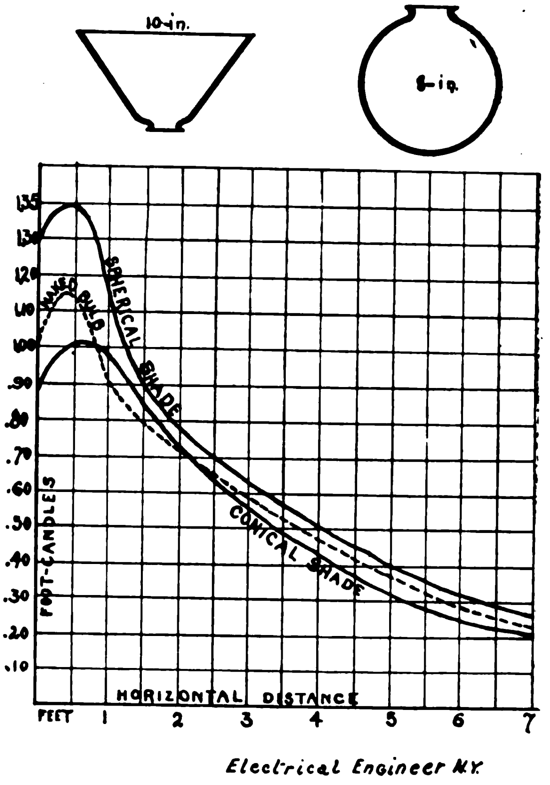
ELECTRIC LIGHTING

Conical and Spherical Shades.

BY I. C. THOMPSON.

SINCE the note published in The Electrical Engineer of March 17, further tests have been made for the purpose of comparing plain conical with spherical shades used with 16 c. p. incandescent bulbs under similar conditions to those in the previous experiments, and in the same room. The results obtained at different times are plotted in the accompanying curves. The shades are drawn to scale except as to thickness of glass, the 8-inch spherical one being of clear glass ground on the inside, while the conical shade was tested in the position shown while holding a 16 c. p. lamp; this shade was of opal glass of average thickness.

Upon comparing these curves it will at once be seen that the horizontal illumination curves follow about the same law beyond 2 feet measured horizontally from the light source. The spherical shade gives higher results, probably by reason of inside top reflection, the bulb being located in the upper part of the shade, and less light going into the ceiling than one would suppose. The naked bulb lies very little below it, while the opal shade, by reason of its higher percentage of absorption, naturally gives less illumination. This would indicate that unless the ceiling is



COMPARISON OF PLAIN, CONICAL AND SPHERICAL SHADES.

a very good reflector of light, very little of the luminous effect of the light refleeted upward from the inverted shade would reach the floor.

The effect of the reflection powers of various colors and characters of surfaces is not sufficiently appreciated. Where the lighting is of necessity economical, it makes a great difference whether the ceiling walls and furniture reflect 50 per cent. or whether they reflect 10 per cent. of the light they receive. Offices, workshops, school rooms, lecture halls, etc., therefore, should be finished in the lighter and warmer colors in order that a minimum of light may be necessary for their proper illumination. The following list of colors with the respective reflective properties will make this point clear:

PERCENTAGE OF LIGHT REFLECTED FROM VARIOUS SURFACES.

	Per cent.
Black velvet (Sumptner)	0.4
Black cloth	1.2
Deep chocolate (Sumptner)	4.0
Black paper (Rood and Tufts)	4.5
Dark blue (Tufts)	6.5
Dark green (Tufts)	10.1
Dark brown (Sumptner)	13.0
Bright red (Tufts)	16.2
Dirty yellow (Sumptner)	20.0
Dark brown (Tufts)	23.2
White sandstone (O'Conner)	24.0
Blue paper (Sumptner)	25.0
Yellow cardboard (Sumptner)	30.0
Straw yellow (Tufts)	34.4
Yellow paper or paint (Sumptner)	40.0
Green paper (Tufts)	46.5
Yellow paper (Tufts)	50.0
Gray paper (Tufts)	50.0
Light colored wood (Sumptner)	50.0
Bright yellow paper (Tufts)	50.3
Light orange paper (Tufts)	54.8
White paper (Atkinson)	70.0
Freshly fallen snow (Atkinson)	78.0
White-washed ceiling (Harrison)	80.0
Dead white (Hallock)	80.0
White blotting paper (Sumptner)	82.0
Mirror (Sautter)	83.0
White cardboard (Tufts)	92.3

The above figures show how important it is to select the proper tint or paper for a wall or ceiling. Not less important is the selection of shades. The diffusion of light, having for its object simply ease upon eyesight, considers but the area of the light source and its color. Thus with shades of the same size and color, that one should be selected which absorbs the least light during transmission. Data upon this subject is quite meagre. There does not seem to be any reason why the makers of these shades should not give the percentage absorption along with the description contained in their catalogues. This practice would no doubt lead to considerable improvement in diffusion globes and shades. In order to better illustrate the losses arising from the use of various shades, according to the several authorities quoted, the following list has been compiled:

PERCENTAGE ABSORPTION OF LIGHT BY VARIOUS SHADES.

	Per cent.
Clear glass (Stort)	6.0
Clear glass (O'Conner)	10.6
Clear glass (O'Conner)	12.0
Clear glass, engraved (O'Conner)	24.0
Clear glass, engraved, average (O'Conner)	35.0
Clear glass, engraved all over (O'Conner)	40.0
Flash coated globes (Stort)	11.0
Frosted glass, tulip (Lewes)	11.2
Ground glass (Lewes)	12.4
Frosted glass, pink (Lewes)	23.2
Ground glass (O'Conner)	29.5
Alabaster glass (Palaz)	15.0
Opal glass (Palaz)	20.0
Opal glass, pink (Lewes)	34.1
Opal glass, milky (Palaz)	30 to 60.0
Opal glass, smooth (O'Conner)	52.8
Opal glass, ground (O'Conner)	55.8
Opal glass, white (O'Conner)	60.0
Opal glass, colored (O'Conner)	64.0

It must be also remembered that absorption varies directly with the opacity of a shade, and therefore with its thickness, the degree of milkiness, or the extent to which it is ground or tinted.

Of the two shades used in these tests the spherical is decidedly the more ornamental and gives a light having a rich alabaster effect. Many so-called opal globes have a slightly yellow tint which is pleasant to the eyes and has a warm effect, but they absorb considerably more light. Engraved or ornamented clear glass which permits any rays to penetrate the eye direct from the incandescent filament, is but a half-way measure and should be considered as such. In general it is far better to have a naked light enclosed by a translucent shade in a light tinted room, both having a low percentage of absorption, than it is to have the same light in a clear glass shade toned down by dark walls and furniture.

It is good luminous effect we are after, and if we can secure at the same time ornamental effects, so much the better. Holophane globes afford an economical and brilliant light, but it must be observed that they simply cut one large light source into many small ones, each of which is still quite bright. The effect is brilliant, not soft. Nevertheless, where brilliancy is desired for display purposes, they do very well, but are not so well adapted for room lighting.

Mr. R. Richards, an English authority, has given some figures which may be of interest as regards the quantity of light in foot candles which is necessary for various purposes. Among them are: House lighting: general, corridors, halls, etc., 0.4; living rooms, 0.5; bedrooms, library, study, 0.25; table lighting, 2; this does not include reading, sewing, etc. Workshops: general illumination, 0.2; benches, 3.3; optical or fine work, 5. Public halls: general lighting and auditoriums of theatres, 0.33. Churches: general lighting, 0.25; pews and pulpit, 2. to 3.5. Street lighting, 0.10 to 0.12. These figures vary somewhat from those of other authorities, for here as elsewhere, the doctors seem to disagree.

Use of the Enclosed Arc Lamp in Textile Mills.

TEXTILE manufacturers throughout the country for many years have been carrying on experiments in their endeavor to secure an artificial light which would enable their operatives to work with the same facility as in actual daylight, and to produce material in the dark winter days not less perfect than that made in the full light of summer. Gas has long been discarded by the progressive manufacturer as an inadequate and unsatisfactory illuminant, and even the introduction of the Welsbach has had little or no effect in bringing gas back into favor. The necessity of a light which will not falsify colors to the eye and not injuriously affect it, precludes the use of even the most recent types of improved gas burners.

The series arc lamp of the type commonly used to illuminate the city streets has been, and even is now, in use in many mills. This lamp with a clear globe, as generally used, has been found too glaring and penetrating, and while giving a large quantity of light, has proved inconvenient and unsuitable on account of the uneven diffusion of the light, the creation of heavy shadows and the necessity of changing the carbons daily. The inverted arc lamp with the inverted umbrella-shaped reflector has also been tried, and while the results have been fair, the combination of the large reflector and the lamp is cumbersome and objectionable in appearance, while the necessity of keeping walls and ceilings constantly white is expensive.

The advent of the enclosed arc lamp has, for the first time, given the textile manufacturer a means of illumination which overcomes almost all the different objections and is peculiarly adapted for all classes of mill work. In this lamp the two carbons burn in a small glass receptacle held between the sides of the frame and completely surrounded by the outer globe. The outside air is excluded from the arc by the interior glass receptacle, and thus the carbons burn from 100 to 150 hours without renewal. The light is extremely brilliant and is softened and thoroughly diffused by using globes of opalescent glass of varying degrees of translucency.

Arc lamps of this type, known as enclosed arc lamps, were first developed for direct current and have come largely into use. They have recently been perfected by the General Electric Company for use on alternating current circuits also, and may, therefore, be used either in mills already furnished with their own direct current or alternating current dynamos or taking electricity from systems used to light the city streets.

Enclosed arc lamps have already proved satisfactory illuminants in mill rooms, where spooling, skeining, sorting and other delicate work is carried on, as well as in the stock-rooms, dye-houses, etc. The quality and intensity of the light for different requirements and classes of work being susceptible of regulation and variation by the use of different translucent globes, an almost ideal light is obtainable, as nearly like that of day as is possible with artificial light. The light from the arc, instead of being concentrated and glaring, is perfectly diffused, eliminating all heavy shadows and allowing of results which could not be obtained by any other artificial means of illumination.

The advantages which the enclosed arc lamp offers will readily be appreciated by mill owners and mill operators. The carbons burn for a long time, and a small number only is required, and the labor of trimming is very small. It is not necessary, therefore, to have a special man occupied solely in trimming arc lamps during the day.

The direct current enclosed arc lamp burns for about 150 hours with one trimming, that for alternating current about 100 hours. In certain mills where these lamps have been installed

the light is seldom used in summer, and in winter only a few hours daily; under these conditions re-carboning is necessary only about twice a year, while the cost of carbons is about five cents. Of course, in other mills where artificial light is necessary for longer periods during dark days or into the night, re-carboning is necessarily more frequent, but compared with open arc lamps, the cost of attendance is very small, while that for carbons shows a marked economy. With open arc lamps a large amount of carbon dust collects in the globe; thus when the globe is cleaned or dusted out by the trimmer the dust usually settles over everything that may be in the vicinity. With the enclosed arc lamp there is little or no dust, the combustion being almost perfect, and any that may be is collected in the small receptacle and held, as it were, in a bottle to be emptied where it cannot settle on any material or into machinery.

LETTERS TO THE EDITOR

Patents on Self-Oiling Engines.

On page 487 of your May 5 issue under Legal Notes there is an article relating to a decision made against us in favor of the Fisher Foundry and Machine Company. In reference to the matter we beg to state that such a decision was made in favor of the Fisher Company by Acting Examiner Jones. We immediately appealed the case and such an appeal was granted, and a hearing is set for June 17.

Since the decision was made by Acting Examiner Jones it has been ascertained that he had some doubts about glands and that he consulted others in making his decision. This decision, of course, as you well know is therefore void, and on these facts an appeal has been granted. Further we beg to state that the Imperial engine is covered by many patents, and there is not any question at all but at the next hearing the decision will be reversed and decided in our favor.

WESTON ENGINE COMPANY,

LITERATURE

TRANSFORMER DESIGN. By George Adams. New York, 1897. Spon & Chamberlain. 70 pp. 4¾ x 7 inches. Cloth. Price, $1.50.

This book forms a valuable addition to the literature of the transformer largely because it presents the problem of transformer design in such concrete form that it should be an easy matter for the reader to pass from the theory to constructive practice. On the other hand, some of the statements made may prove rather misleading, and the book can hardly be said to cover the subject fully.

On page 2, for instance, regulation is omitted from the list of objects to be kept in view when designing a transformer, whereas it is generally considered one of the most essential features of good modern apparatus. Likewise we find no mention of transformers for use with polyphase currents, concerning which the need for information is greater than of the simple transformer, and which might properly be expected to find a place under the broad title of "Transformer Design." Similarly, the subjects of mechanical construction, oil insulation, cooling arrangements and so forth have been scarcely touched upon, although the author may not have considered these to fall within the scope of the work. They would, nevertheless, prove welcome additions to a second edition.

A statement calling for some criticism is found on page 12, in which the author says that the drop in secondary voltage at full load in excess of that accounted for by the resistance of the copper circuits is due to magnetic leakage. This was the opinion formerly held concerning this drop in secondary potential and it is found in most of the older textbooks; but more recent experiments have shown this view to be untenable. Actual measurements of magnetic leakage in transformers have demonstrated conclusively that of the drop in excess of the C R loss, only a very small proportion is due to magnetic leakage. What actually occurs may be readily understood by considering the physical actions and reactions in the transformer, points upon which this little book touches only lightly.

The primary of a transformer has a given resistance upon which a comparatively high alternating voltage is impressed. Obviously an enormous current would flow through the primary winding, were not the impressed electromotive force opposed by a counter electromotive force nearly as great, generated by the alternating flux in the iron core. The difference between the primary and counter electromotive forces is a small quantity, hence the current flowing through the primary is also low and proportional to it. Precisely similar phenomena, as already pointed out, take place in the armature of a direct current shunt motor revolving free.

It will be seen that since the primary e. m. f., as well as the phase difference between primary and counter e. m. f., remains practically constant at all times, the only way in which more current can pass through the primary coil is by a decrease in the counter e. m. f. But the counter e. m. f., like the secondary e. m. f., depends only on the flux in the core, which must then decrease with load in order to effect the lowering of counter electromotive force which permits an increased current to flow through the primary. Experiments prove that this diminution of flux throughout the entire core, results from the phases of the primary and secondary currents coming more into step which, since one has a positive and the other a negative value, decreases the resultant magnetizing effect on, and therefore flux in, the core. Failure to understand this principle may lead the designer to adopt costly devices to change the shape and position of the winding as well as the shape of the core, in the hope of overcoming an apparent magnetic leakage which, in reality, does not exist.

In other parts of this book, some excellent formulas for design are given, illustrated by numerous curves and tables which show just where to begin, in preparing a new design, and how to proceed. Of course, the figures of manufacturing expense as well as the determining element in the design are meant to serve only as examples and must be varied either to suit American practice or whatever condition is determined upon as the most important in each case. And here it should be said that our practice has been somewhat overlooked in this book, at least in so far as there is little or no mention of the results attained in recent years by several American companies in increasing the all-day efficiency and improving the regulation. Nor has the effect of age on the iron of the core been taken up, although the larger manufacturers on this side of the Atlantic have given the matter much attention with a view to overcoming the increased iron loss that results with time.

A novel form of core plate has been suggested by the author on page 28, which seems to have the advantage of slipping easily over the formed coils without introducing any additional air gap in the magnetic circuit.

On the whole this book will repay careful study, and cannot fail to prove useful to a large number of students and engineers.

JOSEPH BIJUR.

Origanization of the Bolton Falls Electric Co.

The Bolton Falls Electric Company has recently been organized to develop the Bolton Falls, 4½ miles north of Waterbury, on the Winooski River. The river at this place falls 46 feet and the power is estimated at 3,000 h. p. The company is now asking for estimates on water wheels, penstocks, construction of dam and electrical equipment. The dam is 46 feet high by 120 feet long. Plans and all information can be obtained from G. H. Almon, manager, Montpelier, Vt. The directors of the company are C. L. McMahon, Stowe, Vt.; G. H. Almon, Montpelier, Vt.; G. E. Moody, Waterbury, Vt.; C. C. Warren, Waterbury, Vt.; G. W. Randall, Waterbury, Vt. The officers are G. E. Moody, president; C. C. Warren, vice-president; C. L. McMahon, treasurer; G. H. Almon, manager; C. D. Robinson, clerk. The power is to be used by the Mt. Mansfield Electric Railway, Vermont State Asylum for the Insane; Waterbury, Vt.; Waterbury Center, Vt.; Stowe, Vt.; Jonesville, Vt.; Richmond, Vt.

Vol. XXV. NEW YORK, MAY 12, 1898. No. 523.

At the Exhibition.

IF any of our readers have the opportunity to visit the Electrical Exhibition at Madison Square Garden and have not yet done so, we urge them strongly to go there as soon as they can. It is at once a beautiful and instructive spectacle, and those who know say that New York has never seen before so fine a display of machinery and scientific apparatus. There are many distinctive features of a purely popular or sensational interest, but the management has kept steadily in view two points, the sale of exhibited apparatus to those who now require it and the education of the greater public so that it in turn will join bodily the ranks of those to whom electricity has become an absolute necessity in every sphere and department of business and social life. It is not the least significant part of the whole matter that this altogether satisfactory exhibition should have been assembled at a time when after thirty years of peace the nation is straining every nerve to end quickly a righteous war. But the public realizes that electricity is perhaps our best weapon and wants to know what more may be expected from it.

Telegraphy in Warfare.

PROBABLY there was never a more striking demonstration of the value of electricity in warfare than the painful suspense we have all endured in waiting for the glorious news from Commodore Dewey. He cut the cable, but what a grand thing it would have been if he had had with him some good cable men who could have taken hold of the cut end and kept one of his ships in touch with the outer world. As a special dispatch from Washington well remarks: "The battle of Manila offers an illustration of the wisdom of having experts in telegraphy and electrical engineering attached to every army or fleet. It ought not to have been necessary to keep the world so long in ignorance of what Commodore Dewey had actually accomplished. If the electrical end of his establishment had been cared for as scrupulously as its strictly fighting end, he could have made his victory even more complete in its moral effect by showing the Spaniards the hopelessness of a war against so ingenious a people as ours." There is one brilliant electrical engineer with the Dewey fleet, Lieut. B. A. Fiske, but he is helpless while the cable lies at the bottom in deep water, for of all the ticklish things to hold and raise a heavy cable is about the worst.

In other ways the importance of electricity is being pointed out by this war with Spain, and we look for many developments tending to raise the level of the electrical work in the army and navy. Besides, new ideas will fructify rapidly. Take for example the illustration of the use of wireless telegraphy at Madison Square Garden, where both Cuban dynamite guns and submarine mines are fired off by that agency. From the small scale to the large is easy in this instance, and the ability to dispense with intervening wires is an enormous gain. The one difficulty that suggests itself to us is that of testing the distant circuit of the explosive apparatus, but there must be ways of meeting that point.

Meantime we are glad to note that telegraph and telephone are playing their part bravely, and that with such material as bimetallic wire bare circuits on wet grounds are proving extremely useful. Moreover, the phonograph is now seriously suggested as a safe and good means for sending dispatches. Let all these new things be tried, and many more. Some will fail, but many will work, and the nation that has them will be all the stronger in matters of offence and defence. Capt. Eugene Griffin has perhaps taken one of the best practical steps in his recent letter to the Secretary of War analyzing present conditions, with the result that a volunteer regiment of 750 volunteer engineers is being raised. The engineers' regiment will probably be used largely for coast defence and harbor work. It is the intention to have it representative of all branches of the profession, and it is to embrace civil, mechanical and electrical engineers, practical electricians, mechanics, artisans, draughtsmen and men familiar with all kinds of engineering work, all capable of being rapidly converted into military engineers with proper training.

In his letter to Secretary Alger Capt. Griffin pointed out that toward the close of the Civil War the engineer troops numbered about 5 per cent. of the strength of the armies, respectively, of Grant, Sherman, Thomas and Meade. The character of the country in Cuba and the probability of siege operations against Havana, he thinks, make necessary an unusually large proportion of engineer troops with the army of occupation. The proposed engineer brigade, he adds, like the engineer troops of all armies, would be armed and drilled as infantry, and would be quite ready to take its place in the line of battle in case of necessity.

Electricity on the Broadway Line, New York.

FOR many years Broadway was sacred against the invasion of the street cars. It is true that stages both spectacular and dingy haunted the thoroughfare through a long period, but the mere suggestion of tracks was anathema. But the growth of business and pressure of travel made a street car line desirable and inevitable, and after a lot of talk about an underground road, the famous "grab" was made by Jacob Sharp and his political crew, and the regime of the horse car began. This proved so successful that the cable came, although electricians all insisted that it was a mistake not to look a little bit ahead and put in electric traction. The cable has done its work fairly well, but can no longer hold its own against the brilliant demon-

stration that the electric underrunning trolley conduit system is now making on Madison, Lenox, Amsterdam avenues and on West One Hundred and Sixteenth street. The news is now given out that consents are being very freely granted by the owners of property along Broadway for the change to electricity, and that the General Electric Co. has the order for the equipment, which will correspond with that on other lines. As Mr. J. D. Crimmins says: "Electricity is preferable to the cable for many reasons, as patrons of the lines know. There is less shock in starting and stopping, less liability to stalling; and it is more economical. On account of its manifold advantages it will be but a short time until the underground electric system will supersede the cable as the cable has superseded the horse." This prophecy is already so far along in fulfilment that there is already relatively little cable road left in the United States.

Vacuum Tube Lighting.

ELECTRICAL engineers as well as laymen find the subject of electric illumination still as absorbing a topic as it was some twenty years ago. At that time the arc and incandescent lamp were prominently before the public, and many looked upon them with the eyes of skeptics, among the most pronounced unbelievers being many prominent electricians themselves. But arc and incandescent lighting passed through the ordeal and stand to-day far and away ahead of all of their competitors. We may be mistaken in our view of the situation, but it seems to us that the present period parallels in a marked manner the conditions which existed at the time mentioned above, and which are now applicable to vacuum tube lighting. Up to within a quite recent period vacuum tube lighting has been a thing of the laboratory, to which many eminent inventors have given their thought and energy. The reduction of the system to a fairly practical basis was the work which Mr. Moore set before him and the first fruits of which were shown at the Electrical Exhibition of 1896. That demonstration, crude as it was, we believe was enough to have indicated to the unbiased mind that there was "something in it." That Mr. Moore evidently thought so is shown by the fact that since then he has kept at it without the slightest let-up, with the result that he is to-day able to show what few would have thought possible a short while ago.

A description of the lighting of the Moore chapel at the Exhibition, which appears elsewhere in this number, seems to us, therefore, worthy of more than passing notice. This chapel, we firmly believe will be the forerunner of many vacuum tube light installations, both private and public. As to the practicability of the system as installed at the Exhibition, there seems to be but little doubt. Mr. Moore has worked out his details with much cleverness, and when one contemplates a structure lit continuously for hours at a time without a break by means conforming to the present standard system of wiring, including interior conduits, one is bound to admit that vacuum tube lighting is a factor that must be dealt with seriously, whether we will or not. By this we do not mean to imply that Mr. Moore's system has been brought to a stage beyond which improvement is no longer possible. To maintain this would be equivalent to saying that the incandescent or arc system of lighting were no longer capable of improvement. It is certain, however, that Mr. Moore's system at the present is at least in as perfect a condition as was the arc lamp in 1876 and the incandescent lamp in 1880, while we are not so sure but that it is even now in better condition for practical work than the other systems were at the period mentioned. Considering that Mr. Moore has tackled the practical problem single-handed he is unquestionably entitled to great credit, which we believe will be accorded to him by those inventors who know what it means to develop an idea involving so many considerations to a successful realization in so short a time, and with far from unlimited means at his command. We congratulate Mr. Moore on the genuine progress shown by him, and trust that he will persevere in his pioneer work.

An Interesting Non-Municipal Street Lamp Report.

THE average reports of city lighting committees are not absorbingly interesting documents, but once in a while we come across one that gives us some real information. An example of such is the 1897 report of the Committee on Lamps of the city of New Haven, Conn., just issued. As the lighting of this city is in most intelligent hands a closer inspection of this report will prove of value to lighting committees and central stations as well. New Haven is lighted by three systems, gas, naphtha and electric; there being 442 arc lights, 105 Welsbach, 633 plain gas and 512 naphtha lamps. All lighting is done by contract with private companies. The city is now paying $98.55 per arc light of 1,200 c. p., the electric lights being lighted at dusk and extinguished at dawn every night in the year, thus covering 4,000 hours of burning. Regarding the question of complaints due to outages, etc., we notice that from these various causes gas gave rise to 1,168 complaints, naphtha 709, electric lights 401. Quite a marked percentage of these complaints were due to the effect of a high wind last November, in which, however, the electric light showed up remarkably well. While none of these were out or broken, the Welsbachs showed one out, plain gas showed eight out and one broken, while naphtha showed 77 out, for that one night. During the whole year 278 lamps were reported out at various times, of which 50 occurred in a single night during February, 1897, when one of the circuits was broken by a falling tree during an extraordinarily high wind. Considering that the total number of electric lamps is 442 burning every night, and that only 278 lamps were reported out during the entire year, the record is a very good one. That the service must have been excellent is strongly evidenced by the fact that the entire amount deducted during 1897 from the bills of the electric light contractors was only $21.33.

In his very able comments on the figures presented, Mr. Henry Hopkins, Superintendent of Street Lighting of New Haven, states that the service rendered by the electric lighting contractors has been of a high grade. Mr. Hopkins also has something to say on municipal ownership of electric lighting plants, and as we believe his motives will not be questioned by any one who has followed his career, his opinion is worth recording. Mr. Hopkins says: "From what data and facts I have been able to obtain on both sides of the subject, I would say, that until the time comes when more information and accurate facts can be obtained, it would not be good business policy to enter into any such project. The recent showing up of the Philadelphia Municipal Gas Works amply sustains my belief, and ardent supporters of municipal ownership must have received a severe shock. And it is only one of many cases that could be quoted." Coming from a city official, this is a most encouraging sign that there are still many clearheaded men in municipal employ in this country.

TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work—IX.

BY A. E. DOBBS.

HOW TO CROSS CONNECT ON TERMINAL POLES, ETC.

Some linemen, in running the cross connecting wires on a pole—as from a cable box or changing the position of line wires—like to tie and lash them all together with twine or tape till they have a cable as smooth and stiff as a new rope. Now, this makes very neat looking work, but it is sometimes quite a bother in more ways than one. In the first place, suppose it becomes necessary to change a conductor, as is often the case. To do this the lashing must all be untied, or cut, leaving the whole mass in a disordered condition, and once in this condition it is apt to be left so.

Again, with the wires bound tightly together the insulation is

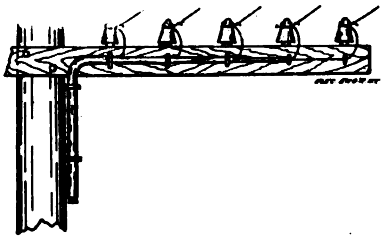

FIG. 32.

lower, and sometimes breaks down altogether, to say nothing of its retaining moisture after a rainstorm, and glueing together in hot weather. When it is necessary for wires to be bunched, the more loosely they lie together and the more free air surrounding them, the better the insulation will be.

The best way to do such work is to run the wires in such a way that each individual one can be traced out, pulled out, or inspected, and Fig. 32 shows such a method. First, on the pole and on the arm next to the pole drive gas-pipe staples, at distances of 12 inches apart, and pass the wires through them. One of these staples will hold 50 wires without crowding very much, or if more than 50 wires are required, larger pipe straps wound with tape will answer; but two rows of staples, one for each side of the pole, will accommodate 100 wires easily, unless the insulation is very heavy. When the arm is reached, drive one staple on the side of the arm, under each pin; and for the three outside pins, galvanized fence wire inch-and-a-quarter staples will hold three or four wires, and are therefore large enough. Where double arms are used, keep the staples on the inside, where they will be out of the way.

Never run the wire across the top of the arm, except at the insulator pin, as otherwise it will be trampled on, and the insulation worn off and perhaps broken.

Most linemen like to take a turn or two of the wire around the insulator, as in that way they have some slack wire if they need it, or enough to make another connection if broken or changed. It is best not to make this connection directly on the line wire. Instead, when the line wire is fastened to the glass, leave an inch of the end stick out, and when the copper wire is brought up, fasten and solder to this end; and turn it down alongside of the insulator. By so doing the line will not be weakened by rust at this particular spot, as is often the case. Some construction men use a connector, like a battery connector, at this spot; don't do it, it will make trouble.

Wire for this kind of work should not be smaller than No. 19, and either triple braided weatherproof, or rubber covered and braided. Never use office or annunciator wire for outside work.

TREE TRIMMING.

One of the greatest annoyances to the telephone man are trees, especially as permission to trim them cannot always be obtained. The use of insulated wire does very little good, as the insulation is soon worn off. Where there are 20 or more wires it is generally cheaper to run a cable low enough to pass under the heavy limbs, with junction boxes at 500-foot intervals, for local distribution. In this way, more than one arm will not be necessary.

When trees have to be trimmed, do not be satisfied with lopping off the twigs and ends of the branches, for next year the tree will be as bad as ever, and besides, its appearance is anything but artistic. Send a man up and cut the branch off close to the trunk and cover the end with paint, and it will make no further trouble. Many a time the tree can be trimmed so as to not only clear the lines, but look as well as before.

CABLES.

While it is taken for granted that cables will be used from the office to the different leads, they are also, many times, a necessary part of pole line construction. While not affording as good insulation as ærial lines they are more sightly and convenient than an equal number of bare wires could possibly be, and they also reduce the trouble account very materially; are not influenced by wind nor often by sleet storms and once properly put up and tested out make no further trouble till they wear out, which generally takes a long time.

On streets where trees are numerous and troublesome the only satisfactory service for a large number of wires is cable service, with distribution boxes at places most convenient, and with only one or two arms on the poles, for local distribution. One case we can recall especially where 14 or 15 arms were replaced by a cable of 204 wires is worth mentioning:

The cable was run out nearly half a mile from the office, till the distributing centre was reached and a great many wires were taken off, when it changed to a cable of 102 wires, and about a mile from the office was replaced by one of 52 wires when the suburbs were reached and the rest strung out with wires in the usual way. At every second corner the cable was looped into a terminal and both conductor ends brought to, and united at the terminal posts, as shown in Fig. 33. Thus every conductor could be found and if need be tested and used at each box. (In some cases of this kind a certain number of pairs only are taken into the terminal posts, say, from 1 to 20 at the first box, 21 to 40 at the next, and so on; but the best plan is to bring them all in, where they can be used for party lines if necessary, or tested back, in case of an "open," or even cut out in case of a "ground" beyond the box.)

Previous to this the service on this particular lead had been

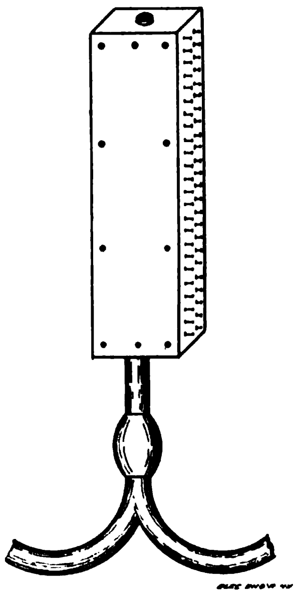

FIG. 33.

anything but an ideal one, but with the cable it seemed to leave nothing to be desired. We have seen cables run through residence streets suspended to trees with a short pole used occasionally to help out the distribution, thus carrying from 30 to 50 wires in places where pole line work would have been impossible. Here is a hint for our electric lighting friends. In many places such as this, a duplex lead covered cable would give better service than the flimsy insulation that is much used on overhead line wires at present. Trees and light limbs then need not be feared, and much three trimming and other troubles be avoided. While there are many different makes of cables, there are only three kinds in general use.

In some, and the earliest forms, the conductors are covered with rubber or gutta-percha compounds, such as Okonite or Kerite.

These furnish good insulation and are much preferred in telepragh, or electric light work, but they are not the best for telephone work generally, because their electrostatic and inductive capacity throws in retardation and cross talk. They should therefore be used only in short lengths though the objection to them is sometimes partially met by wrapping each separate pair (nearly all cable conductors are twisted in pairs) with tin or lead foil which is grounded in the office or to the common return.

Lightness, flexibility, and ease of handling are the desirable features of this class of cables.

Another of the older methods of insulation consists of cotton or jute thread soaked in either asphaltum, Ozite, paraffine or creosote, protected by lead armor which shields the conductors against outside induction. This lead armor is also grounded in the office or sometimes takes the place of the common return, its bulk making its resistance negligible. Last, but not least, we have paper either dry or paraffined and lead covered. The best insulation for electrical conductors is dry air, and a special kiln dried fibrous paper furnishes the nearest approach to air at anything like reasonable cost.

But while dry paper is the best, it is also a source of weakness, for it will absorb dampness very rapidly if exposed. To prevent this, the ends for a few feet back are generally filled with pitch or paraffine, sometimes hardened with rosin, or beeswax, to prevent absorption of moisture when the cable is opened.

In some cases, however, where there is a great deal of underground work, and the work of handling cables is well understood, these compounds are left out even at the ends, the joints or terminals being quickly put on and paraffine poured over the joints only, to drive out the trifling amount of moisture that may have accumulated. But the body of the cable being simply kiln dried paper, it is easily seen that a very slight puncture in the lead covering means dampness and low insulation. And let us say right here that when a cable has been left open an hour or so, and boiling hot paraffine poured into it, the bubbles arising in the liquid will show that some moisture has been absorbed, even on a very dry day.

Persons not familiar with cable work, had best not undertake to put up a very large amount of it, and it would probably be cheaper in the long run to arrange with the manufacturers to send some one to supervise the work, unless certain that the force on hand can manage it. In New York City it is usual to let the contract to the cable company direct and require a thirty days' test, the tests being carefully made and severe.

Still a few hints on the subject may not be amiss.

Aerial cables cannot be handled too carefully. Don't forget this, or let the men forget it. Do not pull a lead cable over the arms and leave it hanging there, as certain farmers have been known to do; perhaps under the impression that they could treat it the same as if it were a trolley feeder.

As it does not improve a cable to have men tramping over it, try and keep it out of their way by putting it in places where they won't have to step on it in getting up and down the pole; put it far enough out to allow them to get by it, say, outside the nearest pin.

Keep a sharp lookout for punctures and instruct all hands to do the same. See that all nails, and cleats or anything liable to injure the cable are removed from the inside edge of the reel. Do not let the men open a cable out of doors—or indoors for that matter—after one o'clock, unless sure they can finish it that day, for a cable once unsealed should be finished and sealed again as quickly as possible. Once upon a time some men opened a cable to put on a terminal head at 4 o'clock p. m. At 6 o'clock it was not half finished, but they went home for the night, leaving the terminal uncovered, and slept the sleep of the just. Mist in the early part of the night; and a northeast rain and snow in the latter part, and a well soaked head. (A cable head is not benefited by a soaking even in ice water.) Several bad conductors, cross talk between every one of them, and more from the subscribers. And the man responsible for all this, with the nerve of a train robber, tried to get an extra discount from the company that furnished the cable on the ground that the cable was no good in the first place.

The first thing to be done before putting up a cable, is to hang the suspension wire. This may be as small as No. 6 for short spans or No. 4 for spans not exceeding 100 feet—that is, for 100 wire lead covered cable—but the best span wire is a manufactured cable composed of seven strands. These strands should not be smaller than No. 12, and for spans of 150 feet, seven strands of No. 10 is about right. Of course the terminal poles at each end of the cable must be guyed beyond the possibility of their giving way, for if not drawn tight the span wire will soon begin to sag under the weight of the cable, and while a sagging cable will probably give as good service as any, yet it has a disreputable look and work of this kind leads to a demand for underground construction. If the overhead work is all it should be, there will be no demand for underground work, except in the largest cities.

Do not try to pull out a 2,000 foot length of cable from one end and expect to have it free from trouble, as the strain on the cable will require a team of horses to draw it before it gets through. If thought desirable to draw out 2,000 feet in one piece, which is not advisable except by the most experienced men, place the reel at a point one-third the distance to the terminal pole, and when that is drawn out and suspended draw the rest off the reel, coiling it on the ground in the form of a figure 8 twenty or more feet across, this being done to prevent kinks. Then start the inside end back the other way. In some places the cable may be all laid out on the ground and the hangers put on there. Then raise the end to its position on the pole and a man in a boatswain's chair can follow the span wire and hook it on.

The chair may be suspended from a snatch block which travels over the span wire, the block being one that can be opened at the side and changed as the poles are reached. If the hangers are of a kind that can be readily put on by hand—as clip hangers —another snatch block carried on the span wire by its hook with the cable passing over the pulley and pulled ahead from the next pole will lift it up so the man in the chair can handle it, the chair being also pulled along. But the most common method is to have men enough to man each pole, put on the clips as they leave the reel, and as fast as they come up the man on the first pole hooks about every fourth or fifth one on the span wire and when the next pole is reached a man there unhooks them, passes them around the span wire support and hooks them on again, the same operation being repeated at every pole—note if malleable iron hooks or clips are used; they should be placed about 18 or 24 inches apart. As the last section is being pulled in, every hook is then placed on the wire so that when pulled through that part of the work is done.

Another method much in favor with some companies is to pull the cable through in snatch blocks placed every 50 feet apart and hung from the span wire afterwards, suspending it with marlin yarn or wire. In New York City marlin is used, in Brooklyn No. 14 steel wire. This is wound on with what is commonly called a spinning jenny; it consists of a hollow wooden cylinder split in two parts and large enough to cover the cable and span wire. It is brought together over both the cable and span wire and wound on the outside, with marlin enough to reach the next pole. The marlin end is then securely tied around the cable and span wire and the jenny rapidly pulled through to the next pole with a rope, the yarn slipping off as it is pulled along. At the next pole what remains of the yarn, or wire, is taken off and the operation repeated till all the cable is in place. It is claimed for this method that the cable lasts longer than when hangers are used.

In estimating the amount of cable required, always allow for a few feet extra at each end in order that it may be bent down the pole and brought up into the terminal box. It is also best to cut off two or three feet from each end, as that part of the cable is apt to be bad.

The cable should be brought into the box from the bottom, as also the connecting wires, in order to keep the inside of the box as dry as possible. The inside of the box should also be painted with either shellac, or asphaltum—P & B is one of the best asphaltum compounds for this purpose—for the same reason.

If the cable is a long one, ground strips and lightning arresters will be necessary, so that the box should be made large enough to include these.

The cable companies nearly always furnish compounds for filling the terminal head, but if this is not at hand a mixture of paraffine and beeswax will answer very well. Pour in boiling hot

Wires with connections inside the head should be soldered, as a general rule. There is a solder that is made up in thin hollow strips, with acid salts in the centre, that is best adapted for this work. As the wires will nearly always be found in twisted pairs, arrange to keep them together in regular order, so that the mate to any conductor can be found, when it becomes necessary to run metallic circuits.

Bell Telephone Output.

The American Bell Telephone Company's statement of the output of instruments for the month ended April 20 shows:

	1898.	1897.	
Gross output	29,254	20,426	Increase.... 8,828
Returned	13,139	7,245	Increase.... 5,894
Net output	16,125	13,181	Increase.... 2,944

From December 1 to April 20:

	1898.	1897.	
Gross output	109,921	73,735	Increase....36,186
Net output	58,224	45,579	Increase....12,645

This is a very heavy gain.

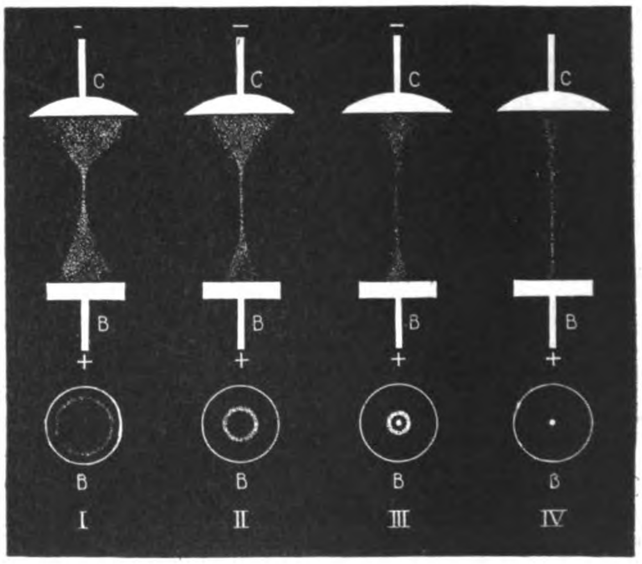
Adjustible X-Ray Tubes.[1]—I.

BY A. A. C. SWINTON.

THE Crookes's radiant matter tube, in some form or other, affords the only known means by which the Röntgen rays can be generated, and it is, therefore, perhaps not altogether inappropriate that the first ordinary paper communicated to the Röntgen Society should deal with the design of tubes of this description. As most of those who worked with the various forms of tubes originally employed for producing Röntgen rays will not readily forget, these had many imperfections, and there can be little question that the first real advance after the announcement of Röntgen's discovery, was Mr. Herbert Jackson's adaptation of Crookes's focus tube to X-ray purposes. The focus tube gives a quantity of X-rays not obtainable with the older forms. It is much less liable to be cracked or injured by the heat of the discharge, while as theX-rays all proceed from a very small area, a degree of sharpness is attained in the resulting screen-image, or photograph, that was previously quite unobtainable. The focus tube as originally introduced, though a vast advance on all previous arrangements, is not without its imperfections. Dr. MacIntyre was, I believe, among the first to call attention to the importance of using electric discharges of great electrical quantity in order to produce the best results. These heavy discharges give a much brighter screen, or what is the same thing, they enable photographs to be taken with much shorter exposures. They also cause the X-rays to be more penetrative, but at the same time they are very hard upon the tubes. With the focus tubes of the original form, heavy discharges will frequently twist up or even melt the platinum, and will usually make it red or white hot. This leads to blackening of the tubes, and to a gradual increase in the resistance, till eventually no discharge can be got to pass.

Recognizing these defects, I set myself some little time ago, in conjunction with Mr. J. C. M. Stanton and Mr. H. Tyson Wolff, the task of investigating the action of the focus tube, with the idea of, if possible, improving the design, so as to admit of heavy discharges being employed, with the view of obtaining easily and continuously the most active and penetrative X-rays possible. At the same time, seeing the great variation of the character of the X-rays that occurs with very small changes in the degree of exhaustion, and the practical difficulty of obviating such changes in practice, I endeavored to discover some ready method of adjustment more certain and more easily worked than the auxiliary pumps, potash tubes, and other similar appliances that had at that time been used or suggested for this purpose.

When a focus tube is carefully examined while under the process of exhaustion on the mercury pump, the form of the cathode discharge is found to alter from the initial appearance shown between the cathode C and the anti-cathode B, in Fig. 1, at a low vacuum, through the appearance shown in Figs. 2 and 3, to that illustrated in Fig. 4, which shows the appearance when the vacuum is high. As will be observed, the cones of cathode rays in each case converge from the cathode cup to a focus, and then diverge again on the other side of the focus to a less and less extent the higher the vacuum. Finally, at a high degree of exhaustion the cathode discharge does not appear to diverge again very perceptibly, at any rate within a moderate distance, but continues in a thin line. It is when this stage of exhaustion is reached that Röntgen rays are given off in their most active and most penetrative form. Experiments show that both the convergent and divergent cones of cathode rays are hollow, and not solid in section. When the concentrated cathode rays are allowed to fall upon a disc of ordinary electric light carbon, the latter exhibits surface luminescence. Except, however, when the disc is exactly at the focus, in which case it shows a bright luminous spot, the intersection of either cone by the disc gives not a solid spot of luminescence, but a hollow luminous ring, which decreases in diameter the higher the exhaustion, as shown in the lower portion of Figs. 1 to 4. It appears further that the cathode rays are not given off from the whole surface of the cathode cup, but only from a ring-shaped portion, the diameter of which is less and less the higher the exhaustion. This, perhaps, explains the reason why very large cathodes give no better results in producing X-rays than comparatively small cathodes. Indeed, at the degrees of vacuum necessary to produce penetra-



FIGS. 1, 2, 3 AND 4.

tive X-rays, the greater portion of a very large cathode is apparently ineffective, as the discharge seems to come off entirely from a very small part of the central portion. This is not readily seen with the usual cathode cups of aluminum, but with cups of carbon it is easily observed. Full details of the experiments from which the above facts are derived, will be found in "The Proceedings of the Royal Society," Vol. LXI., pages 79 to 95.

Cathode rays are generally believed in this country to consist of atoms or molecules of residual gas, which being similarly electrified to the cathode, are repelled by the latter, and travel at an average velocity not much less than one-twentieth that of light. It is obvious, however, that upon such a theory the precise average velocity must depend both upon the exact potential of the cathode and molecules at the moment the latter leave the former, and also upon the degree of exhaustion of the tube, upon which depends the free path of the molecules—that is to say, the distance a molecule can travel before coming in contact with another molecule. Years ago Crookes showed that the deflection of a cathode beam by a magnet depended upon the excitation of the cathode, and upon the degree of exhaustion—that is to say, the deflection was less the higher the velocity of the molecules. More recently Birkeland has produced what he calls "the cathode ray spectrum," from which it appears that the

[1]A paper read before the Röntgen Society, London.

cathode rays are not homogeneous but heterogeneous, some being more easily deflected than others, so that when the cathode stream, passed through a slit, is deflected by a magnetic field, and is then allowed to fall on the glass and cause fluorescence, the result is a series of bands. These bands are in a perpetual state of movement, and the conclusion is obvious that the molecules that form the cathode stream are not all moving at the same rate, but owing to the pulsatory and oscillatory nature of the electric discharge and the varying electrification of the cathode are divided up into groups, which have different velocities, and, being for this reason differently deflected, strike the glass and cause fluorescence in separately localized bands.

Now, as Prof. S. P. Thompson first pointed out, and as all who have since observed the effects produced on a fluorescent screen while a focus tube is in process of exhaustion, and is at the same time being excited, are aware there are several different stages as regards the X-rays produced. First of all, at less than a certain vacuum there are no X-rays; next, as the vacuum increases, X-rays show themselves, but of a quality that will do little more than penetrate the backing of the fluorescent screen. As the vacuum is further increased the rays become more penetrative and show the bones in the hand. Next a point is reached, when the flesh of the hand seems to be almost completely transparent, while the bones are almost entirely opaque; at still higher vacua, the bones becoming more and more transparent, the contrast between bones and flesh becomes less and less, till at length, at the very highest vacuum at which the discharge will pass, the bones scarcely show at all, owing to their having become almost as transparent as the flesh, and the whole hand throws but a very faint shadow on the screen.

Again, what I have termed the "penetrative value" of the rays is found to be dependent upon the applied electromotive force, that is to say, the difference of potential between the cathode and anode, and the conclusion seems to be irresistible that on the assumption that the cathode rays consist of rapidly moving molecules, which by bombardment of the anticathode cause X-rays to originate, that the penetrative value of the X-rays depends upon the velocity of these molecules at the moment they strike the anticathode, and to the difference of potential between molecule and anticathode at the moment of impact, or to one or other of these conditions.

I must again refer to Prof. S. P. Thompson's experiments as to the value of different materials for the anticathode, as he was, I believe, the first to discover that the higher the atomic weight of the material the better the result. Further experiment, however, shows that while what I may call the quantity of X-rays produced as measured in terms of the brightness of the fluorescent screen, or in inverse terms of the length of exposure necessary to impress to any given degree a photographic plate, is largely dependent upon the material of the anticathode being greatest with anticathodes of the highest atomic weight, the penetrative value of the rays—that is to say, their powers of penetrating opaque substances—is independent of the material of which the anticathode is constructed. For further particulars on this subject I may refer inquirers to "The Proceedings of the Royal Society," Vol. LXI., pages 222 to 226.

To come now to more practical matters, metallic uranium, which is the element with the highest atomic weight (240) is commercially unobtainable at present. It is to be hoped that this state of affairs will not continue, as in addition to uranium being probably the most efficient emitter of X-rays, it is also stated to have the great further advantage of not blackening the glass, even after prolonged use. Thorium (atomic weight 231) and thallium (203) being also commercially unknown, and bismuth (208), lead (206), mercury (199), and gold (197), being too easily fusible, platinum with an atomic weight of 194, and a very high fusing point, is the best obtainable material for the anticathode surface.

As platinum is, however, expensive, and thin sheets are apt, if unsupported, to be fused, pierced, or deformed under the bombardment and intense heat, I have found it desirable to mount the platinum disc on a larger and much thicker disc of cheaper metal, which not only supports and prevents mechanical deformation of the platinum, but also acts as a dissipator of heat, in addition to lessening the blackening of the glass, owing to there being only one platinum surface exposed.

In the tube I have now in my hand, which was the first constructed in my laboratory on this plan, the platinum is simply a piece of foil soldered with silver solder upon one side of a penny. Copper or bronze are, however, not good materials to introduce with a high vacuum tube, for as will be observed from this specimen, which has been a good deal used, they are apt, even more than platinum, to cause considerable blackening of the glass, and this blackening tends to increase the resistance of the tube to the electrical discharge.

A much better backing for the platinum is undoubtedly aluminum, but here the difficulty arises that it is very difficult, if not impossible, to solder platinum on to aluminum, and a good contact between the two metals is necessary. A simple plan, and one that has been found very efficacious, is to make the platinum in the form of a disc—say, about 0.4 inch diameter, and about 0.02 inch thick. The aluminum may be 1 inch diameter and 0.25 inch thick, and upon the face of it there is turned a shallow circular depression, just of sufficient diameter to receive the platinum, but rather deeper than the thickness of the latter. The platinum is tightly wedged into this depression, the edges of which are slightly rivetted over the platinum by hammering.

It has been thought by some that there is an advantage in making the anticathode and the anode of an X-ray tube separate, the idea being that in this case there is less blackening. This idea I believe to be erroneous, provided the surface of the electrode which performs both these functions is sufficient to prevent heating, and provided, as is always best, a small spark gap is introduced into the circuit so as to stop out entirely the make current of the induction coil or any reverse oscillation in the discharge which otherwise would during their continuance make the anticathode the cathode for the time being. There can be no doubt, however, both for the permanence of the vacuum and also for the prevention of blackening, of the importance of preventing the overheating of the anticathode, and though the mass of aluminum I use and recommend is very efficacious in this direction, I am of opinion that as more and more electrical power is employed in order to obtain better and better results, some other arrangement for taking away the heat—say, in the direction of water or mercury circulation through the anticathode—will be found advantageous.

As already mentioed, one of the results of a red or white hot anticathode is a rapid deposition of platinum and blackening on the glass. This finely-divided coating of platinum occludes the residual gas and causes the vacuum to become too high. Heating the glass will to some extent restore matters to their proper condition temporarily, but, apart from the degree of vacuum, the blackening seems also to have an effect in increasing the resistance of the tube, which is very probably analogous to what Crookes discovered when he found that a non-fluorescent coating on the inside of a tube increased the resistance of that tube to the passage of the electric discharge.

The precise distance between the cathode and the anticathode is not of great importance, provided the degree of exhaustion is suitable, and provided the anticathode is beyond the focal point at which the convergent cathode rays meet together at low exhaustions. It is well, however, not to fix the anticathode too far beyond the focus, as this necessitates a higher exhaustion in order to obtain penetrative X-rays, and as too great a distance also impairs the sharpness of the resulting image.

The distance between cathode and anticathode has, however, a considerable effect upon the resistance of the tube, and upon the character of the X-rays it generates. In fact, adjustable tubes with which X-rays of any desired penetrative power can be obtained at will without altering the degree of exhaustion, or in which the unavoidable variations of vacuum which are found to take place in practice, can easily be compensated for, can be arranged with a movable anticathode mounted on a sliding rod, so that the distance between cathode and anticathode can be varied by gently tapping the tube.

MR. H. M. SALMONY, senior partner and managing director of H. M. Salmony & Company, Limited, of London, is here to take up electrical specialties suitable for the English and Colonial markets. His chief object is to take over sole agencies for alternate current motors, enclosed arc lamps, etc. H. M. Salmony & Company, Limited, are one of the largest electrical supply firms of the United Kingdom; they do not install plants themselves, in order to avoid competition with contractors. As a consequence they have over 5,000 contractors as customers on their books. This firm is therefore in the best possible position to represent American firms whose object it is to get a large turnover. H. M. Salmony & Company, Limited, have their own works in Birmingham, where they make some electrical specialties and chiefly electroliers, brackets, bronzes, etc.

Events at the Electrical Exhibition.

The Bell Telephone Pole.

It was quite interesting to note throughout the past week how the big electrical exhibition at Madison Square Garden pulled itself together and each night became more brilliant and beautiful, until the spectacle which presented itself to the eyes of the thousands of visitors on Saturday evening was indeed lovely and perfect. Of course, even now there are little touches being given, but rather by way of enhancement than of necessity. One exhibitor is not quite pleased with the look of his space and goes in for more decoration, or his neighbor puts in some graceful palms. Several of the makers of heavy apparatus have brought in new pieces, seeing how large the attendance is and finding a very ready inquiry for prices from the visitors, the quality of the attendance being very high. That so fine an exhibition should have been made, and licked into shape in less than a week, speaks volumes for the energies and courage of those leading the work. With "strikes" innumerable and with the country engaged in war, it might seem that the burden was too great, but the general manager, Mr. Marcus Nathan, "the little Napoleon of the Show" emerges finely from the ordeal. The Garden authorities who have seen many exhibitions are very hearty in their praise of the manner in which this has been organized and on its superb appearance.

The Electrical Engineer last week presented several pages of copious notes on different exhibits, with plans of the two chief floors. This week it begins its series of illustrated and descriptive articles on the leading commercial exhibits, many of these being on a remarkable scale of expense and importance, as the pictures testify. But in the meantime a number of auxiliary features have been got into shape and are a centre of attraction for crowds. These are chiefly in the Concert Hall and Assembly Rooms, and include there the charming Moore chapel, the model third rail system, Mr. H. V. Parsell's galvanoplastic exhibit, the testing apparatus from the Brooklyn Polytechnic Institute and Dr. S. Sheldon; and the historical wax tableaux in a series of eight groups. All these features we shall take up, as without exception they deserve the highest encomiums. But there are other features of interest everywhere quite outside the commercial exhibits. The New York Electrical Society has a cosy booth in a commanding position, and displays proudly not only the golden key loaned by Gen. E. S. Greeley, and now used by both ex-President Cleveland and President McKinley, but also the telephonic-phonographic speech of Vice-President Hobart, so that every passer-by can hear it. Mrs. Hobart and young Master Hobart have both been to the Garden and listened to it again, as they were in Washington when the original was sent, and wanted to see how accurately the Edison phonograph had done its work.

Adjoining the Society booth, the "Theatrophone" is in full swing, being the telephonic service from the theatres handled by the New York Telephone Company. Multitudes gather around nightly to hear the songs, marches, applause, etc., and the various exhibitors in the Garden have already worked out a pretty accurate time table, of the leading specialties, and a general movement from inside the booths to the long board indicates that something good is just about to be on tap.

Down on the main floor again is the fascinating exhibit of the field of force on a huge scale, by Mr. E. T. Schoonmaker, of Fordham, N. Y., on a white painted sheet of plate glass about 5 feet by 3, and supplemented by a number of his matchless "spectra." Around the corner again on the main aisle is the Edison magnetic ore separator exhibit, with its dainty separator model at work in sharp contrast to the huge blocks of iron rock, six or seven tons in weight, which the Edison crushing machinery at the mines smashes to pieces at one blow, as thoroughly as Dewey did the Spanish fleet at Manila.

Off the main floor again up in the Arena Circle is the complete electric printing establishment used on the opening night to print the messages and now in regular demonstrative operation. Just by, to show that if the pen is mightier, there are other things doing good work for liberty, is the Sims-Dudley Cuban dynamite gun, which is here fired with smokeless powder, emits a menacing whisper and discharges little flags and wads of Manila paper. Near by again is Mr. W. J. Clarke's improved wireless telegraph apparatus, not only ringing bells, etc., clear across the vast hall, but blowing up the submarine mines that have been planted by Mayor H. J. Smith under the cruiser floating peacefully beneath the lofty ærial electric fountain.

At the far eastern end of the hall is a fine electric cascade that is expected to be in full working order this week. When it was held up by the strikes and drunkenness of the men working on it, young Mr. Edison pitched in with all his father's vigor and grit. Some defective work broke three of his fingers for him, but he stuck at it persistently in a way that evoked universal admiration, although he had to undergo a severe surgical operation and is seriously disabled.

Above all the exhibits in the centre of the main hall hangs the lovely McIntire "arcolier," a distinct creation in large illumination, and an object admired by everybody, technical and lay. It is so airy and graceful, one forgets the weight and the number of lamps and pendants it carries.

Down stairs in the basement is the very fine generating and steam plant elsewhere referred to, and this is supplemented by the Engineering Picture Gallery, which already includes about 300 fine pictures with others still coming in. It was certainly a happy idea thus to render attractive the long passageways to the plants in operation, and no little instruction is derived from the gallery by hosts of visitors.

The present week is a very busy one at the Garden, as a number of new features have been arranged, now that the main Exhibition is off the minds of the management. The New York Electrical Society is beginning its course of popular lectures with one by Dr. S. S. Wheeler, on one of the special topics of which that well known engineer is a recognized master. The Stationary Engineers also gather at the Garden as guests of the management and the society. The week begins also with the starting of an X-ray exhibit for all, by Mr. W. J. Clarke, and with War Bulletins from all the leading papers, handled by Mr. C. Chamberlain, the Press Agent of the Exhibition. On Friday and Saturday comes the great Telegraphic Tournament organized by Mr. Fred. Catlin and Mr. J. B. Taltavall. Other attractions are also in hand, of really bewildering variety and extent.

These notes for the week must not close without mention of the novel effect on the tower, in regard to which we cannot do better than quote the "Evening Post" as follows: "The tower of the Madison Square Garden has often presented a beautiful spectacle at night, but it was surely never more a vision of beauty than since the Electrical Exhibition opened. With apparatus and by means which the management refuses to disclose, the tower each evening after dark is thrown up against the sky with a multi-colored radiance that causes every eye to be turned upon it, not only in the adjacent streets, but across the ferries and out well into New Jersey, and the Connecticut suburbs. The name that is already commonly given to this popular performance is "Diana's skirt dance." It really seems to be a huge representation of the Loie Fuller effects, with the aid of the wind, and of colored screens and searchlights. In waving columns of steam and cloud, some diaphanous material coils and curves around the shaft of the tower, right up to the foot of Diana, and then the tinted fires of electricity are let loose on this ever-changing scenic effect. At one minute the tower is all the colors of the rainbow; the next it is

a pearly white or blue, and then again it is all bathed in blood red, while at the same time a keen searchlight is thrown on Diana herself, as she points to the wind. Just below, of course, hangs the electric sign of the show, suggesting the wondrous things that are going on within the Garden itself; and thus a piece of advertising not less beautiful than it is clever accomplishes its purpose."

The Steam and Electrical Plant of the Exhibition.

AFTER having satisfied himself to his heart's content as to the wonderful advancement made in the application of the electric current, the visitor to the exhibition naturally wants to see how the current is actually generated and distributed. In order to satisfy this desire on the part of the patrons of the exhibition, and to convince them of the rapid strides that have been made in the steam generating and consuming apparatus as well as all other types of engines, a complete steam and electrical plant is in operation in the basement of the Garden. Two Babcock and Wilcox boilers of 265 h. p. each, built for the new plant of the Metropolitan Street Railway Co., were selected to furnish all the steam used at the exposition. The boilers are of the forged steel construction and were built for 200 pounds working pressure. They are in charge of Mr. M. Dardis. These boilers are supplied with undergrate mechanical draft by means of the Beekman system. This system consists of a steam driven fan automatically controlled by the Beekman system of valves. The air is delivered through deflecting dampers in the bridge walls under the grates into the closed ash pits. The principal feature of the system is the automatic regulation which controls the speed of the fan by the steam pressure in the boiler. When the pressure in the boiler rises above a desired point, a 6 x 6 engine slows down gradually and reduces the supply of air and the amount of steam generated. This portion of the plant is in charge of Mr. R. T. Mickle. The question of boiler feed-water is fully as important as the coal supply. The water of New York city being exceptionally well adapted for boiler use, no filters or purifiers were considered necessary. The pumps supplying feed water to the boilers are of the Henry R. Worthington Co.'s make, who have a splendid exhibit on the main floor near the main entrance. The steam pressure on the boiler is indicated on steam gauges manufactured by the Ashcroft Mfg. Co., New York., who have a very handsome exhibit in conjunction with the Consolidated Safety Valve Co. and the Hayden & Derby Mfg. Co. The Consolidated Safety Valve Co. are exhibiting "Richardson-Ashcroft" nickel seated pop valves, consolidated brass seated pop valves, farm engine, water relief, encased locomotive, muffler and side outlet valves and valves for marine use. The pop valves used on the boilers at the exhibition were furnished by this company. The Ashcroft Manufacturing Co. are exhibiting pressure and vacuum gauges of all kinds, Edison recording gauges, "Tabor" steam engine indicators, Coffin averagers, Moscrop speed recorders, genuine Packer ratchets, malleable iron stocks and dies, revolution counters, inspectors' test pumps and gauges, and gas proving test pumps and gauges. The Hayden & Derby Mfg. Co. are exhibiting the Metropolitan automatic, double tube and locomotive injectors, "H-D" ejectors, drive well ejectors, water heaters and strainers. The water supply for the boilers which furnish the power at this exhibition is furnished by one of this company's No. 14½ Metropolitan double tube injectors. The three exhibits are in charge of Messrs. Milton A. Hudson and Frank Andrews.

A description of this very modern steam plant would be incomplete without a mention of the fuel economizers which of late years have played so important a part in an up-to-date and efficient boiler plant. The Fuel Economizer Company, of Matteawan, N. Y., are exhibiting in actual operation a Green fuel economizer suitable for a 300 h. p. boiler. The scrapers are moved by a ¼ h. p. motor, which is claimed to be quite an improvement over the engine drive. The exhibit is in charge of Messrs. Wm. Downs, the New York representative, and Messrs. P. J. Challen and A. H. Blackburn from the main office and works at Matteawan, N. Y. Another interesting fuel economizer exhibit is that of Broomell, Schmidt & Co., Ltd., York, Pa. It consists of a 400 h. p. American fuel economizer 10 x 6 x 12 feet. It weighs 30,000 pounds and contains 98 tubes 4¾ in. x 9 ft. It is supplied with Broomell's improved engine driven scraping device, which is easily accessible and insures a close rubbing. There is a constant forced circulation of water through the heater. The exhibit is in charge of Messrs. H. Von Mengrenhausen, M. E. and A. P. Broomell.

The majority of the engines exhibited are direct connected to generators and comprise a great variety of types and sizes. Beginning nearest the boilers we find an American Ball engine, direct connected to a 25 kilowatt generator, built by the American Engine Co., and one 5 h. p. multipolar motor. A neat switchboard equipped with switches, measuring instruments and rheostat completes the exhibit, which is in charge of Mr. Jos. Englesby. The New York Safety Steam Power Co. are showing a 13 x 12 vertical automatic cut-off heavy duty engine with automatic lubrication, direct connected to a Fort Wayne generator. Then follow in the order given a 13 x 12 in. Armington and Sims engine, direct connected to a Walker generator; a 125 h. p. Fischer tandem compound, four-valve, automatic, high speed, self-oiling engine direct connected to a 75 kilowatt Onondaga generator; the celebrated Diesel motor; a 32 brake horse power horizontal "Hornsby-Akroyd" patent safety oil engine; a 70 h. p. Nash gas engine directly connected to a generator, and a 9 x 12 Woodbury automatic high speed engine of an improved type. This engine, exhibited by Burhorn & Granger, is direct connected to an Eddy 25 kilowatt generator made by the Stearns Manufacturing Co., Erie, Pa. These exhibits and many others which are found in the "Generating Section" of the exhibition will be described later.

The main switchboard of the exhibition was manufactured and installed by F. A. La Roche & Co. It consists of three panels, two being generator panels, one for the exhibition machines and one for the Edison service. The remaining one is the distributing panel. Mounted on the switchboard are the usual measuring instruments and switches.

From the above brief sketch it will be seen that the generating portion of the exhibition is one worthy of this magnificent enterprise and deserving of the most careful inspection of every visiting steam, mechanical and electrical engineer and power user.

Press Reception.

On Friday afternoon, May 6, Mr. Charles Chamberlain, the press agent of the Exhibition, and Mr. Marcus Nathan, the general manager, gave a reception to the members of the press and pointed out to them the main features of the exhibition. A miniature Spanish vessel was blown up by means of Clarke's wireless telegraph device, much to the amusement and gratification of those present. Moore's celebrated chapel was visited by a large number of the representatives.

The Underground Trolley Exhibit.

ONE of the most attractive and instructive exhibits at the Garden is that showing in detail a full size model of car and roadbed for the underground trolley construction of the Metropolitan Street Railway Company of New York with modifications by the Walker Company. The model consists of two rail lengths of track with the standard type girded rail 9 inches high and weighing 90 pounds per yard. Full sized yokes with manholes, frames and covers, with conductors mounted in place show up the method of insulation. A brick paving is placed on a portion of the roadbed, and the underground feeder conduits are placed at the side of the tracks. The conduits consist of 6 ducts imbedded in concrete. The tubes are three inches in diameter and were made by the H. B. Camp Co., of Aultman, O. J. G. White Co. were the contractors for the construction of the conduit.

A full size car of the Broadway type is operated forwards and backwards over the section. The car was manufactured by John Stephenson Co., Ltd., of New York. The body is 22 feet in length, and is equipped with various modern appliances consisting of revolving signs which are operated by means of a small hand wheel beneath the hood and under the inside deck of the car. The car is also equipped at each end with one of the Providence fenders of the model B type, of which over 700 are employed on the Metropolitan System of New York. The car is mounted on a Peckham truck of the Metropolitan special type, having gravity brake mechanism, and special yokes and double outer springs with counter springs beneath to prevent teetering. The wheels of this car were manufactured by the New York Car Wheel Works of Buffalo. The car is pro-

vided with electric headlights and with the Pitt patent gates, manufactured by the Pitt Iron Works Co.

The conduit being left open at the ends, the operation of the trolley or plow by means of which the current is transmitted to the motor is plainly shown. The supporting shank that carries the contact pieces is about six inches wide and one-half an inch thick, and is composed of two steel plates which enclose the conductor. The contact pieces are each about six inches long and are supported on each side of the main bar by horizontal springs. A pair of horizontal rollers is placed near each end of the bar which facilitates the passage of the plow around curves. The feed wires supplying current to the car are furnished and installed in the vitrified conduits by the J. A. Roeblings' Sons Company.

The New York Telephone Co.'s Exhibition Exchange and Display.

IMMEDIATELY upon entering the Garden the visitor catches sight of the splendid exhibit of the New York Telephone Company, which is located near the Madison avenue entrance and is intended to illustrate a private branch exchange system and a model pay station. In the company's space is placed a standard switchboard to which are connected telephones installed in the working departments of the exhibition and in the booths of the exhibitors throughout the exhibition hall. The switchboard also has a system of "trunk lines" connecting with the general telephone system. The various exhibitors are enabled to communicate with each other or with any station in the New York system. The Private Branch Exchange System, shown here, is adapted to large establishments of all sorts. A private switchboard serves as a connecting point for the trunk lines which run to the nearest exchange of the general system, and the lines which branch out from the switchboard to the various offices or departments of the subscriber's premises. This subdivision of the telephone service gives the very acme of efficiency in the conduct of the telephone traffic of a busy establishment. There is no confusion, no delay, no lost calls, and a large volume of traffic can be disposed of without friction. The Branch Exchange System is in use by about 200 large business houses of all classes. In no case has it failed to give complete satisfaction, and to produce an improvement in the service, conducted before with insufficient facilities at the subscriber's end.

The company also have on exhibition four "silence" booths similar to those supplied for the equipment of public or private telephone stations in New York; they are equipped with the different styles of telephone sets used by the New York Telephone Company. Another leading feature of the exhibition is the Theatrophone installed by the company. This consists of a novel single plug switchboard which has connected to it five prominent theatres enabling sixty persons to listen to the plays at any one time. Numerous telephone boys are in attendance and all questions about the working of the exchange are cheerfully answered by Mr. Herbert Laws Webb, to whom is due most of the credit for this superb installation, and Messrs. Wm. E. Huntington and S. D. Brewster, who are indefatigable in their intelligent efforts to serve exhibitors and inform the public.

THE NEW YORK TELEPHONE CO.'S EXHIBIT, WITH THEATROPHONE IN GALLERY, MADISON SQUARE GARDEN.

H. B. Camp Co.

This firm exhibits a very fine assortment of their vitrified clay conduits. The material is a peculiar clay mined in the neighborhood of the works, or it is a combination of different kinds of clay so that several varieties of conduit are manufactured, some being harder and designed to sustain a greater weight than others. The conduit is now manufactured in short sections, the standard being a three-inch inside diameter, with a shell about $\frac{3}{8}$ of an inch in thickness with the corners rounded off. The company also exhibit an old type of multiple duct conduit which they formerly manufactured, but they do not recommend its use, as it is not so convenient for repairs.

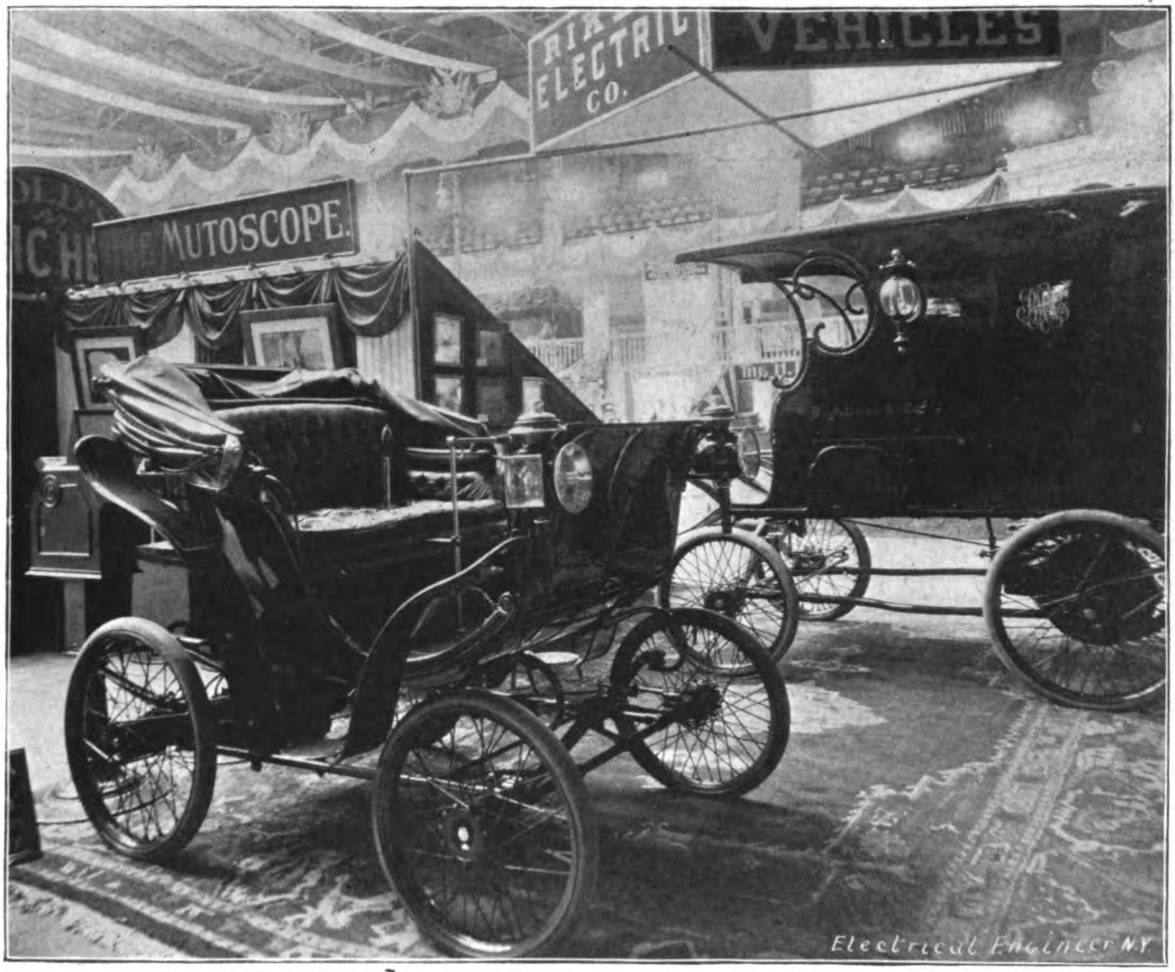
The standard construction is now a single duct conduit laid in concrete with sufficient concrete to separate the ducts and make the joints waterproof. Not only does the exhibit include the street ducts, but also elbows, tees and curved pieces. Among the special pieces are split ducts for repair work. These are manufactured solid, but there is a channel cut on each side so that when it is desired to split a piece for repair work it is easily done by rapping along the side of the duct with a hammer; there are also split tees and and other peculiar shapes. The conduit most recommended is one of dark color and is

made of a special mixed clay made from shale and clay. Besides the conduit proper samples of insulators for supporting the feeder cables on elevated roads are also shown. The company also manufacture fireproof materials for partitions and floors of office and other buildings and almost all products of this kind. The company are particularly fortunate in being located where the different qualities of clay are readily mined and there is also a six-foot vein of coal very near the works. Mr. Daniels is in charge of this excellent exhibit.

Riker Electric Motor Company, of Brooklyn, N. Y.

This company have on exhibition two types of their electric motor vehicles, the one a dry goods delivery wagon, which has been manufactured on an order for B. Altman & Co., of New York, and the body of which was built by Frederick R. Woods & Sons. The cab or body is richly ornamented, having the general appearance of the handsome delivery wagons employed by this company. These are four-wheeled vehicles, the rear wheels being 36 inches in diameter and the front wheels 32 inches, with pneumatic tires. A two horse power motor is employed which is geared to the rear axle, the motor and running gear and band brake being enclosed in a case. The weight of the body is equally supported on the four wheels and the steering is done by means of the front wheels, which are pivoted at the ends of the axle and are carried in either direction by means of levers actuated by a vertical spindle, having a handle which is operated by the driver. The controller is operated by the left hand and the reversing mechanism is operated by foot as is also the brake lever. In the steering handle is a button by means of which an electric bell placed under the foot board is sounded. On the foot board in front of the driver is placed a volt and ampere meter so that the condition of the battery is indicated for the guidance of the driver. The battery in the delivery wagon is placed under the driver's seat and part way back in the body, and may be removed or inserted through side panels which are easily removed. If the roads are reasonably level and in good condition one charge will propel the vehicle 25 or 30 miles. The total weight is 2,900 pounds, of which 1,000 pounds is assigned to the battery.

Besides the delivery wagon, a victoria is exhibited, which has already run over 3,000 miles. The batteries are charged from a 110-volt direct current circuit and are provided with an automatic cut-out so that the charging current is automatically cut off, when the batteries are fully charged. Besides delivery wagons the company manufacture traps, victorias, surreys and two or one passenger buggies.



THE RIKER ELECTRIC VICTORIA AND DELIVERY WAGON, AT MADISON SQUARE GARDEN.

The Peckham Truck Company.

Besides the truck exhibit with the model of the Metropolitan-Walker underground system and with the Walker Company's exhibit, the Peckham Truck Co. exhibit at their booth one pair of their new double trucks for long cars, known as No. 14 B. These trucks are so designed that motors are mounted outside the axles, allowing of a very short wheel base, that in the truck exhibited being four feet. Where one motor only is employed, its position outside the axle tends to so tilt the rear wheels that 65 per cent. of the weight is available for traction. The brake lever is so arranged that by the aid of a spiral spring the pressure on the wheels is in proportion to the weight that each one carries.

The extremely short wheel base limits the sway of the truck on the curves and permits of the body being mounted lower than it is possible to do with the ordinary trucks in which the wheels are all of the same size. The bolster is also constructed in a peculiar manner, giving great freedom of action of the truck on curves, without any tendency to derailment.

The truck on exhibition is one of twenty pairs that have been manufactured to fill a South American order, and is designed for a single G. E. 1,000 motor. This company also manufacture a maximum traction truck, as well as a series of trucks designed to suit any and all conditions of street railway traffic.

The Pump Exhibit of Henry R. Worthington.

THE well known firm, Henry R. Worthington, who have lately gone very extensively into the manufacturing of electrically driven pumps, have taken 1,000 square feet in the centre of the main hall, with an idea of showing at least one of each type of electrical pump which they build. Among others they show a horizontal duplex, having 11" diameter double acting pistons by 10½" stroke, driven by a 50 h. p. General Electric Company motor. The pump and motor are connected by means of a worm gearing which runs submerged in oil. This pump is intended for hydro-electric elevator service, and is a duplicate of one which has been in service for about two years. It is practically noiseless in operation, and is said to be a most satisfactory type of machine for elevator work. A 6x6 vertical triplex pump, driven by a 20 h. p. motor. This pump has three single acting outside packed plungers, and is intended for handling large quantities of water against comparatively light heads. The design is new, and the motor, which is carried on an extension bed-plate, is connected to the main pump shaft by a single reduction of spur gearing, the ratio being about six to one. A 3x4 horizontal triplex connected by a single reduction of gears to a General Electric Company motor, is carried on the same bed-plate as the pump. This is very compact machine, suitable for boiler feed or mine service. The plungers are outside packed and the valves are in separate pots.

They also have a 5x7x3 vertical triplex of the company's "steeple" pattern, connected by one reduction of gears to a General Electric motor. These pumps are designed for a water pressure of 150 lbs., and are fitted with differential plungers; that is, so far as the delivery is concerned each plunger is double acting, giving six displacements for each revolution of the main shaft, which ensures an even and regular flow of water through the delivery pipes.

They also show a number of their small electric pumps, suitable for house tank service, in operation, and connected with automatic tank switches which stop and start the pumps automatically, keeping a constant supply of water in the tank. These pumps are noiseless, the connections being made by belt, and not by gears.

Besides these they are exhibiting a small duplex pump, directly connected to a gas engine; an 8 and 12x9x10 compound direct acting air compressor; a 7½x16x10 vertical beam air pump; and one of their "Admiralty" pattern boiler feed pumps. This last pump is of the same design as those used on the U. S. battleships "Iowa," "Kearsarge," and "Kentucky."

They also show the '98 model of their regular pattern steam pump. This is an entirely new design, embodying many new features.

This splendid exhibit, shown in the illustration, is the largest and one of the most complete at the Exhibition and is in charge of Messrs. F. W. Jones, Jr., G. M. Maynard, and E. R. Howell.

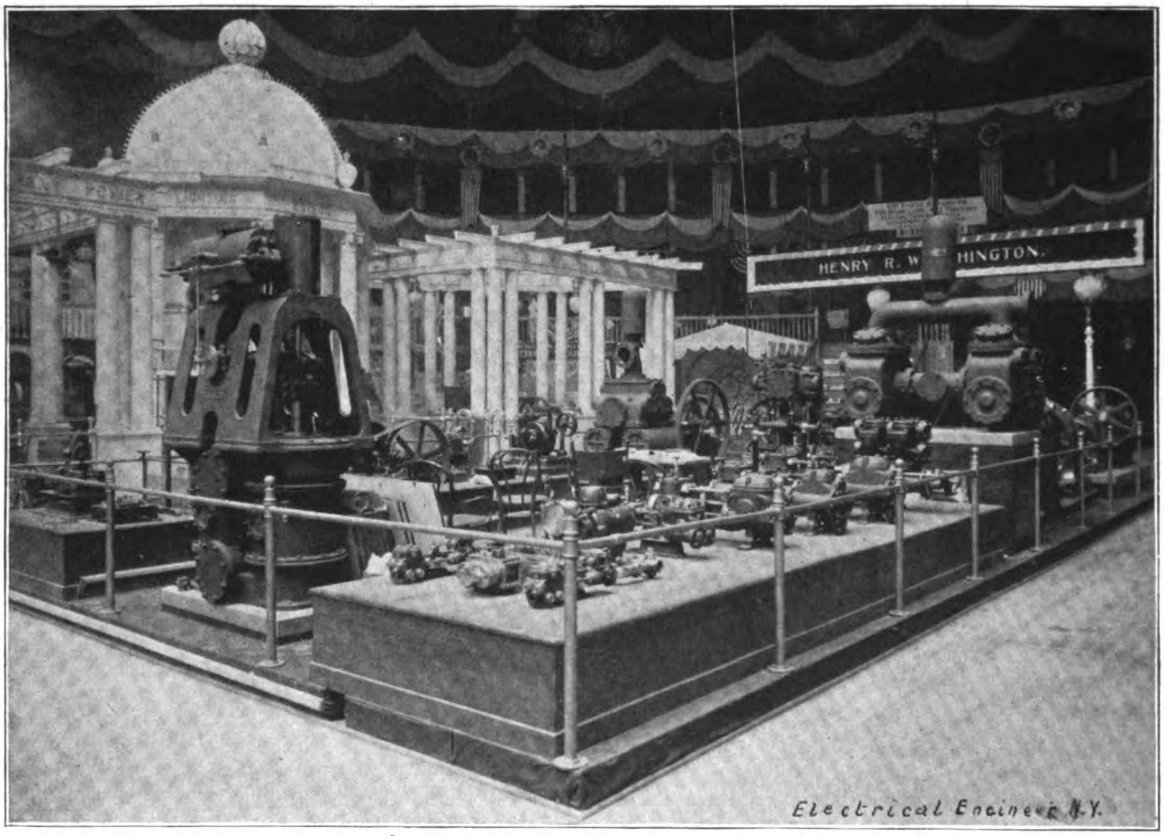


EXHIBIT OF HENRY R. WORTHINGTON AT MADISON SQUARE GARDEN.

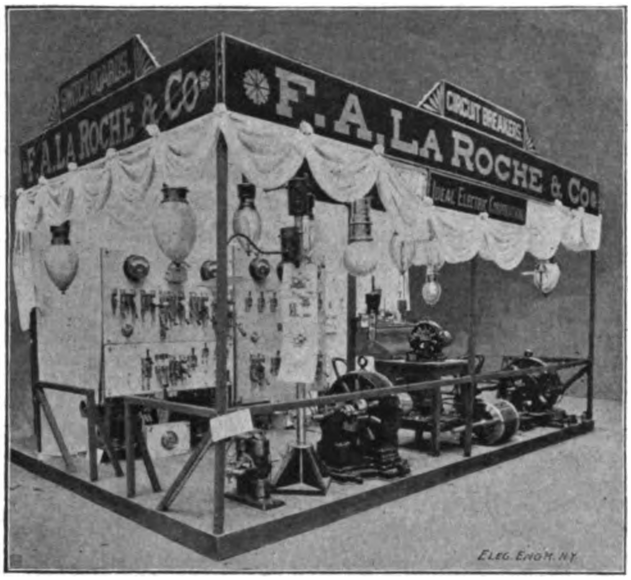
F. A. LaRoche & Co.'s Exhibit.

ONE of the most attractive and complete exhibits at the Exhibition is that of F. A. LaRoche & Co. and the Ideal Electric Corporation consolidated. The firm show one of their modern switchboards, which is built for one of the large dry goods establishments in New York City. This board is of exceptional beauty; on it are mounted the well known "Ideal" circuit breaker and the LaRoche self-locking switches with Weston instruments and all other switchboard features, also a new and novel rheostat dial which is said to be the best thing on the market to-day. The board is made up of Knoxville grey marble, mounted on heavy angle iron frames with brass pedestals, and is one of the most substantial and businesslike boards in the Exhibition. The bus-bar work on the rear of the board is a fair sample of the class of work turned out by this firm who have made quite a reputation in that line in the past three years. They also have a switchboard containing ten "Ideal" circuit breakers, ranging in sizes from 25 to 2,000 amperes; as well as a single and double pole. This test board, as it is called, is mounted on angle iron frames attached to a motor and dynamo which are direct coupled, and the dynamo is wound to give 5,000 amperes, thereby showing the above switchboard in constant and practical operation; and one of the breakers, a 1,000 ampere break, was seen by the writer to break a circuit of 3,000 amperes without excessive heating or sparking. The manager of the firm reports that their factory is running 18 hours daily to supply the demand for their improved circuit breaker. The appearance and style and operation of the circuit breaker substantiate this statement.

The booth is handsomely decorated and is lighted by the well

known La Roche alternating and direct current arc lamps. It is well to mention a few advantages of this arc lamp: It is one of the simplest and most substantial arc lamp yet offered to the public, and the simplicity of the mechanism, the steadiness of the light and its economy should certainly commend it to all users of arc lamps. The central station manager would do well to inspect this lamp, as it is a lamp that will stand a great deal of hard usage and is not liable to get out of order owing to its simple construction. They are of the enclosed type for alternating current and are made up in a number of various neat designs. This firm also manufacture a focusing alternating current arc lamp which is a novelty in itself. They also manufacture the well known LaRoche alternating current dynamos, of which they show a complete line ranging from 1½ to 150 kilowatts. They also display quick break switches, as well as ordinary knife blade switches, which are made up of pure hard drawn copper, guaranteed to be free from all impurities. No castings are used in their construction. The self-locking switch



THE F. A. LA ROCHE & CO. EXHIBIT.

made by the firm is claimed to be the most practical switch yet offered to the public. The idea of the switch is that the act of closing it automatically compresses the hinge post and clamps the blade tightly between the clips of the hinge post, and there is an adjusting screw, so that any degree of compression can be obtained. The patent is owned and exclusively controlled by F. A. LaRoche & Co.

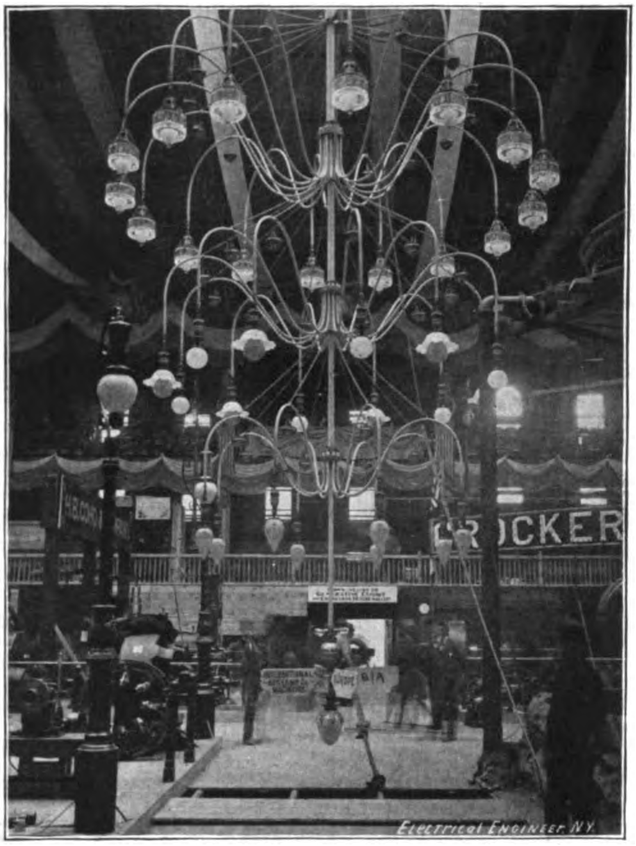
The firm manufacture numerous sizes of direct current machines as well as motor dynamos and rotary transformers.

It might be well to mention that the main panel switchboard furnishing the power and light for the entire Exhibition was manufactured and installed by F. A. LaRoche & Co., and the board was delivered in four days from receipt of order. The exhibit is in charge of Messrs. J. A. Loutey, A. E. Wells and F. A. LaRoche.

The Arcolier and Other Exhibits of the International Arc Lamp Co.

Of all the numerous novel appliances and apparatus shown at the Exposition there is perhaps but one which is so extremely new that a name had to be coined for it, which will on account of the admirable features possessed by its bearer, we are sure, soon become a "household" word in electrical engineering. "Arcolier" is the word which has been so happily chosen to designate the pendant of arc lamps, arranged as tastefully and æsthetically as are the incandescent lamps on the less brilliant and impressive electrolier. The honor of having designed and installed the first "arcolier," and one of gigantic dimensions, is due to Mr. Geo. R. MacIntire, who has designed numerous artistic arc lamp fixtures and globes. The "arcolier" consists of 37 enclosed arc lamps, giving a total of 40,000 c. p., and it weighs 1,500 pounds. The lamps consume from 4½ to 5 amperes at a pressure of 80 volts across the arc. To a motor in the base of the arcolier are attached four wooden blades pointing to the four quarters of the globe, which revolve slowly and add largely to the gorgeousness of the display.

Besides exhibiting the arcolier, the International Arc Lamp Company have the following lamps in operation at various portions of the Exhibition: Eight special lamps on cornice of Edison Electric Illuminating Company's temple and two ornamental post lamps at portals of same; two ornamental post lamps facing Madison avenue entrance, in the Henry R. Worthington exhibit; one ornamental prismatic pendant, Madison avenue entrance balcony; two ornamental post lamps, N. Y. Electrical Society booth; one silverine lamp pendant, The Electrical Engineer booth; one pendant, National Carbon Company's booth; two brass polished newel post lamps at speaker's rostrum; two service lamps, Nash Engine Company, basement; one polished brass pedestal at "Electrical World" booth; and one pendant, "Western Electrician" booth. The steadiness of the light and the beautiful designs of standards and pendants have won for Mr. McIntire and his company well deserved praise.



THE McINTIRE ARCOLIER AT THE EXHIBITION.

Keuffel & Esser Co.

This company make a very fine display of drawing instruments of every description, slide rules and recording machines, in fact, almost every tool that is usually sold for use by mechanical and designing engineers. There are also planimeters and a large assortment of Excelsior steel tape line together with field instruments and leveling poles. The exhibit also includes a blue print frame mounted on rollers and casters of peculiar construction and various stationery material used by engineers. There are also section liners, slide rules together with sextants, compasses, telescopes, etc. In another case are aneroid barometers, machinists levels, including a new level which has a double main bulb and a smaller right angle bulb; in addition there are mining compasses, pantographs, etc.

The number and variety of tools and appliances which are provided for operators in this branch of technical work, are strikingly illustrated by this exhibit. A novice would have no idea that so many useful instruments could be designed and shown in so attractive a manner as is shown by this company.

The National Carbon Co.'s Exhibit.

A very artistically arranged and interesting exhibit is that of the National Carbon Company, of Cleveland, Ohio. They show a great variety of their well-known products, principal among which may be mentioned the National Nos. 2, 3, 4 and 5 carbon porous cup cells, the Klondike and Le Clanche porous cells, special gas engine cells, varieties of cylinder

THE NATIONAL CARBON CO. EXHIBIT.

and Fuller type cells, gravity cells, back-plates, diaphragms, granular and globular carbon, lightning arrester plates, carbon boxes, plates, tubes and strips, filament blocks, special battery cups, carbon brushes, arc light carbons and smelting electrodes. The exhibit, which is shown in the illustration, is in charge of Messrs. Richard O'Connor and M. H. Moffett.

Gold Street Car Heating Co.

The electric heaters exhibited by the Gold Street Car Heating Company cover every style of electric heating device used for warming cars, houses, boats or buildings. All of these heaters are fitted with the Gold improved resistance coil and support, shown in the accompanying engraving.

As can be readily seen from the illustration this method of

THE GOLD ELECTRIC HEATER EXHIBIT.

supporting the resistance coil of an electric heater is quite novel. It is compact, simple, efficient and durable. A large amount of Gold's resistance wire is contained on this support and the very freest circulation of the air takes place through this coil at all times so that the highest efficiency is obtained, the distribution of the heat being always maintained in a uniform manner.

A large number of heaters are exhibited and they are all very handsomely designed; in fact it is claimed to be the largest display of electric heaters that has ever been put on exhibition and containing a great many different forms and styles adapted

METHOD OF SUPPORTING RESISTANCE COILS FOR GOLD HEATERS.

to the numerous requirements which the Gold Company have met.

The exhibit is looked after by Mr. Fred. Weston and Mr. H. E. Beach, the Eastern representative of the company. Mr. John E. Ward, the manager of the company, and Mr. Edward E. Gold, the president, are often in attendance during the evening explaining the merits of their improved devices to their numerous friends who attend.

The Hospital Service Exhibit of the American Electrical and Maintenance Co.

ABSOLUTELY new ideas are scarce in the electrical profession, but this exhibit is not only new, but unique. There are shown the appliances and materials used in the repairs of electrical machinery, which have become a very important feature in the kindred trades using electric current.

The American Electrical and Maintenance Company have

AMBULANCE OF THE AMERICAN ELECTRICAL AND MAINTENANCE CO.

systematized their branch of the business and have arranged a department for the special care of motors, dynamos and installations, in which they employ an experienced staff of inspectors who periodically inspect apparatus and take all risk of wear and tear of same for a small sum per annum, making good all worn or damaged parts, such as brushes, armatures, fields, instruments, etc. Moreover they keep specially for this purpose an ambulance which can be called out on special emergency work by a telephone message to 881 Franklin or 1398 Franklin. The shops of the company are situated in the most convenient situation at 451 and 453 Greenwich street, corner of Desbrosses street, New York, and are never closed, and at any time day or night it is possible to obtain a gang of men who are efficient to straighten out the most extensive of breakdowns.

No one using electrical power should miss a visit to their

exhibit and shops, as the latter is a permanent exhibition in itself. All classes of machinery are there repaired, and the company's plant is known among the trade as the "Electrical Hospital," which it is in every sense of the word.

The American Electrical and Maintenance Company is a continuation of the well known firm of A. K. Warren & Company, Mr. Aldred K. Warren being the president of the new company, who takes the active superintendence of all their technical work. The general management is in the hands of Mr. George Stanmore, who has been connected with the present and past firms for over five years; and their well known trade-mark, the White Cross, is a guarantee of good and quick service.

The Moore Exhibit at Madison Square Garden.

UNQUESTIONABLY the most popular exhibit at the Garden is that of Mr. D. McFarlan Moore. The crowds which this inventor's exhibit attracted at the last Exhibition in 1896, extensive as they were, are far outnumbered by the numbers which throng the Moore vacuum tube lighted chapel every day and evening. And no better indication of the practical advances made by Mr. Moore could be desired than the nature of the two exhibits referred to. The earlier exhibit, it will be recalled, consisted of a small enclosed booth, barely 10 feet square, with a dozen tubes arranged about the space, into which 20 persons could barely enter, and who had to make way quickly for those waiting in line behind them. The light tubes at that time were operated by Mr. Moore's vacuum vibrators, one to each tube.

The present exhibit of Mr. Moore may be said to be a radical departure and improvement in every way, down to the smallest detail. To begin with, instead of being cooped up in a mere cubby-hole, Mr. Moore has availed himself of a space upon which he has erected a chapel complete in every detail and in which he shows to perfection the manner in which vacuum tube illumination can be carried out in practice.

Ascending from the Lecture Hall the visitor is introduced into a passageway leading to the chapel along which Mr. Moore has sought to give the pilgrim a five minutes practical course in the applications of electricity, which is alluded to more fully below. Emerging from a bend in the passage the front of the chapel suddenly looms up a perfect reproduction of a stone village church, steeple, clock and all, Fig. 2. The front doors are open, above the arches of which shine forth in vacuum tube letters the words, "Moore Vacuum Tube Chapel." Within is seen the vaulted roof ribbed with veritable arches of light consisting of long curved tubes of glass about 2 inches in diameter and glowing their entire length with a pure white light. The harmony of the surroundings is everywhere observed. The ear is gratified with melodious strains from the magnificent pipe organ, which fills the far end of the chapel behind the altar fully equipped, even to the lectern. Specially designed quartered oak pews with luxurious cushions invite the visitor to rest and meditation.

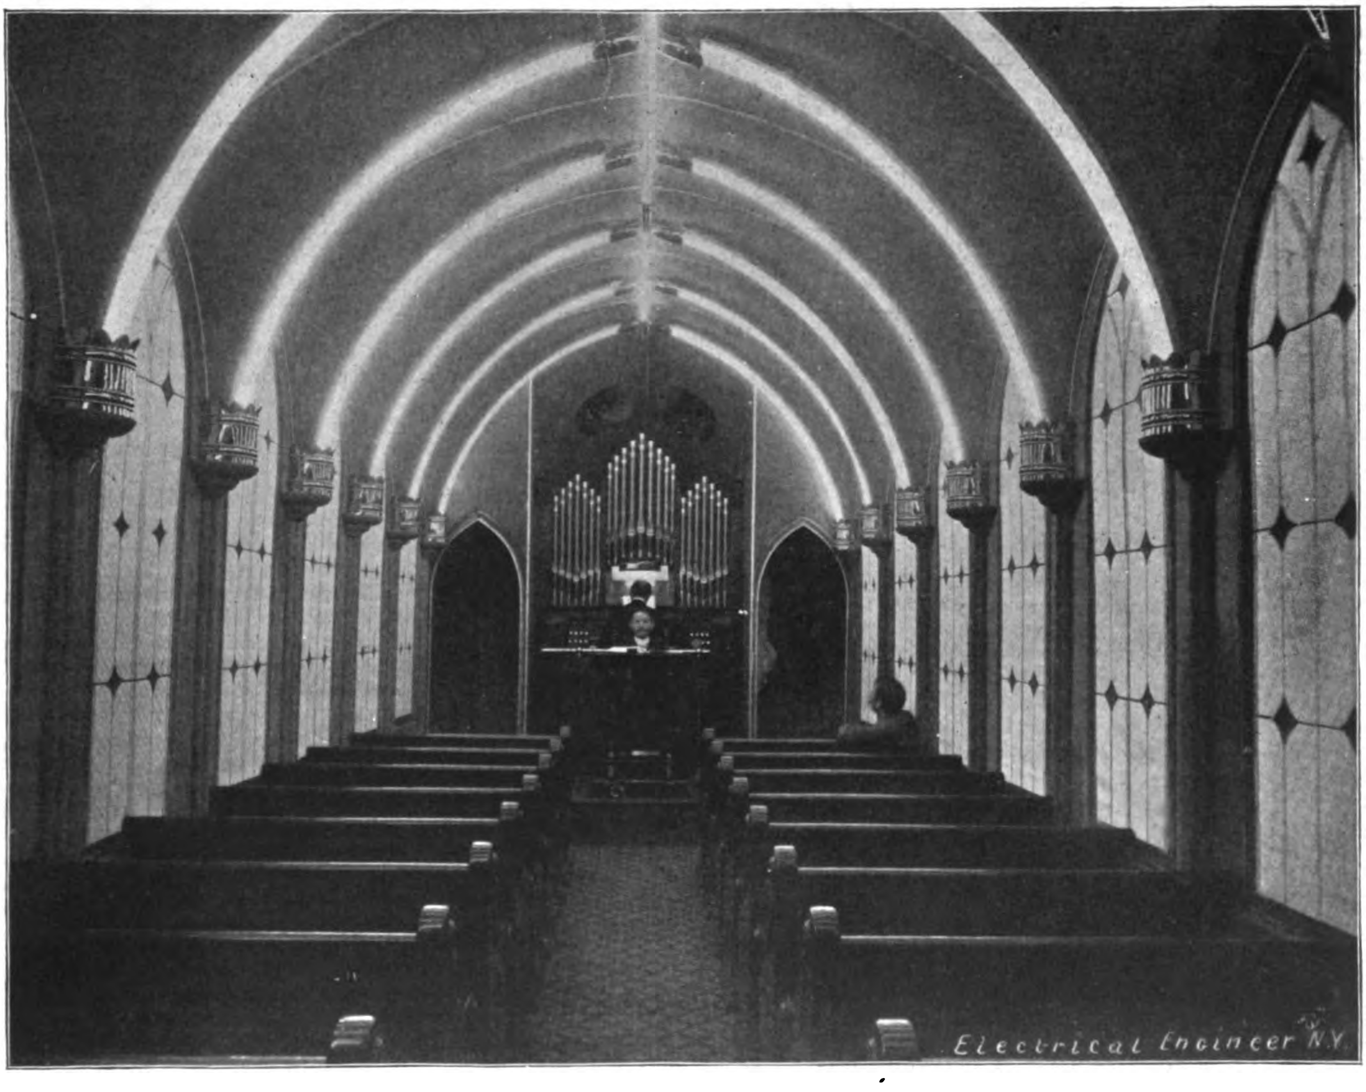


FIG. 1.—THE MOORE CHAPEL LIGHTED BY VACUUM TUBES, AT MADISON SQUARE GARDEN.
(Photographed by the light of the tubes solely.)

The predominating color of the frescoing is yellow and the imitation stained glass windows look perfectly natural.

The tube arches spring from pilasters, each capped with a highly polished, specially designed brass fixture, seen in Fig. 1. They take the form of a crown while at the apex of the chapel ceiling, where the tube arches meet, they are joined by a highly

decorated brass cylinder bent at its centre. The fixtures supporting the longitudinal tubes at the apex of the ceiling are also seen in Fig. 1.

These are the first vacuum tube lighting fixtures ever designed, and are a striking example of the manner in which Mr. Moore has worked out the one thousand and one details of his lighting system. In this connection it should be mentioned that the chapel is wired completely with iron armored conduit, again inaugurating that, which will soon become standard.

As one passes out of the exits on the sides of the organ, it is noticed that the chapel is ventilated by two 24-inch exhaust blowers over the organ pipes. A last look is attracted by the colored vacuum tube letter sign over the rear door "Let There Be Light." This is the same sign used by Governor Morton in opening the exhibition of 1896.

The church is wired with the Moore three-wire system of vacuum tube lighting; that is, all of the tubes—16 arch and 3 ridge tubes—are connected in parallel between three wires. The common or positive wire extends along the ridge, while each of the two negative wires extends horizontally along the side of the chapel back of the side fixtures, which rest on top of the pilaster caps. The three wires enter the top of a polished oak cabinet, 2 feet by 2 feet by 4 feet, which contains all of the lighting apparatus and is situated on one side of the entrance passageway as seen by Fig. 3. There also enters this cabinet at the top, the three wires connecting with the street service of the Edison Electric Illuminating Co., again fulfilling a point first called attention to by Mr. Moore, namely, that vacuum tube lighting must make its start by being adaptable to the present commercial circuits.

It will be remembered that one of the salient points in Mr. Moore's system is the breaking of the current in a vacuum. This he accomplishes by means of a beautifully constructed rotator, which is shown complete in Fig. 3. Surrounding the

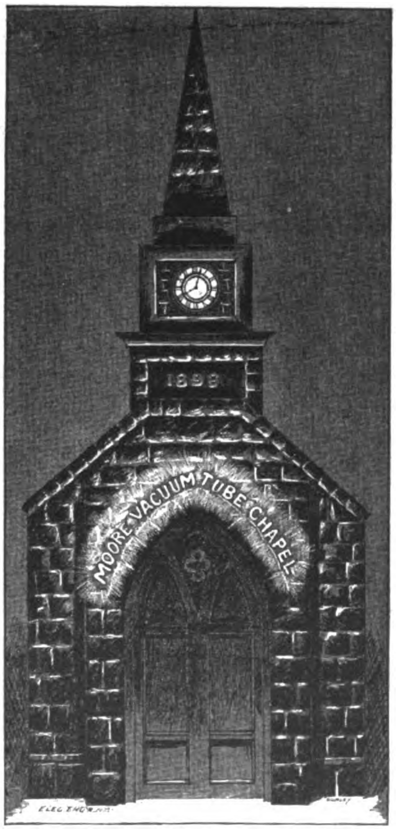

FIG. 2.—THE MOORE CHAPEL, ELEVATION.

rotator proper, which is of glass, 3 inches in diameter and a foot long, is a Gramme ring with its highly polished brass mountings, the whole constituting a beautiful piece of practical apparatus.

The apparatus just described is all that is necessary where multiphase currents are available; but in the present instance the lower comparatment of the cabinet contains a small rotary transformer.

According to Mr. Moore, the system at its present stage of development has an efficiency about equal to incandescence; but the inventor looks for still better results with improvement in the tubes—a problem he is about to take up.

Besides the rotary vacuum break Mr. Moore has gotten into

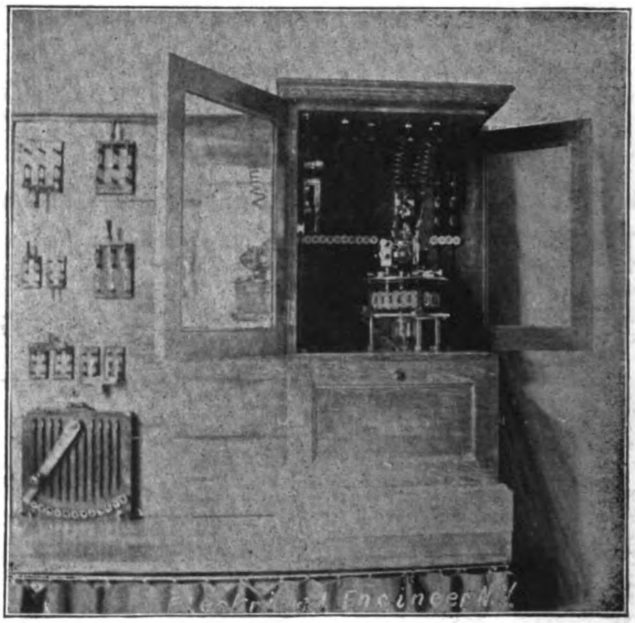

FIG. 3.—THE MOORE ROTATOR.

commercial shape a vibratory vacuum break. This apparatus will be extensively used for advertising purposes. It can be used either on direct current circuits or alternate current circuits.

There are also many other applications for this system of lighting. For example, the color of the light, even to the most delicate shades, can be changed simply by changing the degree of vacuum of the tubes, making it the ideal light for special decorative lighting. Another large field is in connection with photography—for photographers have long been longing for a light which they could regulate to a nicety and thereby obtain uniform results. At the Electrical Exhibition in 1896 Mr. Moore took instantaneous portraits by his light.

It has long been a matter of expectation as to when and by whom vacuum tube lighting apparatus would first be placed on the market, and the fact that Mr. Moore is now taking orders is extremely interesting since it is a beginning of a new departure in electrical work, which is destined, without doubt, to wide application.

In connection with the chapel exhibit, Mr. Moore has carried out a pet idea of his, which in itself is a great attraction and diversion, and in which he gives the public a chance to become personally acquainted with electricity, as it were. On a table extending along the side of the passage leading to the chapel are arranged the special attractions, every one of which is operated by the visitor closing the various switches in succession.

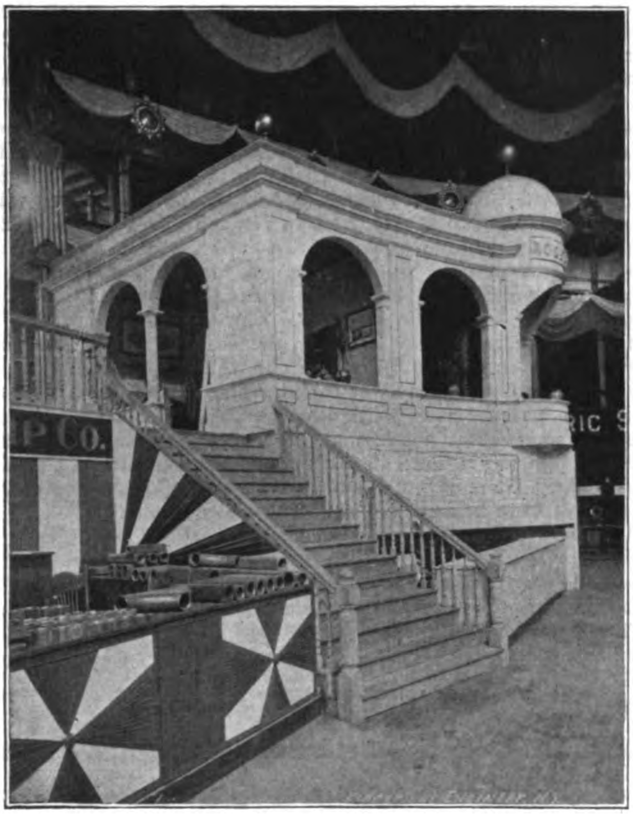
The first is a simple bell outfit consisting of battery, bell, and push button arranged so simply that everybody can understand it. Then follows an electric motor which starts so suddenly as to frighten the innocent visitor into wondering what he or she has done. Next comes a front door name-plate in vacuum tube letters; then electric fishing, a realistic bit of fun; poaching eggs by electricity; tube lighting by induction; and, finally, as the visitor is handed a pretty souvenir in the shape of a miniature vacuum tube, he receives a slight shock.

Electric Embroidery Machine.

Mr. F. Heilrath is operating the electric embroidering machine at space No. 175, main floor. The handkerchiefs embroidered with the name of the purchaser and also Old Glory are very appropriate souvenirs of the show and are in great demand.

John A. Roebling's Sons Co.'s Display.

ONE of the most tastefully arranged and most comfortably fitted out exhibits is that of the John A. Roebling's Sons Co., of Trenton, N. J. It consists of a very handsomely designed booth, arranged near the Fourth avenue entrance to the Garden, with a finely appointed reception room in the rear. The exhibit room is filled with a general line of the company's various wires and cables from the electrical department. Particular attention has been given to lead-covered cables for underground service; various types of lead encased cables with rubber, jute, and paper as the insulating material. A notable part of the exhibit is a



THE J. A. ROEBLING'S SONS EXHIBIT.

section of a three-conductor submarine armored cable, which is in all respects like one just finished at their factory—some thirty miles in length. In addition to showing these cables in original packages as sent out from the factory, they show various wires in short sections, arranged as neatly as this material can be in a place of this character. The exhibit which does credit to this very enterprising company, and is shown in the illustration, is in charge of Mr. W. S. Doyle, assisted by Messrs. M. R. Cockey, A. M. Whitaker and G. W. Swan.

Berlin Iron Bridge Company.

This company occupies a large booth seventeen feet square built of channel iron, having a gable roof. The posts and trusses are riveted and braced after the manner of the prevailing bridge and building construction followed by this company. The roof is provided with the anti-condensation roof lining which is held in place by a wire netting. Above the netting is placed a sheet of 14 pound asbestos and upon this a sheet of 6 pound asbestos and then two sheets of tar paper which is corrugated next to the iron roof. This renders it not only waterproof, but fireproof. With a bare iron roof the drip from condensation is not only annoying, but injurious to machinery and goods that may be stored on the floor; this the lining is designed to remedy.

The booth is also equipped with a specimen of the crimped iron cornice manufactured by the firm, and is decorated with a large number of framed photographs of bridges, power houses, engine houses, car sheds and other buildings which have been constructed by the company. The company is represented at the Garden by Mr. Seymour N. Robinson, the New York manager of the concern.

Niles Tool Works Co.

A large space is occupied by a fine display of the leading tools manufactured and sold by this company. The exhibit has been installed by the Eastern branch of the company, located at 136 Liberty street, New York, but the factories, which are among the largest in the world devoted to this industry, are located at Hamilton, Ohio. Special attention is given by the firm to fitting out with suitable tools, street railway and electric light repair shops, and a full line of tools has been designed and manufactured which are operated by independent electric motors, a very desirable and economic method of employing power where current is to be had. The exhibit includes planers, engine lathes, foot lathes, universal milling machines, shapers, turret headed drill presses, together with a great variety of all wrought steel, "American" patent pulleys, for which the company are selling agents.

The large planer on exhibition has a capacity for work 32 x 32 inches with a bed travel of ten feet, and is provided with two heads on the cross bar and, when required, with two side heads. The bed plates are broad and deep with double webbed housings. Power is transmitted by tangent gears running in oil, and perfectly noiseless, while the driving shaft runs in bearings composed of copper and tin, giving long life and a minimum of friction. The method of drive employed affords a steady and uniform motion of the table which reverses without shock or jar at a speed of 4 to 1, and always accurately. The patent belt shifter here employed is a peculiar feature of these planers and is so designed that only one belt is shifted at a time, which prevents any squeaking or squealing of belts, as is the case where two belts running in opposite directions are tight on the pulley at the same time. The feeds are automatic in all directions. Machines of this description are manufactured by the company with a capacity for stock up to 120 x 120 inches and with any length of bed plate.

Some of the special features of the five engine lathes on exhibition, besides being made of high grade material and superior workmanship and finish, are the deep beds, five-step cones, and graduated handles to indicate lengths of travel. The feed cones are arranged on a bracket which may be used for a belt tightener when necessary. For thread cutting it is necessary to remove only one gear in order to cut threads of any pitch. The apron is so arranged that it is impossible to throw in the rod and screw feeds at the same time. The machines on exhibition have a range of swing from 14 to 18 inches.

A model foot lathe is also shown, which is specially designed for the use of amateurs, experts, and inventors in constructing models to illustrate their various devices.

The special feature of the universal milling machines is that the table is placed on the right instead of the left side, making it easy and handy to operate.

Among the drills shown is a vertical turret headed borer with which great advantage is obtained in the quality and quantity of work. The turret head having four holes, this number of cutter-bars can be adjusted at one time, which secures absolute accuracy in work; for instance, a drill cutter-bar, counter-bore and reamer, or any other combination may be operated without resetting the work. The machines have a range of 30 inches in diameter and are designed for boring 14 inches.

A special feature of the exhibit is a great variety of the all wrought-steel pulleys for all kinds of belt transmission. These pulleys, as the name indicates, have the rim and spokes stamped from sheets of mild steel. The edges are rolled under and a web on the under side of the rim gives strength and provides a stiffener of metal and serves for the attachment of the double spoke-arms which are bolted to the peculiar shaped hub.

The special claims made for the pulleys of this type are lightness and strength, as they weigh only about one-third as much as ordinary cast-iron pulleys and about the same as wooden pulleys, while they have a high tension resistance and may be run at high speed. The smooth round finish of the edges prevents the cutting of belts and injury to the hands of the operators when it becomes necessary to shift the belts.

The hub, by means of steel bushings, is made interchangeable to fit shafts of different diameters, and can be readily removed from one shaft and adjusted to another.

Besides the tools manufactured by the Niles Tool Company

proper, the Eastern Branch handles steel hammers, electric cranes, and other large tools made by the Morgan Engineering Company, and large punches and shears manufactured by Long & Allstatter and which are designed to be driven by belts, from shafting, or by independent electric motors.

SOCIETY & CLUB NOTES

New York Electrical Society.

The 187th meeting of the society will be held in the Concert Hall, Madison Square Garden, on Thursday, 12th inst., at 8:20 p. m. There will be a short session for the transaction of current buisness, and at 8:30 Dr. Schuyler S. Wheeler will lecture on "Electrically Driven Machinery."

The lecture will be illustrated by experiments and lantern slides. The evolution of electrical machinery, as influenced by the gradual change from belt driving to electric driving will be traced, and the modifications of design making for greater simplicity thus rendered possible will be demonstrated.

Admission to the Garden can be had by the special ticket issued to the members of the society which can be obtained—price 25 cents—from the society's booth in the Exhibition any night from 8 to 9, or on application to the secretary. Ladies are admitted to the lecture, but each ticket gives admission to the building to only one person.

Meetings of the National Association of Stationary Engineers.

As previously announced, a large number of local chapters of the National Association of Stationary Engineers will hold their meetings in the Concert Hall of Madison Square during the Electrical Exhibition.

The following is a schedule of the chapters and the days on which they will hold their meetings: May 7, No. 6, New York, and Nos. 2 and 11, New Jersey; May 9, No. 33, New York; May 10, No. 29, New York; May 11, Nos. 4, 11, 13, 15 and 16, Connecticut; May 12, No. 2, New York; May 13, No. 27, New York; No. 1, Connecticut; May 14, No. 7, New York; May 16, No. 31, New York; Nos. 10 and 1, New Jersey; May 17, No. 42, New York; May 18, No. 39, New York; May 19, No. 23, New York City; May 20, Phœnix, No. 24, New York; May 21, No. 3, New Jersey; No. 8, New York; May 23, Nos. 32 and 47, New York; May 24, No. 1, New York; May 25, Nos. 55, 41, New York; May 26, No. 44, New York; May 27, No. 25, New York.

A large number of delegates are already in town, and have visited the Exhibition. They have expressed themselves as being much pleased with its practical features. Their names, destination and employment are registered on bulletin boards near the entrance to the exhibition hall and in the operative exhibit in the basement.

THE NORTHWESTERN ELECTRICAL ASSOCIATION.—Messrs. Edison, Thomson and Sprague have accepted the invitation from the cities of Duluth and Superior and the Association to be present at the convention in June as honorary guests.

THE "GALVANOPLASTIC," a well known firm of electrotypers and stereotypers in Berlin, Germany, has recently been fitted out by F. Wesel & Company of New York City, with an up-to-date plant. Every machine run by power has its own separate Lundell electric motor, and the motors were supplied by the Sprague Electric Company of New York. It is said that this is the first and only plant of this description in the world at the present time, operated in this way, and it will no doubt attract a great deal of attention here as well as abroad.

MR. W. MAVER, JR., has removed his offices to the Beard Building, 120 Liberty street, and is a welcome addition to the large electrical and engineering colony there.

NEWS AND NOTES

The First Spaniard Captured.

MR. JOHN W. EBERT, who represents the Western Electric Company in Mexico, scored the first victory over the enemy, April 20, as shown by the following extract taken from a newspaper, "The Two Republics," published in Mexico: "Two gentlemen of this city recently paid a visit to the State of Guerrero on business connected with electric installations, Messrs. Ketchum and Ebert. On their return they stopped at Jojutla and put up at the hotel there. It happened that a Spaniard occupied one of two adjoining rooms and the landlord, wishing to oblige the two Americans, by giving them these rooms, shifted the Spaniard to a down stairs room. Messrs. Ketchum and Ebert went down to supper, and on returning to their rooms, a revolver and belt, the property of Mr. Ebert, were missing. The landlord was at once notified and on inquiry found that the haughty Spaniard had been seen sneaking down stairs, from above, where he had no business. The landlord charged him with the theft, which the Spaniard denied, and on the landlord insisting on searching his trunk and the suspect refusing to permit same, a gendarme was called. The Spaniard again made objection and the jefe politico was called in to take a hand. He very soon settled the matter by locking the Spaniard up and keeping him in jail until he chooses to open his trunk for examination. There is no doubt that he stole the articles or he would not have hesitated to open and show up at first.

So the first Spaniard has been captured by an American and held as prisoner. If every one of our boys does as well as Mr. Ebert the war will soon come to a close." Later advices direct from the seat of war state that the revolver and belt were found in the Spaniard's trunk and that he will spend six months in a Mexican prison.

Mr. C. E. Dolbear's Submarine Telegraph Tests.

The manifest necessity of establishing communication between vessels at sea and the shore in time of war has induced numerous inventors to try methods for accomplishing this end. Of the electrical methods tried, perhaps one of the oldest, but least developed is that of simple conduction, that is, taking advantage of the fact that a current flowing between two points not metallically connected spreads out in waves and covers a wide area, depending upon the conducting material, the strength of the current, and distance between the terminals. To determine the relation between these quantities and the possibility of practically employing this means of communication between our vessels now stationed in Southern waters, near the Florida and Cuban coasts, Mr. C. E. Dolbear, a son of Prof. A. E. Dolbear, of Tufts College, made arrangements with the New York "World" to carry on extensive experiments in the Kill von Kull, a channel of salt water, between the New Jersey and Staten Island shores. Fifteen hundred feet of No. 14 copper wire stretched along a rocky ledge between the railway station of Sailor's Snug Harbor and an old mill. The two ends of this wire were connected to copper plates immersed in the water and a telegraph key and a number of Mesco dry batteries were placed in the circuit. After these preliminary arrangements a party consisting of Messrs. T. A. Edison, Jr., C. E. Dolbear, W. J. Clarke, Charles Cuttriss, Chas. W. Price, Max Loewenthal, O. S. Burr, W. H. Holzer and "World" representatives, Messrs. Young and Miller, embarked on the tug "Leonard Richards" on Thursday, May 5, to conduct the experiments across the Kill von Kull, a distance of a quarter of a mile. A wire whose ends were connected to plates of copper inserted in the water over the bow and stern of the tug was cut in the middle and a telephone receiver placed in circuit. A provisional code was adopted and signals transmitted from the shore were plainly heard by those on the tug. The experiments may be considered highly successful, and may lead to gratifying and beneficial results.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued April 26, 1898.

Batteries, Secondary:—

STORAGE BATTERY. E. A. Barber, Watertown, N. Y., 603,229. Filed September 13, 1897. Comprises a series of independent superimposed oxidizable metal trays, electrolyte therein, asphalt covering for the surfaces of the trays exposed to the electrolyte, to prevent the trays from becoming gradually oxidized and destroyed, the positive and negative plates and electrical connections between each of the plates.

Conductors, Conduits and Insulators:—

ELECTRIC CABLE. N. G. Warth, Indianapolis, Ind., 603,069. Filed Oct. 25, 1897. Comprises one or more separated conductors and an impermeable and hermetically sealed conductor holder which incloses the conductors and contains compressed air or like gas confined for service as a dielectric.

LINING FOR INTERIOR CONDUITS. S. Bergmann, New York, 603,230. Filed Nov. 24, 1896. Consists in treating a tube made from an absorbent vegetable fiber in a bath of fireproof material, then treating it in a bath of drying oil, and finally drying the tube so treated.

Distribution:—

DISTRIBUTION OF ELECTRIC CURRENTS. E. Thomson, Lynn, Mass., 602,968. Filed Dec. 6, 1896. Provides means of adjustment of the primary coil of the induction coil without loss of energy to suit the potential at different points of the main line, or to suit the lamps used on the secondary local lines.

Dynamos and Motors:

ALTERNATING CURRENT INDUCTION MOTOR. C. P. Steinmetz, Schenectady, N. Y., 602,920. Filed Feb. 12, 1897. A method of compensating for the self-induction and magnetizing current of an alternating current motor, which consists in inducing from the secondary of the motor leading currents in a tertiary closed circuit in inductive relation to the secondary member.

ALTERNATING CURRENT INDUCTION MOTOR. C. P. Steinmetz, Schenectady, N. Y., 602,921. Filed Feb. 12, 1897. A method of giving starting torque to an alternating current induction motor upon a single phase circuit, which consists in producing and maintaining leading currents in a closed electric circuit in inductive relation to the primary and secondary circuits of the motor.

ELECTROSTATIC GENERATING MACHINE. A. H. Hoyt, Penacook, N. H., 603,041. Filed Aug. 9, 1897. Combines with the terminals for the working circuit spark gap arms adapted for longitudinal and rotative adjustment within their posts.

DEVICE FOR TURNING OFF COMMUTATORS OF DYNAMOS OR MOTORS. W. H. Jordan, Brooklyn, N. Y., 603,061. Filed Jan. 28, 1897. An adjustable support adapted to be clamped to the base of dynamos and motors, the support comprising a clamping plate adjustable thereon, and a standard on the last named plate, upon which the turning-off apparatus is adapted to be secured.

Electro-Metallurgy:—

PROCESS OF EXTRACTING TIN FROM TIN PLATE WASTE. J. Neumark, New York, 603,200. Filed Sept. 10, 1897. A process of regenerating an alkaline electrolyte charged with salts of tin, which consists in adding phosphoric acid to the electrolyte and, after the reaction which takes place is complete, adding calcium oxid to the electrolyte.

Electro-Therapeutics:—

ELECTRIC MASSAGE APPLIANCE. F. J. S. Lau, Kansas City, Mo., 602,950. Filed July 23, 1897. Details of construction.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. E. Thomson, Swampscott, Mass., 602,922. Filed Nov. 4, 1897. Combines with the feed mechanism, a thermo-electric expansive device, and a series electromagnetic controlling apparatus, responsive to variations in the current passing through the lamp governing the operation of the thermo-electric expansive device.

INCANDESCENT ELECTRIC LAMP. M. W. Dewey, Syracuse, N. Y., 603,056. Filed July 22, 1891. Comprises a light giving electric conductor, a receiver made entirely of glass and completely inclosing the conductor, and from which receiver the air is exhausted, and an electric conductor outside of the receiver and in inductive relation to the inclosed conductor.

ELECTRIC LAMP. D. Misell, New York, 603,112. Filed Oct. 9, 1897. Consists of batteries and lamp, comprising an electric headlight for bicycles.

Measurements:—

SYSTEM OF ELECTRIC METERING. H. C. Wirt, Schenectady, N. Y., 602,925. Filed Dec. 31, 1897. Combines with the circuit mains, a motor mechanism for registering the consumption of energy, and automatic means for varying the retarding effect of the meter.

HINGE CONNECTION FOR ELECTRICAL MEASURING INSTRUMENTS. A. H. Hoyt, Penacook, N. H., 603,042. Filed Nov. 1, 1897. A thermal registering maximum meter having electrical connections for the stationary and movable parts of the instrument consisting of flexible metal strips.

Miscellaneous:—

PROCESS OF PRODUCING CHEMICAL COMPOUNDS BY ELECTROLYSIS. J. W. Richards and C. W. Roepper, Bethlehem, Pa., 602,872. Filed July 6, 1897. Details of process.

PROCESS OF ELECTROLYTICALLY MANUFACTURING METALLIC SULFIDS. J. W. Richards and C. W. Roepper, Bethlehem, Pa., 602,873. Filed July 6, 1897. Consists in employing an anode containing the metal whose sulfid is desired, in a solution containing a hyposulfite salt and an electrolyte, in conjunction with any suitable cathode; passing a current of electricity therethrough, and precipitating the sulfid of the metallic base present in the anode.

ELECTRIC LUMINOUS ALPHABET AND BOARD FOR SAME. D. M. Moore, Newark, N. J., 602,953. Filed Dec. 17, 1895. An apparatus by which the letters of the alphabet, numerals, etc., may be made to appear as produced by a continuous line of light, consisting of an electric lamp fashioned to represent the desired character instead of being made up of a number of incandescent lamps.

VACUUM TUBE LANTERN. L. Wallach, New York, 602,966. Filed July 20, 1897. A device for holding vacuum tubes so as to produce a satisfactory luminous effect and at the same time present an artistic appearance.

SILICID OF IRON. G. De Chalmot, Leaksville, N. C., 602,975. Filed Sept. 6, 1895. A new product of the electric furnace being ferrosilicid containing upward of 25 per cent. of silicon, and consisting of a mixture in variable proportions of Si_2Fe_2 and Si_2Fe.

PROCESS OF PRODUCING SILICIDS OF IRON. G. De Chalmot, Holcomb's Rock, Va., 602,976. Filed Sept. 6, 1895. Similar to above.

ELECTRICAL RETORT. H. Eldridge, D. J. Clark and S. Blum, Galveston, Tex., 603,058. Filed June 28, 1897. Adapted for manufacturing hydrogen gas from water to be utilized as a fuel for heating purposes.

ELECTRICAL FOOT GEAR. J. Gallegos, Guatemala, Guatemala, 603,135. Filed March 5, 1898. Consists of an insulating insole and a generating insole laid theron, the latter being formed of a fabric composed of woven strands covered with glass beads.

ELECTRO-PNEUMATIC PIANO PLAYER. F. R. Goolman, Los Angeles, Cal., 603,184. Filed May 5, 1897. Details of construction.

ELECTRICALLY PROPELLED VEHICLE. H. G. Morris and P. G. Salom, Philadelphia, Pa., 603,198. Filed Sept. 29, 1896. A front axle having a motor mounted thereon, a forward structure forming part of the vehicle body and located directly above the front axle and carrying the battery, a rear axle, and a carriage body trailing from the front structure and mounted upon the rear axle.

ELECTRIC CLOCK. S. Fischer, New York, 603,232. Filed June 26, 1897. Details of construction.

Railways and Appliances:—

TROLLEY. J. E. Wells, Syracuse, N. Y., 602,923. Filed May 1, 1897. Designed for double track roads having a common conductor wire.

ELECTRIC RAILWAY. C. F. Holtmann and C. Bergmann, Pittsburg, Pa., 603,060. Filed Aug. 5, 1897. Sectional conduit system. Details of construction.

Switches, Cut-Outs, Rheostats, Etc.:—

ELECTRICAL SELECTOR. L. W. Crowfoot and F. E. Granger, Aberdeen, S. Dak., 602,895. Filed Sept. 14, 1897. Details of construction.

RHEOSTAT. R. W. Ney, New Rochelle, N. Y., 603,027. Filed Feb. 5, 1897. Designed for use in connection with electroplating apparatus.

RHEOSTAT. H. W. Leonard, East Orange, N. J., 603,063. Filed July 28, 1896. A support covered by a layer of partially vitrified insulating material, a layer of vitreous insulating material on the layer, and a conductor held to the insulated side of the support by a layer of non-vitrified insulating material.

Classified Digest of U. S. Electrical Patents Issued May 3, 1898.

Alarms and Signals:—

AUTOMATIC ELECTRIC FIRE ALARM. W. E. Frost, Lewiston, Me., 603,270. Filed June 30, 1897. Comprises a case having an air chamber and a concave diaphragm, a circuit closing float supported loosely on the diaphragm, a guide ring of fiber secured within the case, a stationary electrode and circuit wires connected respectively for the float circuit closer and stationary electrode.

ELECTRIC SIGNAL SYSTEM. L. C. Werner, Broad Brook, Conn., 603,369. Filed June 12, 1897. A system for indicating to a moving train its position relatively to the nearest train on such track.

ELECTRIC SIGNAL SYSTEM. L. C. Werner, Broad Brook, Conn., 603,390. Filed June 17, 1897. Similar to 603,369.

Batteries, Secondary:—

PROCESS OF MAKING PEROXID OF LEAD FOR GALVANIC BATTERIES. J. D. Darling, Philadelphia, Pa., 603,361. Filed Dec. 23, 1896. Consists in compressing a mass of peroxid of lead containing free acid, and then exposing the mass to electrolytic action as a cathode in a neutral electrolyte until the superficial layer of the mass has been rendered coherent by the production of inherently formed binding material.

ART OF MAKING PLATES FOR ELECTRIC BATTERY PURPOSES. A. C. Crofton, Chicago, Ill., 603,499. Filed Feb. 5, 1897. A method of forming spongy lead plates, which consists in forcing molten lead through a series of small orifices and allowing it to pile up just before solidifying upon a horizontally vibrating surface.

Dynamos and Motors:—

ELECTRICAL APPARATUS. W. Stanley, Pittsfield, Mass., 603,515. Filed Jan. 28, 1897. An induction motor having two coils in series with each other, and with a source of alternating current, in combination with two shunts, one of less and one of greater time-constant than the coils which they respectively shunt, and a closed circuited armature in direct inductive relation to the fluxes produced by both coils.

Electro-Metallurgy:—

ELECTROPLATING APPARATUS. L. Potthoff, Flushing, N. Y., 603,286. Filed April 22, 1897. Adapted for electroplating metal.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. T. H. Pettengill, Amsterdam, N. Y., 603,283. Filed Sept. 7, 1897. A substitute for the cut-out device of Thomson-Houston arc lamps.

ELECTRIC ARC LAMP. A. W. Knutson, Galesburg, Ill., 603,383. Filed April 30, 1897. A clutch for electric arc lamps having a clutch arm formed with an obliquely disposed rod-opening piercing one side of the arm to permit of the carbon rod passing laterally into the opening, one of the inclined walls of the opening being provided with a clutch notch.

Miscellaneous:—

PROCESS OF AND APPARATUS FOR ELECTROLYTIC TANNING. E. Davis, Philadelphia, Pa., and H. R. Mustard, Smyrna, Del., 603,263. Filed July 27, 1896. Consists in vertically suspending skins in a solution of tanning liquor, simultaneously passing an electric current through the solution perpendicular in direction to the surfaces of the skins, and intercepting the particles precipitated at the anodes by the action of the screen.

ELECTRICAL ATTACHMENT FOR GAS LIGHTS. F. L. Kellner and G. S. Barrows, Philadelphia, Pa., 603,334. Filed Nov. 22, 1897. A device for operating the gas valves to turn on and off the gas and permit of its ignition by means of a pilot light. Details of construction.

ELECTRIC DENTAL ENGINE CONTROLLER. J. J. Coachman, Rio

Janeiro, Brazil, 603,524. Filed Aug. 21, 1897. Embodies a pedal mounted to swing on the base and carrying contacts, a circuit closer mounted on the pedal, and hinged wings carried by the pedal for shifting the circuit closer.

ELECTRIC CONVEYING SYSTEM. A. S. Kortz, Springfield, Ohio, 603,606. Filed Dec. 2, 1897. Adapted for store service. Details of construction.

Switches, Cut-Outs, Etc.:—

TIME LIMIT CUT-OUT. H. H. Cutler, Chicago, Ill., 603,594. Filed July 26, 1897. Comprises an active coil of a cut-out and a time limit controlling it and comprising a section of an electric circuit, the resistance of which varies with rise of temperature due to the current.

OBITUARY

Hugh E. Fitzgerald.

Hugh E. Fitzgerald, superintendent of the Detroit Electric Light and Power Company, met with a bicycle accident on April 27 that resulted in his death at Harper Hospital shortly after midnight.

Mr. Fitzgerald was riding on Grand River avenue to his home at 549 Fifth street. A car drew in ahead of him at Third street, and he veered his wheel to pass behind it. At the end of the car he was struck by another rider who was coming down Grand River avenue at a terriffic rate of speed. Mr. Fitzgerald was thrown to the pavement with terrific force, striking on his head. He lay senseless until picked up by an officer. He was carried into a drug store near by and Harper Hospital ambulance was called. At the hospital the doctors found the injured man had sustained a severe fracture at the base of the skull, and they realized that his death was but the matter of a few hours. Mr. Fitzgerald was forty years of age and had lived in Detroit about 12 years. He leaves a wife and four children between the ages of 7 and 14 years. He was a brother of W. H. Fitzgerald, manager of the Detroit Electric Light and Power Company.

PERSONAL

PROF. I. FUJIOKA, of the Imperial University, Tokyo, Japan, is on his second trip around the world gathering information on the latest electrical developments. The results of Prof. Fujioka's first trip, eleven years ago, are seen everywhere in Japan, the majority of whose electrical undertakings are due to his initiative. Prof. Fujioka intends to remain several weeks in this part of the country, with New York as his headquarters. He is to lecture before the New York Electrical Society at the Electrical Exhibition.

FREDERIC A. C. PERRINE, D.Sc., Prof. of Electrical Engineering, Leland Stanford Junior University, Palo Alto, Cal., received leave of absence for two years from active teaching. The department will remain under his charge, the teaching being done by Mr. Clement A. Copeland, an engineer of the West Side Lighting Co., of Los Angeles, a graduate of Cornell, together with Mr. F. G. Baum and G. H. Maddock, both of whom are graduates of the Leland Stanford Junior University. The company of which Dr. Perrine will be engineer is the Standard Electric Co., of California. This company will buy water power from the Blue Lakes Company, transform it into electric power and transmit from near Mokelumne Hill to San Francisco, a distance of 110 miles. There is available something like 50,000 h. p., but they will begin with a generating plant of 10,000 kilowatts. The plans are not yet formulated, and will not be before the end of the summer. The best wishes of the electrical fraternity accompany Dr. Perrine on his new undertaking.

MR. ROBERT J. PARVIN has taken charge of the New York office of "The Western Electrician," succeeding Mr. W. F. Osborne, resigned. Mr. Parvin is no stranger to the electrical field, having been for some time connected with the Chicago office of our contemporary. We welcome Mr. Parvin to his new field of activity.

REPORTS OF COMPANIES

Consolidation of Telephone Construction Companies.

Mr. J. E. Keelyn, president of the Western Telephone Construction Company, of Chicago, has just closed a deal for control of the Graham Electric Company's telephone and switchboard business as well as all of its patents. It is said this is the fifth concern that has been arranged for in like manner recently. A strong combination seems to be imminent with Mr. Keelyn as president, and a strong financial syndicate backing it.

The General Electric Report.

The weekly financial bulletin issued by J. P. Wintringham contains the following brief analysis of the General Electric Company's Annual Report, printed in our last issue:

"The report of the General Electric Company for the past year is interesting and instructive. It shows that the company earned on the common stock about $1,000,000 over the sum that would pay the preference dividend. This is about 3⅓ per cent., and would make the stock cheap at 31½. It also shows that the book value of General Electric stock is about 57, but this counts the patents at $8,000,000, and they are certainly not worth any such sum. Valueing the patents at nothing at all General Electric stock would be worth 30, and therefore it seems from every point of view, not dear at the present price of 31½."

A Thirty Mile Electric Railway.

Electrical features of unusual interest are to be associated with the new equipment of the Lewiston, Brunswick and Bath Railroad, Maine. The Westinghouse Electric & Manufacturing Company is to furnish the apparatus. Generators to supply alternating and direct currents simultaneously are to be located at Brunswick, Me., the initial installation being 1,000 h. p. Direct current is to be used at the sections of railroad in and about Brunswick, and the alternating current is stepped up to 10,000 volts and transmitted to sub-stations at Lewiston, Bath and Lisbon Falls. Here Westinghouse rotaries transform it to supply their respective trolley feeders. The A. C.-D. C. machine is a Westinghouse product, and is well adapted to work of this kind.

SAULT STE. MARIE, MICH.—The American Lake Superior Power Company is asking for bids for the construction of a water power canal at this place. The canal will be 1½ miles long, 200 feet wide and 222 feet deep. The work is one of great magnitude, involving the expenditure of several millions of dollars. A lease for a 20,000 h. p. engine, to be ready in two years, has been made to the Lake Superior Carbine works. New York and Philadelphia capitalists are pushing the work.

WOONSOCKET, R. I.—Snoqualmie Falls will supply light and turn the wheels of machinery in Tacoma and Seattle. This work is being done by Mr. W. T. Baker, president of the Chicago Board of Trade. Mr. Baker expects to expend between $300,000 and $400,000 in the development of this project.

THE FOREIGN MARKET for American electrical machinery seems to be opening up in a very satisfactory manner. The Sprague Electric Company have recently shipped several direct connected generating sets for isolated lighting plants, as well as a large number of Lundell fan motors to India and Japan.

MR. ALBERT B. HERRICK, consulting electrical engineer, has removed his offices from 150 Nassau street to 120 Liberty street, where he will be nearer his clients and have more space to accommodate an increasing business.

TRADE NOTES & NOVELTIES

The Electrical Exhibition of Philadelphia.

We are in receipt of the following communication from the management of the Philadelphia Electrical Exhibition: "From several different sources the query has come to us whether we were not a branch of the Electrical Exhibition of New York. It is impossible to find out where this rumor originated. It has no foundation whatever. The Electrical Exhibition of Philadelphia happens to follow the New York Exhibition, opening one week after the closing of theirs. The friendliest possible relations which have been in existence for many years exists between the managers of the two organizations. It is hoped that everything that is attractive to the general public shown by the New York company will find a place in the Philadelphia Exhibition. In many respects we shall differ widely from the Exhibition given in New York. We have made special arrangement for the elaborate decoration of our building by our architect, and in this point hope to surpass anything that has ever been done in the past. We have also arranged and well nigh completed an electrical cataract, which is a reproduction of one used with great success at the Opera Ball in Paris. We have secured the kinetoscope, the cinematograph, the X-ray apparatus with a screen will be constantly in operation, an electric fountain with kaleidoscopic effects produced by rapidly moving lights is now being built; arrangements are effected for the use of large quantities of decorative foliage plants in connection with electric lights. While the commercial of the Exhibition, as far as selling on the spot is concerned, will undoubtedly be a feature, we shall be very careful to limit our Exhibition to those purely electrical. We will avoid as much as possible exhibits of allied industries which might be used for other than electrical purposes. We have secured phonographic speeches from distinguished inventors and electricians and these will be given at regular intervals."

Phoenix Glass Co.

Phoenix Glass Company, 42 Murray street, New York, have on May 1 moved into larger quarters located at 15 Murray street, Franklin Building.

Harry P. Barr.

Mr. Harry P. Barr, consulting engineer, removed his offices on May 1 from 120 Liberty street to the Washington Life Insurance Company's building, 141 Broadway, corner of Liberty street and Broadway, room 1408.

Messrs. Baldwin, Davidson & Wight.

Messrs. Baldwin, Davidson & Wight announce the removal of their New York offices from the "Times" Building to 144 Broadway. Their Washington offices, as heretofore, are at 25 Grant place, Washington, D. C.

Rossiter, MacGovern & Co.

Rossiter, MacGovern & Company announce the removal on May 1 of their principal office to the new Washington Life Building, 141 Broadway. Hereafter their entire stock will be carried at their Newark factory and repair shop, 35-37 New Jersey Railroad avenue. Added facilities will enable them to display a large and very attractive stock of every kind of electrical machinery.

Pattison Bros.

Messrs. Pattison Bros. are informing their many patrons that they have removed their offices to 141 Broadway, corner Liberty street.

Westinghouse Apparatus at the Boston Terminal.

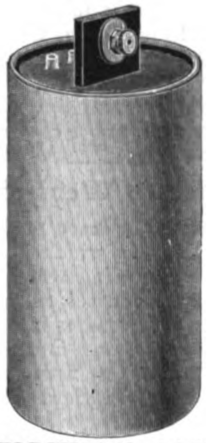
The new Southern terminal railway station at Boston is a good illustration of the scope of the Westinghouse manufactures. The switches and signal system are to be provided by the Union Switch and Signal Company; the engines by the Westinghouse Machine Company; the Westinghouse Air Brake Company will equip the rolling stock; and all the electrical apparatus will be supplied by the Westinghouse Electric and Manufacturing Company. The electric installation is to comprise 1,000 h. p. of dynamos and motors. The station when completed will be the finest in the country. Electricity will be used for lighting, for driving pumps, ventilating fans, etc.

Rapid Development of the Polyphase System.

Within the past three years the Westinghouse Electric and Manufacturing Company has installed over 100,000 h. p. of polyphase generators, ranging in size from 10 to 5,000 h. p. each. Judging from the orders at present on hand, the Westinghouse Company will build more than 100,000 h. p. of this type of generators alone during the coming year. A single order now on their books calls for 75,000 h. p. Polyphase motors have also been made in immense quantities, ranging from 1 to 500 h. p., two of the latter being for the Niagara Falls Electric Light and Power Company, where they are utilized to drive the dynamos for lighting the town, power being supplied to the motors by the 5,000 h. p. Westinghouse Niagara generators.

New Western Electric No. 6 Porous Cup Cell.

The Western Electric Company is placing upon the market a high grade porous cup, the ingredients of which are claimed to be the best that can be obtained. All material is thoroughly inspected before it is used and the recuperative powers of the cell are such that the battery will return to its normal voltage



NEW WESTERN ELECTRIC No. 6 POROUS CUP CELL.

immediately after being subjected to a severe overload. The depolarizing action, due to the pure material used is extremely rapid. All the porous cups are stamped No. 6, and any one asking for a Western Electric No. 6 porous cup will be assured of receiving an article of high grade.

Creditable Showing for Westinghouse Street Railway Apparatus.

Seventy-six double equipments of Type 49, 35 horse power motors, have been ordered from the Westinghouse Electric and Manufacturing Company by the Cleveland Electric Street Railway Co.

Mr. Chas. H. Smith, superintendent of the Lebanon & Annville (Pa.) Street Railway Co., writes: "On June 20, 1895, one of the Westinghouse 12-A 30 horse power equipments was put into service on this road. Since that time it has made 592 days, 200 miles per day, a total mileage of 118,400, without a single repair to any part of the machine, save renewal of brushes and bearings. The motors were put under a Jackson and Sharp 30-foot closed body car, running over the hardest part of the road, with less than five minutes' lay-over at either terminus, from

6 a. m. to 12 midnight. Wish all our equipments were Westinghouse 12-A."

The Chicago Fuse Wire and Mfg. Co.

This company, whose factory was totally destroyed by fire on Jan. 28, is now in better condition than ever before for filling orders for their tested fuse wire and links, which are so well and favorably known by all users of such goods.

The company calls attention to the fact that after the 1st of May all their fuse wire will be packed on the trade-mark spools which they have used for the past five years, and that these spools will in turn be inserted in neat individual tin boxes which will protect the wire from danger of abrasion and also from being affected by changes of temperature.

The company will carry a full stock of all sizes of wire, strip, links, telephone and telegraph fuses, and will make shipments from their factory in Chicago or their Eastern office at 853 Broadway, New York City, as may be most convenient to the trade. Mr. W. R. Goodman, their manager, says the great consideration shown them by all their friends in the trade during a few weeks of enforced suspension of business after the fire is highly appreciated.

Hammacher, Schlemmer & Co.

This firm, located at 209 Bowery, New York, call particular attention in this issue to their line of trimmings for phonograph and other cases and cabinets. These goods are directly in the line of cabinet hardware, in which Hammacher, Schlemmer & Co. are leaders (having been in the business for fifty years), and of which their assortment is unlimited and their stock very complete.

Besides cabinet hardware, their line of tools and factory supplies is of especial interest to manufacturers of electrical machinery, etc. In the line of piano hardware, their German steel music wire appeals directly to the electrical trade. In this wire high tensile strength and absolute uniformity of gauge and temper are pre-requisite and it is just these qualities that make the wire of value to the electrical manufacturing trade.

This firm deals direct with manufacturing consumers and issues a number of catalogues ranging in size from 25 to 400 pages, each applying to a different line of goods. These catalogues are sent gratis to responsible concerns.

Stone & Webster,

This firm announce that they have made arrangements with Prof. S. Homer Woodbridge by which his business of heating, ventilating and sanitary engineering will hereafter be intimately associated with their own electrical engineering work. They believe that there are many advantages in having all the mechanical, electrical and sanitary apparatus for a building designed and installed under the direction of one firm and the above arrangement has been made with this in view. Prof. Woodbridge has taken offices with Stone & Webster at 4 Post Office Square, Boston, and they are now ready to undertake work together.

CATALOGUES.

Electricians' Sheet Insulation Manual.

PROBABLY one of the most useful and interesting books of insulation ever gotten out is now being mailed to the electric street railways and electrical manufacturers throughout the country by the Mica Insulator Company, of New York and Chicago. The book is made up of several pages of reading matter, each one of which, aside from the title and index pages, is descriptive of the "sample of insulation" preceding the text.

The first four pages are given up in describing the company's flexible and extra flexible "Micanite" cloth and paper. The different thicknesses are given and the average break-down test runs from 296 to 439 volts per mill. These "Micanite" insulating cloths and papers are non-absorbent and remain flexible and are made with one, two, or three layers of pure India sheet Mica. The cloth averages 8, 11, and 14 mills in thickness, respectively; while the paper averages 5.8 and 11 mills in thickness, respectively. It is furnished in rolls 16 feet long and 32 inches wide.

Pages from 5 to 10, inclusive, are descriptive of "Empire" cloths and rope and bond papers. The average break-down test of these materials runs from 506 to 936 volts per mill. The cloths are made from specially prepared muslin and canvas, treated with pure linseed oil, and are furnished in sheets two yards long and one yard wide, carefully packed between sheets of plain paper. The papers are made from the finest grades of rope and bond paper, treated with pure linseed oil, and are furnished in sheets 19 x 24 inches, 22 x 34 inches, and 36 x 72 inches. They are 4½ and 5 mills in thickness.

Pages from 11 to 14, inclusive, are descriptive of the new insulations which the company are placing upon the market, viz., "M. I. C. Compound," insulating cloths and papers. The No. 1 cloth is made from specially prepared muslin and treated with two baked coatings of M. I. C. Compound, while the No. 3 is made from the best canvas and treated with three coats of M. I. C. Compound. Each is furnished in sheets two yards long, one yard wide, and carefully packed between sheets of plain paper, the average break-down tests being 654 and 650 volts per mill, respectively. The No. 1 cloth is seven mills in thickness, while the No. 3, which is used for heavy armature work, is 15 mills in thickness. And the M. I. C. Compound rope and bond papers are made from the finest grades of material and treated with two baked coatings of the M. I. C. Compound, furnished in sheets 19 x 24 inches, 22 x 34 inches, and 36 x 72 inches, with average break-down tests of 739 and 859 volts per mill, respectively. Thickness, 4½ and 5 mills.

The flexible "Micanite" plate, Style B, which the company have sold so largely, is described on page 15, and is furnished in sheets 36 x 36 inches, in any thickness from 10 mills up. This material is used for insulating armature slots, armature, magnet, and commutator cores, transformers, etc.

Another new product of the company's is the oiled Asbestos paper, described on page 16, which is made in sheets two yards long and one yard wide. Standard thickness, nine mills; break-down test, 320 volts per mill. This material is usually used in conjunction with the "Empire" cloths. The two combined make a strong semi-fireproof insulation of a very high resistance.

Page 17 is descriptive of the Standard "Micanite" plate No. 1, which is suitable for general purposes. This plate is suitable for commutator rings, armature slots, spools, transformer insulators, etc., and is furnished in plates of any thickness and of any size up to 40 inches square. The average break-down test is 1,012 volts per mill of thickness, the standard size being 18 x 36 inches. The standard sizes are carried in stock ready for prompt delivery.

The "Micanite" plate, which is especially for commutator segments, is described on page 18, and is called No. 2 Special. It is from this plate that the company saw their segments which have achieved so great a success among builders of electrical machinery and railways during the last two or three years. The plates are furnished in any thickness, size 18 x 36 inches, and gauged to a thousandth of an inch. The company claim advantages for this material over the use of India mica, on account of the treatment which the mica has, so as to wear away equally with the copper.

The other part of this handy book is given over to the description of the company's M. I. C. Compound, which is being used so largely throughout the United States. Two important testimonials appear as a finale to this work, which came from two leading builders of electrical apparatus.

The company will be pleased to mail upon application to those who are users of high grade insulators a copy of this manual or book on insulation, and also call attention to the fact that their materials are carried in stock both at New York and Chicago.

The Lunkenheimer Company.

A very complete and handsome catalogue and price list has recently been issued by the Lunkenheimer Company, of Cincinnati, Ohio. This company manufactures the well known Lunkenheimer valve, injectors, whistles, lubricators, oil and grease cups and steam specialties. A number of pages are devoted to illustrations of the numerous medals and awards taken by the Lunkenheimer productions. The catalogue contains 200 pages, embodying a large number of valuable tables and other useful data.

The American Electrical Directory and Buyers Manual.

The first number of the sixth volume of the American Electrical Directory and Buyers' Manual has been received, and does not lack in completeness and usefulness of reliable data. The edition contains alphabetical indexes to advertisers and buyers' finding list, editorial comments, electric light associations, electric light central stations, general information, and a moonlight schedule.

Lundbergs' Electric Light Fittings.

A very attractive and useful catalogue and price list has recently been issued by A. P. Lundberg, Bradbury Electric Works, Kingsland, London, N. The catalogue contains a variety of electrical apparatus, such as switches, wall connections, lamp sockets, cutouts, switchboards, etc. It has a handsome white cover, with a very artistic design in gold and color.

Central Electric Company's Iron-Clad Fan Motors.

A very unique announcement has just been issued by the Central Electric Company, Chicago, Ill. It consists of a folded postal card bearing on one side the address, and an announcement of Okonite products, and on the other side the significant inscription, "A dollar an inch for fan motors put up," meaning that the price of a 12-inch fan is $12, a 16-inch fan $16, etc. On the inside pages are a number of fan motor cuts, and the company's sound advice to their patrons that they can do twice as much work, with four times the comfort and can get two night's sleep in one if they have one of these busy, breezy motors, distributing refrigerated imitations of lake breezes.

The Falls Rivet and Machinery Co.

The Falls Rivet and Machinery Co., of Cuyahoga Falls, Ohio, are distributing a circular illustrating and describing their power transmitting machinery such as shafting, pulleys, couplings, pillow blocks, rigid boxes, friction clutch pulleys and couplings, rope sheaves, floor stands, etc. The circular contains numerous illustrations of these appliances.

WESTERN NOTES

THE managers of the Alley L Road of Chicago, which is now installing the Sprague multiple-unit system, report that as soon as the steam trains are off the line they will be able to reduce their schedule from thirty-eight to thirty minutes, and that they will save in transportation wages alone more than the total depreciation, and will make the old steam service mileage with 15 per cent. fewer cars. They also report that the strains on their structure are noticeably reduced, and that the increase in their traffic has already added quite a percentage to their receipts.

THE WESTINGHOUSE ELECTRIC AND MFG. CO. has sold to the Citizens' Street Railway Company of Indianapolis, a 500 kilowatt, 90 r. p. m. machine of the Westinghouse standard type. The machine is direct connected to an Allis-Corliss engine. It is over compounded 10 per cent., the normal potential being 550 volts.

THE ELECTRICAL EXCHANGE report great success with their new agency of the Midget Upton arc lamp. They have already secured orders for a large number from all parts of the country. One shipment was sent to St. Michaels, Alaska. In addition to the regular line of Midget Upton lamps, the Exchange is putting out a new Midget Upton alternating lamp which is meeting with great success. The Exchange carries a full line of Midget Upton lamps in Chicago stock, and would be pleased to have prospective purchasers call and examine the various samples now on exhibition.

THE CHICAGO EDISON COMPANY'S second-hand department is selling only its own stock, which is drawn from its numerous customers on its Chicago circuits. It has its own repair shop, and all second-hand apparatus is put in the best possible condition before delivery.

THE CENTRAL TELEPHONE ELECTRIC CO., 1123 street, St. Louis, Mo., report that business has been very brisk with them, having installed several large exchanges, and they have created a large demand for their telephone transmitters, as they are now making a specialty of furnishing these goods to telephone exchanges.

THE PAXTON HOTEL, OF OMAHA, NEB., will have an electric light plant; a "Ball" engine, built by the Ball Engine Company, Erie, Pa., supplying the power.

THE GROWING DEMAND for sulphuric acid for storage batteries is being largely supplied by The Grasselli Chemical Company, of Cleveland. They are providing an acid which is especially adapted to battery use. Their facilities for reaching the trade are of the best, owing to their having several manufacturing plants, the principal ones being at New York, Cleveland and Chicago; the main office being located at Cleveland.

THE CENTRAL ELECTRIC COMPANY, of Chicago, are carrying in stock all sizes of double and single, silk and cotton covered magnet wire, up to and including No. 40, and are prepared to meet all orders for these goods.

THE CENTRAL ELECTRIC COMPANY, of Chicago, are introducing a new and very ingenious device for ceiling clusters, consisting of a porcelain block with a metal canopy, which attaches directly to the ceiling and having the sockets embodied as a component part of the fixture. They are furnished in various sizes from two to five lights and are specially designed for street car work. Special circulars relating to this device can be sent on application.

NEW YORK NOTES.

THE SPRAGUE ELECTRIC COMPANY have just received a contract for seven worm-gear drum elevator machines for the Government Printing Office at Washington, D. C. A significant fact is that one machine of this type was ordered two years ago, and the satisfactory service that it gave led to the second order noted above.

THE MAGNOLIA METAL CO. inform us that they have secured a perpetual injunction and been awarded damages against the Nassau Smelting and Refining Company for infringement of their trade-mark "Magnolia." Judge Wallace rules that the assumption of the trade-mark "Mongolia" by the defendants was calculated to deceive the public, and restrains its further use.

THE ELECTRIC ARC LIGHT COMPANY announce the removal of their New York office to 120 Liberty street, the home of the "Pioneer" enclosed arc.

MR. F. H. SCHLESINGER, 220 Broadway, New York, representing the Peru Electric Mfg. Co., of Peru, Indiana, informs us that his trade in China insulation, also batteries, for many months past has been very satisfactory and their factory running steady on orders.

SCHMIDT & BRUECKNER, 289 Greenwich street, New York City, will soon put on the market an improved arc lamp of the enclosed type, which for simplicity of mechanism is unequaled, it is claimed. It is likely to make a sensation. The firm report that their telephone business has increased so rapidly as to necessitate the devotion to it of further floor space in their factory.

NEW ENGLAND NOTES

THE WHITIN MACHINE COMPANY, of Whitinsville, Mass., have just completed a new casting shop which will be entirely fireproof. It is furnished by The Berlin Iron Bridge Company, of East Berlin, Conn.

A DIRECT CONNECTED ELECTRIC LIGHT PLANT is being placed in the Exchange Building, Boston, Mass. The engine is supplied by the Ball Engine Company, Erie, Pa., and the dynamo by the Westinghouse Electric and Manufacturing Company, Pittsburg.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., have just completed for the Conway Electric Street Railway Company, at Conway, Mass., a steel bridge to carry their electric line across the Deerfield River. This bridge is about 300 feet in length.

ADVERTISERS' HINTS

UEHLING, STEINBART & CO. have removed to 42 Fourth street, Carlstadt, N. J., where they are better prepared to fill their orders for the instruments which have made this firm so well known.

MATHIAS KLEIN & SON advertise tree climbers.

THE C & C ELECTRIC CO., 143 Liberty street, New York, repeat their invitation to inspect their exhibit at the Electrical Show.

THE GOODYEAR VULCANITE CO., 568 Broadway, New York, manufacturers of hard rubber goods of every description, wish it understood that they are not connected with any other firm.

THE SPRAGUE ELECTRIC CO., New York, offer Lundell 12-inch desk fans for all voltages up to and including 230 volts.

I. P. FRINK, 551 Pearl street, New York, are selling a Parisian novelty consisting of silk and velvet shades of fleur de lis pattern for incandescent lamps. They have them in a variety of colors.

R. THOMAS & SONS CO., East Liverpool, Ohio, call attention to the 60,000 volt tests made on the Boch glaze filled high potential insulators at their booth at the Electrical Show.

THE NEWTON APPLIANCE CO., 120 Liberty street, New York, have a complete line of push button flush switches. They also have wood mats to install them with in different colored woods.

WM. ROCHE, 259 Greenwich street, New York, say there is no cut in the prices of the "New Standard" dry batteries.

CASS & AARON, 141 So. Clinton street, Chicago, repair all kinds of electrical machinery and apparatus and offer some bargains in motors, dynamos, meters, etc., all ready for immediate delivery.

THE POPE MFG. CO., Hartford, Conn., are building all styles of electric carriages.

DESK AND CEILING FANS for alternating current are advertised by the Emerson Electric Mfg. Co., St. Louis, Mo.

THE PHOENIX GLASS CO. have removed to 15 Murray street, New York, where they are carrying a full line of shades for every conceivable kind of lamp.

THE WARD-LEONARD ELECTRIC CO., Bronxville, N. Y., are working day and night to keep up with the orders for their circuit breakers and rheostats. The reason for it is the prices at which they are selling them, some of which are quoted in their "ad" this week.

THE WESTERN TELEPHONE CONSTRUCTION CO., Chicago, Ill., state that they are in every way in a better condition than ever before. They also have a word to say about their recent court decisions.

THE DEARBORN DRUG AND CHEMICAL WORKS, Chicago, Ill., who make it a specialty to prescribe a boiler compound to suit each case say: "There are four of our chemists and some forty of our salesmen who draw twice the salary and forget more in ten minutes on this subject than three-fourths of the cheap operators of the electrical plants who are so wise and afraid to spend a few dollars for a reliable preparation."

THE INSULATING SADDLE STAPLE CO., Brockton, Mass., are manufacturing a staple for use in all kinds of interior wiring, a feature of which is a lining of fibre on the inner side of the arch.

H. B. COHO & CO. are now located at their new quarters at 30 Cortlandt street, New York.

THE ELECTRICAL EXCHANGE, 166-174 South Clinton street, Chicago, publish a revised list of apparatus which they offer at bargain prices. They will send their bulletin on application.

THE WESTINGHOUSE MACHINE CO., Pittsburg, Pa., say that their Westinghouse compound made the world's record for economic duty of non-condensing engines and that it has never been beaten.

THE HIGH TENSION STORAGE CO., 1215 Filbert street, Philadelphia, Pa., illustrate some of the applications of their batteries.

THE WAGNER ELECTRIC MFG. CO., St. Louis, Mo., call attention to the deadbeat action of the Wagner voltmeter.

HUNTER FAN AND MOTOR CO., Fulton, N. Y., mention the details of the 1898 Tuerk ceiling fans—alternating or direct current.

THE MONARCH MFG. CO., 39 Cortlandt street, New York, announce that by simply pressing a button an engine may be stopped, any valve in the steam pipe may be closed, or anything may be stopped controlled by valve or lever. Of course this is accomplished by the "Monarch" speed limit.

The Electrical Engineer.

Vol. XXV. MAY 19, 1898. No. 524.

MISCELLANEOUS

The Andreoli Commercial Ozonisers.

M. EMILE ANDREOLI, of London, whose work in the domain of ozone generating apparatus has already been mentioned in The Engineer, has devised two new kinds of ozonisers. The first is a medical and sanitary apparatus in the form of a vacuum tube, containing a metallic rod and surrounded by an aluminum armature. When the current from a Ruhmkorff coil or from a 3,000-5,000 volts transformer is sent through it,

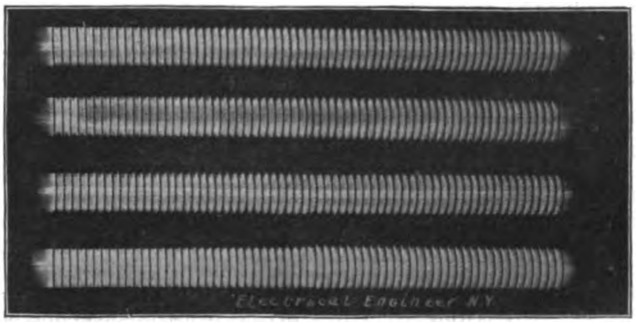

FIG. 1.—LUMINOUS TUBES PHOTOGRAPHED IN DARK ROOM WHILE WORKING.

the tube becomes luminous and ozone is generated round it. These small ozonisers for domestic purposes are most compact, elegant and efficient for sanitary, disinfecting and medical purposes.

Fig. 1 shows four ozonising tubes, taken in a dark room; this set of open ozonisers is actuated by the current from a transformer which raises the current supplied from the street mains from 100 volts to 4,000 volts.

Eminent physicians, well known in England and abroad, have prescribed ozone in many cases. Ozonised oxygen insufflated on wounds produces a remarkably beneficial action. Ulcers which had resisted every other treatment began to heal at once, and the wounds rapidly filling with healthy tissues. In rooms it purifies the air. Many consumptives have been cured by in-

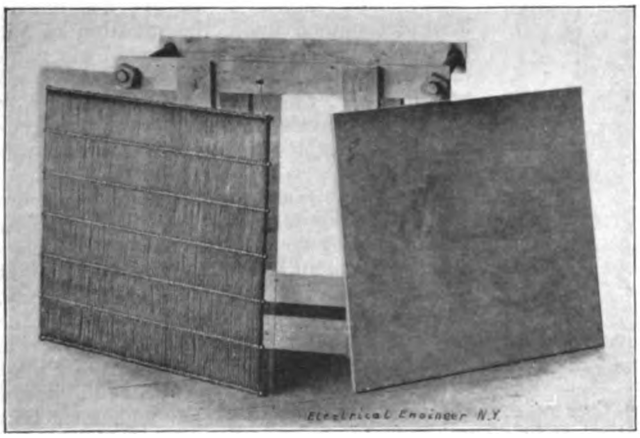

FIG. 2.—FRAME WITH SHEET OF DIELECTRIC AND FLAT ELECTRODE, 2 x 2 FEET.

halation of ozonised oxygen. The essential point is not to administer ozone in extremis. Some examples of the efficacy of these ozone inhalers are reported in the "Lancet" of the 9th of May, 1896, and the "British Medical Journal" of the 10th of October, 1896, where two physicians tell how they treated patients with complete success, in cases of anaemia and other diseases, simply by employment of the ozone of these luminous tubes.

In his "Researches on Tuberculosis," which won the Weber-Parkes Prize Essay in 1897, Dr. Arthur Ransome, M.D., F.R.S., speaks of the treatment by means of ozone and says that with the ozonisers here described great benefit was generally derived by the patients, and although gratifying results had often been obtained from other treatment, he did not remember any that were quite so satisfactory as in those cases in which the ozone was also used.

The second kind of ozoniser devised by Mr. Andreoli is extremely interesting from an industrial point of view. It consists of grids formed of aluminum serrated wires and of flat aluminum electrodes (Fig. 2). These are kept separated by sheets of glass and the whole of the plates and grids are held together by means of wooden clamps. Their construction is extremely simple. No skilled labor is required either to make an installation or to

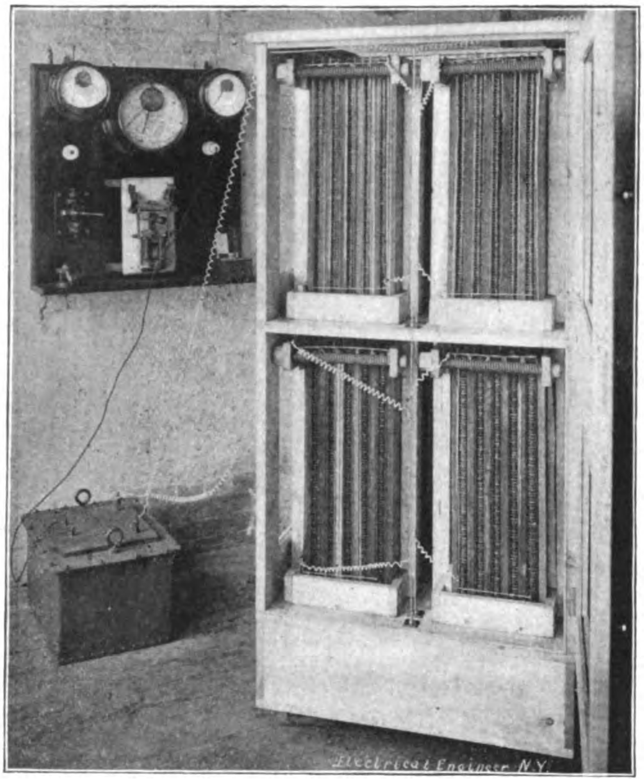

FIG. 3.—EIGHT SETS OF ELECTRODES IN CASE MOUNTED IN PARALLEL.

superintend it. There cannot be any uncertainty or disappointment about the regular working of an installation, however large it may be, since if a given quantity of ozone is produced by a given surface of electrodes of an ozoniser with a given expenditure of electrical energy per hour, we know accurately how many similar ozonisers will be required to obtain a desired quantity of ozone in any time.

These commercial ozonisers produce about 125 grammes of ozone per kilowatt, and are the best for industrial applications. They can be adapted to large installations, and supply ozone at something like $1 per 11 pounds.

The special features of this ozoniser are that the yield of ozone is increased very considerably. There is no circulation of water for cooling purposes. The generation of excessive heat by the electric action on the dielectrics and electrodes is avoided. The electrodes of this form of ozoniser are point-bearing grids facing flat electrodes. The point-bearing grids are composed of a number of serrated wires mounted on rods running through them and kept separated by washers.

Fig. 2 shows one of the grids. There are 80 rows of serrated

wires each having 222 points, making a total of 17,760 on both sides. This shows how, with a moderately high frequency and a low tension, it is possible to obtain a feebly luminous glow and discharge sufficient to bring about the formation of ozone without the production of nitrous compounds or rise of temperature which would affect the yield of ozone. The flat electrodes are made of boards of wood, which are plane and true, and on the two sides of which are fixed thin sheets of aluminum. In this way perfectly even and plane plates at a moderate cost are obtained. Instead of metal sheets, layers of metal can be obtained by electro-plating. An insulating material such as glass is used to separate the electrodes.

Fig. 2 represents one of the grids with a glass sheet behind it, which serves to separate the grid from the flat electrode. It

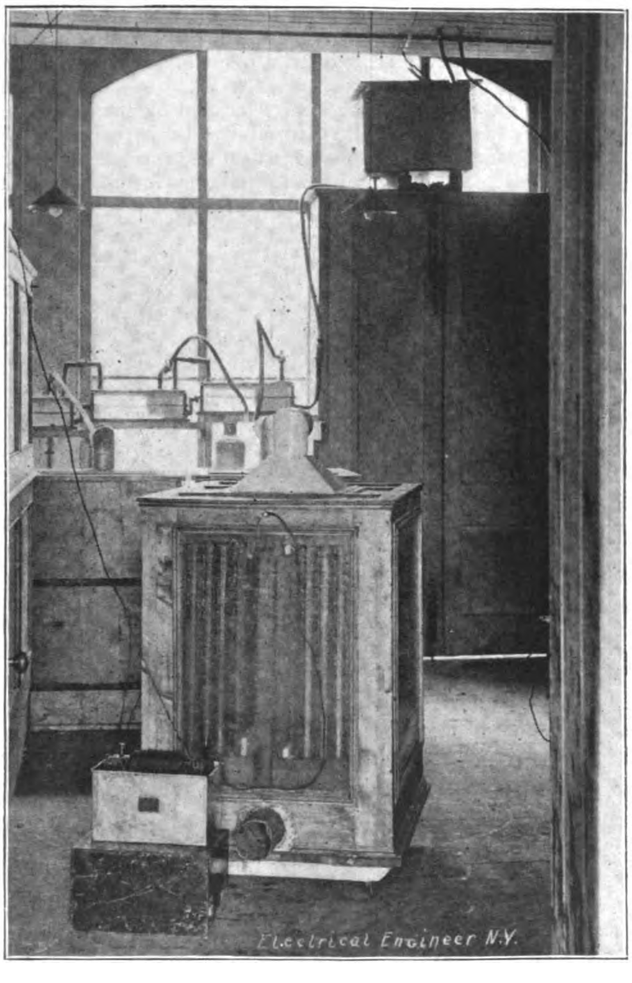

FIG. 4.—OZONIZER, 160 SQ. FT. OF SURFACE, WITH TANKS FOR STERILIZING WATER.

is placed against a wooden frame, which is coated with some insulating material, and which serves to keep the dielectric plates and electrodes together. Next to this is a flat electrode 2 x 2 feet.

Fig. 3 shows an installation consisting of eight sets of electrodes in a case, mounted in parallel with switchboard and Crompton transformer. Fig. 4 shows a type of ozone generator with 160 square feet of surface; in the background are shown a series of tanks for sterilization of water experiments.

The uses to which ozone can be applied are almost without limit. We need only mention a few, among them: Bleaching; ageing of wines and liquors, purification of oils of all kinds, vinegar making, seasoning wood, sterilization of water, etc.

The ozonisers described above are now regularly built by the Electric Ozone Syndicate, Ltd., under the Andreoli patents.

MR. G. ROLF, one of the departmental managers of the firm of Scott & Mountain, of Newcastle-on-Tyne, England, who built the pumping plant for the large floating dock at Havana, is on his way home via New York. Mr. Rolf is making a tour of inspection of the latest American lighting and power stations in this section.

Electricity in the Mackay Mausoleum in Greenwood Cemetery.

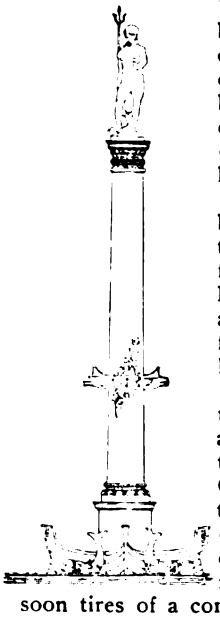
One is hardly accustomed to look for cheerfulness in connection with anything associated with the dead, but that electricity can be made to go a great way towards making the tomb a place of rest and comfort to the mourner in all weathers and at all seasons of the year is fully demonstrated by the unique installation recently completed in the Mackay mausoleum in Greenwood Cemetery, Brooklyn, N. Y.

The interior of this beautiful structure is lighted by sixty 10 candle power incandescent lights placed at the base of the dome roof, and hidden from view by a heavy marble cornice. The lamps are set in a horizontal position, and below them is a special, white enameled copper reflector fitted to the base of the dome in such manner that the light is reflected to the dome which is decorated with Venetian mosaic work. In this manner the whole of the interior of the mausoleum is thoroughly lighted without any shadows, there being a perfect diffusion of light, and a very pleasing effect.

The heating and ventilation is accomplished by a series of heater plates taking a current of eighty amperes at 220 volts, installed in four series of 20 amperes each, so that any desired temperature can be obtained according to the requirements of the weather. There is in connection with this electric heater a nine-inch air duct leading in from the outside of the vault; through this is drawn in a current of fresh air which in passing over the heated plates gives a constant supply of pure warm air to the interior of the mausoleum. The foul air passes out at the top of the dome, thereby completing the system of perfect ventilation for the interior. The heating apparatus is sunk in the centre of the mosaic floor and covered by a handsome bronze grill work flush with the floor.

The lighting and heating is controlled at the panel and distributing board set flush in one of the black Belgian marble panels inside the mausoleum, which is enclosed in a handsome bronze frame and marble door. The whole of the electric work was designed and installed by Messrs. Zimdars & Hunt, of New York. The current is furnished by the Brooklyn Edison Co., from circuits fed from their new Bay Ridge Union Station.

The Electric Fountain "Nautilus" at the Transmississippi Exhibition, Omaha.



T may be taken for granted that no exhibition of moment is now projected without embodying in its plan a fountain of one description or another. The Omaha Exhibition is no exception to this rule; on the contrary, a water scene including a fountain display may be said to be the most prominent landscape feature of the entire Exhibition.

The main features of the grounds having been determined upon, the question of the type of water display to be adopted was carefully considered, and the result is the "Nautilus" fountain, which in beauty of conception and in size rivals anything which has thus far been attempted in electrical work of this kind.

The Omaha fountain is distinguished from that which was installed at the World's Fair at Chicago, by the fact that, whereas the latter was a luminous fountain, the one at Omaha is electrically lighted; that is to say, there are no submerged lights. While the electrical self-luminous fountain is one of display and effect and in the nature of a play, it must be operated at intervals, as the public soon tires of a continuous gaze at one object, no matter how beautiful or brilliant it may be.

An electrically lighted fountain, on the other hand, such as that at Omaha, is more on the order of a natural display and in this case serves the double purpose of a further embellishment to the grounds and may be kept in play at all times both day and night, without in the least causing the observer to tire; indeed, it will prove restful to the sightseer.

The general plan of the arrangement of the fountain is shown in the accompanying illustrations. The fountain is the principal

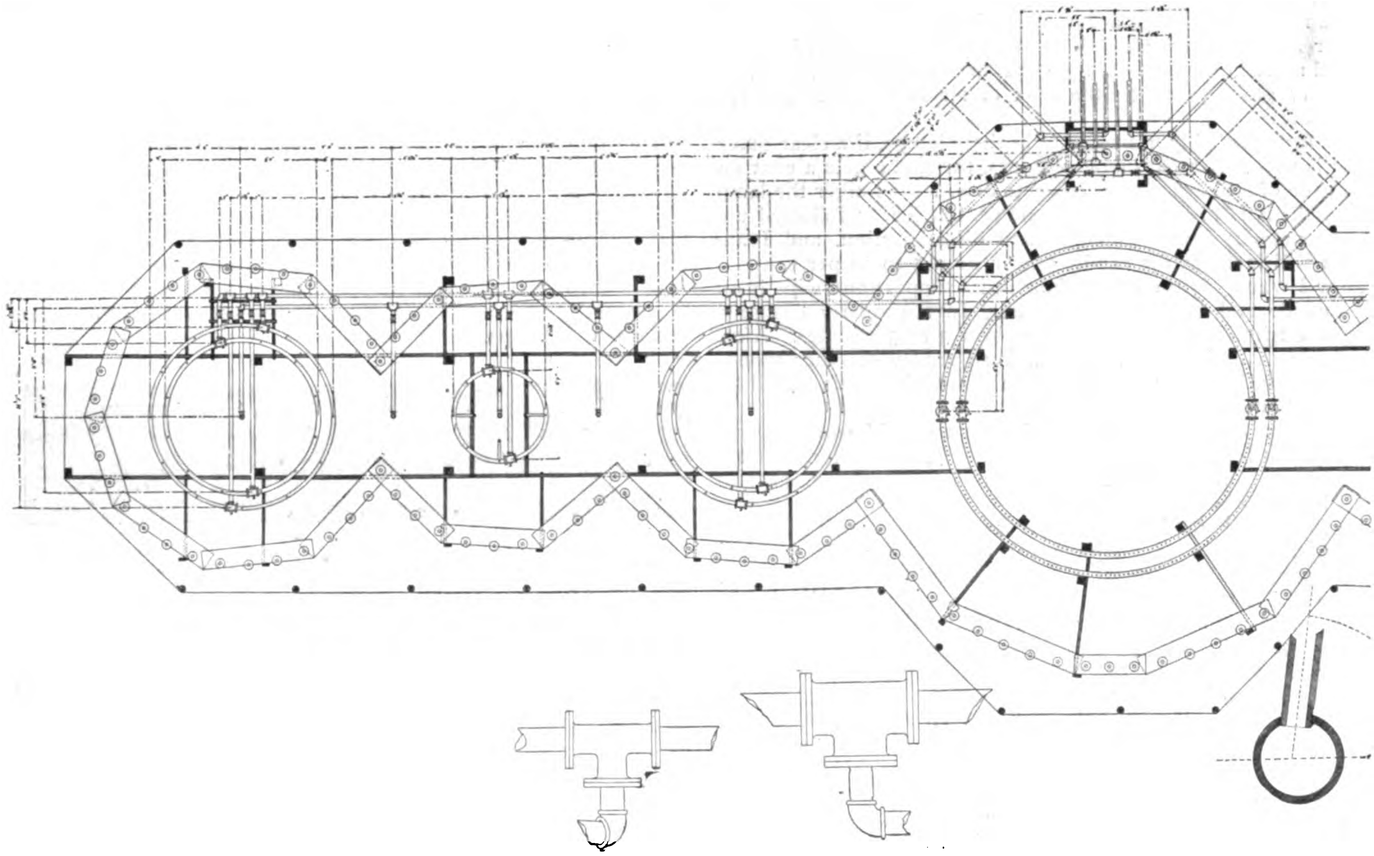
feature of the lagoon, which is half a mile long and about 400 feet wide, and around which the principal buildings of the exhibition are grouped. One end of the lagoon on which the United States Government building borders opens out in the shape of a clover leaf at one end of the Grand Court, and in the centre of this clover leaf stands a beautiful, classical shaft surmounted by a figure of Neptune, shown at the head of this article.

For a distance of 60 and 70 feet on either side of this column hundreds of jets, slightly protruding from the surface of the water, eject their streams in fanciful forms and figures in harmony with the surroundings. Where the spray and jets strike the water a border of incandescent lamps in various colors, and embodied in the form of lilies, seemingly float on the water. Immediately surrounding the column at its base are two concentric circles, the outwardly directed jets of which form a hedge-like enclosure, symbolic of Neptune's captivity. On either side of these rings are two additional rings, one of parabolic jets, and one with a central geyser; beyond that are a series of ring jets and a setting of pyramid jets, and centrally a large geyser. At the two extremes there is a similar arrangement which flanks the main column on either side.

The fountain proper forms a series of slightly intersecting circles, and following the curves of these circles is a continuous border of incandescent fancies in the form of floating water lilies. The fountain proper will be flooded with light from points of vantage by means of searchlights and so arranged that the source will never be in the line of sight of the spectators.

The supply of water is derived from the city water works, the water being led out into the lake from the Government Buildings, where the water controlling valves are installed. After expending its pressure for the fountain the water serves to replenish the evaporation of the lake. The entire piping jets and frame work are supported on piling sufficiently submerged to conceal all evidence of construction; only the protruding nozzles or jets disclose the presence of a fountain when in operation.

The fountain is original in its conception, and adapted specially to the favorable conditions that the site affords. It is from the designs of Mr. Luther Stieringer, consulting engineer. The working details and the entire construction were carried out by Mr. Henry Rustin, electrical engineer, with the assistance of the Exhibition staff, and the results attained will be largely due to the fidelity and interest shown by the latter in carrying out the plans.



PLAN OF ELECTRIC FOUNTAIN "NAUTILUS," AT OMAHA, SHOWING ARRANGEMENT OF PIPES AND VALVES.

ELECTRIC LIGHTING

Trimming and Cleaning of Enclosed Arc Lamps.

BY J. H. HALLBERG, E.E.

THE trimming and cleaning of the inner globes of enclosed arc lamps is of the utmost importance, as the efficiency or candle power depends, to a large extent, on the transparency of the inner globes. It is a very serious matter and well worthy of careful consideration. My object is to suggest to the reader a system for doing this work, which will save many inner globe "kicks" from customers, and save carbons and labor; it may be applied to any size plant.

The following suggestions are based on the claims that one 12x½ inch solid carbon will burn 125 to 150 hours, and apply to all enclosed arcs except the alternating, in which are used various sizes of carbons, some lamps using one solid and one cored, others two cored carbons, and there may be alternating current lamps that use solid carbons in both top and bottom, but as yet are not advertised in this country.

Let us suppose I am manager of a lighting plant, and a number of enclosed arcs have been put in service for either commercial or street lighting, and it was required to get up a system of trimming and cleaning of these lamps; I would proceed as follows:

I would first make a box of tin or zinc about 18 inches long by 13 inches wide by 6 inches high, and space it off so as to get room for 13 inner globes, 25 or more upper carbons, 25 or more lower carbons, 25 stubs of carbons left in upper holder after 125 to 150 hours' run, 25 stubs of burned-out lower carbons, and one space for a few small repairs, tools and rags for wiping.

I would cover the inside (bottom) with 1-16-inch thick asbestos, which will prevent the chipping or breaking of the inner globes when they are placed in their spaces. I would attach a

strong strap to this case for carrying same and get an oil-cloth, or similar goods, to cover the globes and carbons in rainy weather, as dampness on carbons and inner globes has a bad effect on enclosed arc lamps. Then I would buy one extra inner globe for each lamp, as many carbons as I would need for one year, and a few screws, etc., that are liable to get lost or damaged during burning or trimming.

When time comes for retrimming of lamps, I would place 12 clean inner globes in their respective spaces in the box, leaving the 13th space empty; 25 upper carbons, 25 lower carbons in their spaces, and a few of the small screws, etc., with tools or rags in their space; now all spaces but three in the box are filled. I put on a pair of gloves, pick up my box and ladder, and start to trim, as follows:

First shut off current if lamp is burning or not, lower outer globe, take out dirty inner globe, place same in the 13th space in box, remove carbons left in upper and lower holder, and place them in their respective spaces; place new upper carbon in its holder (firmly) and try it up and down slowly to insure against binding; place new lower carbon in its holder, being sure no broken piece is left in bottom and that carbon is down as far as it should go; put on clean inner globe and lift clutch up so as to see that everything works right.

Take a rag and wipe any part of lamp that may be dusty or dirty and reach down and wipe out the outer globe, as there is always more or less dust accumulated in it, either from the outside or from the arc enclosed in the inner globe; this latter is noticed more in the type of lamps that are designed to depend on the outer globe to check the inlet of air in order to get 150 hours' life.

You have probably noticed that in these lamps, if a clear outer globe is used, after 100 or more hours, the globe gets a coat on the inside of a bluish film which gets denser the longer the lamp burns. This is probably a small thing, but if it is followed up, it may prevent some "kicking" and dissatisfaction, and I am sure it will increase the candle power from 5 to 10 per cent.

Now I would set the outer globe in its support and wipe it on the outside and turn on the switch. In a properly designed lamp the trimming should not take over 3 to 5 minutes. After trimming 12 lamps I would get a fresh supply of inner globes and carbons, leaving the old ones in the station; this would be continued until all lamps were trimmed.

Now I have a system of trimming that should work to perfection with few minor changes to suit local conditions; and I also have a number of burned top and bottom carbons and dirty inner globes.

I will first rig up for cutting the carbon pieces left in upper holders for use in next trim lower holder. I would make a simple gauge of some metal, the exact length marked on tag of lamp, and cut my carbons with a hack-saw or a pair of shears, which I prefer, to this gauge, always taking care to get the size within 1-16 inch; this is of much importance. Next, I throw away what is left of the lower carbons, as they are worthless.

My next move will be to clean the dirty inner globes. In looking them over I will find most of them are covered with a grayish-white dust or film on the inside, which comes off if the globe is washed in clean water; but I will also find some that after they are washed in water, show a brownish-black stain around the top of the globe which apparently will not come off, no matter how much it is washed; in fact, it seems as if it was a natural color in the glass itself.

This is not the case, it is caused by several things; the most common cause is impure carbons, which contain too many metallic substances; by the lower carbon being too long, which in turn brings the arc too near the neck of inner globe; or it may be caused by too much current flowing across the arc, especially during the few minutes after trimming lamp with new carbons which causes an excessive flame that gets in contact with the globe and in that way stains it. There is to my knowledge only one way to clean a globe in this condition, and that is by dipping the burned part in hydrofluoric acid. This acid is very dangerous to handle and much care should be exercised when it is used. As this acid will eat through most every material except lead and wax, it must be kept in a jar of that material. I prefer lead, as the acid gets warm when it acts on the glass, and I have seen cases where the wax melted and let the acid run out.

Now construct a round lead vessel about 6 inches high by 3½ inches in diameter (inside). Make this out of an ordinary lead pipe about 3½ inches diameter; after cutting it off, set it in clay or something similar, and pour melted lead in the bottom so as to form a bottom-side about ½ inch thick; be sure it melts together with the pipe and makes a good tight joint. Do not solder this bottom, as the acid will eat out the solder.

Now buy one pint of hydrofluoric acid and put enough in this lead vessel to cover all but ½ inch of the inner globe when it is inserted. The hydrofluoric acid is put in special prepared wax bottles, and must be handled carefully, especially in very warm places. If any acid should get on the hands, it is well to wash them in water at once and apply pulverized soda or something similar; it is well to have something of that kind on hand at all times.

Select a place for this cleaning where a draught can be created to carry off the gas fumes and, if possible, constantly running water; if running water cannot be obtained, get two large tubs of clean water, and next, boxes with perforated bottoms spaced off for about 25 globes each.

After selecting the stained globes, put on a pair of rubber gloves and commence work. First dip part of globe that is burned in acid (this will only take about 1 or 2 seconds in ordinary cases) then give it a liberal bath in the first tub of water. Now we may find a light white film on the globe which can be wiped off with a rag, and then dip in the second tub of water. After this, place it in the box with the perforated bottom; after the box is full take it to some warm place, say on top of a radiator, steam pipe, boiler, etc. After an hour the globes will be as good as new; perhaps some may need a little cleaning with a rag.

Some people advise, in place of using the acid in the manner above described, to use 10 parts of water to 1 part of acid, and place the globes in this bath; this method takes at least 10 minutes, and if several globes are in the bath at once, the chance of breakage is increased 50 per cent.

My method is perfectly safe and very efficient, if the above directions are followed as nearly as possible. The above suggestions may be old to many of my readers, but for those to whom they are unknown they will prove a means of overcoming a difficulty which has been experienced by all who operate enclosed arc lamps.

TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work—X[1].

BY A. E. DOBBS.

UNDERGROUND CABLES.

IT sometimes happens, even in small towns of 1,000 subscribers or less, that a new company will find in certain districts, so many poles and wires belonging to railroad, power, electric light, telegraph and other companies, that the least troublesome method is to put the cables underground. In some places, digging in unpaved back alleys is easy, and the work may be even as cheap as a heavy pole line, with the necessary span wires, slugging and guying.

Of course if the digging is hard, and pavements have to be torn up; that is another matter.

The cheapest duct, and about as good as any, is a creosoted wooden pipe. It needs no cement to hold it in place, for the dirt can be simply thrown back and tamped down on top of it. It will last a great many years, or at least, will not wear out in an ordinary lifetime. The joints should be sealed up with tar, or wrapped with burlap, to keep out dirt and water. In sections where lumber is cheap, a number of ducts can be "built up" in sections three inches square of plain rough inch or inch-and-a-half lumber, which may be tarred or painted. Do not fasten the cable in with pitch if you ever expect to draw it out again. If this kind of conduit is used, however, iron pipe should not be used in connection with it, unless sure that it will be perfectly free from illuminating or sewer gas as well as electrolysis. Many manhole explosions in cities can be traced to this cause. This is not to be taken as condemning iron pipe, but means that ducts exposed to gases should be either all of non-conducting, or all

[1]The writer wishes to acknowledge indebtedness to the Standard Underground Cable Co., of Pittsburg, Pa., and to John A. Roebling's Sons Co. for some of the suggestions contained in this chapter.

of good conducting material, to prevent a difference of potential and sparking between the cable and the duct tubes.

Suppose for example, we have several thousand feet of cable in wooden or tile ducts. Now, this duct being in the ground and more or less damp, would allow a certain amount of leakage to take place, so that if all the cables are connected together, a generator tried on the lead covering would show a very good ground, but this ground extends pretty equally over the entire system—for if a single cable were tried it would test "open"—and distributed in this way it is a very good thing as it clears out the static charge. It also prevents sneak currents from getting in, by interposing such a high resistance that they cannot get there in quantities in any one spot to do any harm.

Now, it often happens that at a manhole a cable is taken up a pole, or side of a building, and on account of its convenience in bending, an iron pipe is used. Suppose, now, as often happens, that the manhole gets just enough gas in it to become as explosive as gunpowder, and only requires a spark to set it off. Suppose again, that the lead covering of the cable receives a static charge from the overhead lines, or a back current from a street railroad track, or a cross with an electric light wire outside. With wooden or tile ducts it would distribute itself equally and harmlessly over the entire system, but with an iron pipe affording a fairly good ground, the visiting current goes that way with a rush, and as the inside of the pipe is apt to be more or less dirty and rusty, there will be just resistance enough to make a spark, and then—explode! If any of my readers have ever seen a manhole cover weighing 500 pounds and fastened down with heavy iron bolts, rise up in the air and land on the roof of a four-story building, I am sure they would consider this kind of a thing worth guarding against.

If all the ducts were of iron, it would also distribute itself probably without sparking, for the resistance of the lead cover to any but the heaviest currents is practically negligible, so that if the cables are all connected together, as they should be, the potential of the whole system is practically equal. But iron pipe exposes cables to stray currents and electrolysis from the trolley roads, and while there is a great deal of iron pipe used, I do not think its use is to be commended. There are iron pipes made with a glaze on the inside, and others lined with cement, but I cannot be convinced that they are as good as wood or tile.

The best but most expensive conduit now being laid is of tile or terra-cotta, with a smooth glaze on the inside.

It is never troubled by electrolysis, is a fairly good insulator, and never decays—though in cities where streets and alleys are continually torn up this is a doubtful quantity.

In order to make good work it needs to be laid in cement; though this depends somewhat on the nature of the soil. Conduits are also sometimes formed entirely of cement, the ducts being formed of paper or sheet iron tubes, and as its only use is to hold the form till the cement can set, it does not matter how long these frail tubes last. The size of the duct should not be smaller than 2½ inches, and 3 inches is better still. A tube that fits the cable too closely will be troublesome when drawing in, and a very little dirt may cause it to stick altogether. The duct might be made larger than this with the idea of carrying two or three cables, but this is not a very good plan, as all the cables would have to be pulled through at the same time; for another cable cannot be pulled into a duct after one has already been inserted. But there is no necessity for pulling two telephone cables into one duct if ducts enough are put down in the first place.

Always make allowance for four times as many ducts as you think can ever be used, for it costs no more to dig a trench for ten ducts than for three, and the only extra expense is for the tube itself. Besides, it may become necessary to change the cables some time, and in such a case an extra duct is very convenient.

It will not do to forget that with cheaper service the time will come when a telephone will be placed in every house, and while planning underground work, make the conduit capacity equal to the number of householders in that vicinity. Even with the high rentals prevailing in New York City, the conduit capacity in some districts has fallen far below the requirements, although at the time they were laid it was supposed there would always be some of them vacant.

In the early days of electric lighting in New York, Mr. Edison planned his system with the idea of supplying every house with light. This at the time seemed like planning a long way ahead, but in less than ten years even his far-sighted engineering proved inadequate, and his feeders had to be reinforced.

Why, in some Western towns where competition has cut the price of party lines down to $1 per month, half the houses in town already have telephones, and even farmers are waking up to the great convenience of this instrument, and some of my acquaintances are beginning to cater to this class of business.

All underground cables should have an alloy of tin in the lead covering, the amount being about three or four per cent. This applies to aerial cables as well, as pure lead, which is sometimes used, is too soft, and inclined to "creep;" but the real object of the alloy is to prevent corrosion. Sometimes the tin is put on the outside as a coating instead of mixed as an alloy. Customers can take their choice.

Bi-Metallic Wire on the Pennsylvania Railway Telegraph System.

The Pennsylvania Railway system has achieved, by careful management, the reputation of being one of the greatest railway systems of the world. Its splendid position is, no doubt, due to the careful consideration which has been given to many apparently minor details, resulting in the general good service for which this system is noted. Outside of the actual roadbed, building and maintenance of bridges, structures, etc., perhaps the most important adjunct to a railway line is the telegraphic service. Even though a superior mechanical system of block signals be in service, it is quite impossible in these days to operate a railway with certainty and despatch without the use of the telegraph. Hence it is that the telegraph plays an important part, and, because of its vital necessity, it is of the greatest importance that the lines should not only be well built, but should be built with the object of staying up, even under extraordinary stress of weather.

Mr. A. M. Schoyer, Superintendent of Telegraph, Pennsylvania lines west of Pittsburg, about a year ago placed bi-metallic wire in service on several of the branch lines of this great railway system in and around Pittsburg, and, because of the very satisfactory service which that wire rendered, he has recently introduced bi-metallic wire on the main line of the road between Pittsburg and Columbus, the size of the wire being No. 9, B. & S. gauge.

The splendid position of the Pennsylvania system to-day shows conclusively that the utmost care is exercised in conducting all branches of its business, and, because of the excellent service which that system renders to the public, it necessarily follows that any material which is used by it receives the stamp of approval of a company which is second to none. In view of this use it can be said that bi-metallic wire is now a standard type of wire for overhead construction.

A Simplification of the Marconi Receiver.

DR. H. RUPP, of Stuttgart, has made an important simplification in the Marconi receiving apparatus, which he describes in the "Elektrotechnische Zeitschrift." To restore the resistance of the coherer, Marconi, as is well known, employs an electric tapper, working like the hammer of an electric bell. This taps the coherer tube, loosens the filings and stops the current. This contrivance has been found to be somewhat uncertain in its action, and when a Morse instrument was used the dots and dashes were often not sufficiently separated.

Dr. Rupp dispenses altogether with the electric tapper in his

FIG. 1.—THE COHERER IN SECTION.

arrangement, and decoheres the filings by causing the tube to rotate on its axis. The rotation of the tube is produced very simply by means of the paper ribbon of the Morse instrument. The leading-in wires of the coherer are mounted in bearings, and a small vulcanite pulley, with flanges, is fixed on one end of the tube. The tube is put in circuit by two small copper springs, which rub on the rotating axes. The paper strip of the Morse instrument passes round the pulley between the flanges.

Fig. 1 shows this coherer partly in section. The paper spool of the Morse instrument is slightly braked by a brass spring, in order to produce a uniform tension on the paper ribbon, and

thereby a uniform rotation in the coherer tube. The arrangement of such a receiving station is shown diagrammatically in Fig. 2.

In the circuit of the coherer tube (F), there are, in addition to the battery (E), the resistance (W_1), and the relay (R). By means of the switch (U), either the calling up bell (L), or the Morse apparatus (M), with their respective resistances (W_2 or W_3), and the battery (B) can be thrown into the local circuit; W_4 is a resistance arranged in shunt to prevent sparking at the relay.

Such a station is called up when the tube is at rest, and the

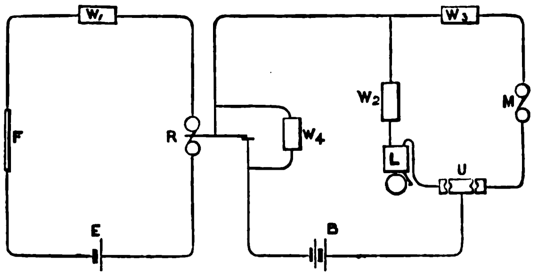


FIG. 2.—ARRANGEMENT OF THE RECEIVING STATION.

bell continues to sound until the Morse instrument is plugged into circuit, and the paper ribbon set in motion.

The diameter of the coherer tube to be employed in this way must not be too small, and the quantity of filings between the silver electrodes must be small enough to roll round the glass wall of the tube. When all the dimensions are properly chosen the dots and dashes stop at the right moment, and the signals are very distinct—certainly much better than with the old arrangement. We are indebted to the "Electrical Review," London, for the above translation and illustrations.

Adjustable X-Ray Tubes.[1]—II.

(Concluded.)

BY A. A. C. SWINTON.

In air at ordinary atmospheric pressure, the nearer the discharge points are together the more easily the spark takes place between them; that is to say, the shorter the distance the spark has to leap, the less is the difference of potential required to make it leap. Curiously enough in high vacua the exact contrary is the case, and the discharge passes with much greater difficulty over a short gap than over a long one. This may be readily

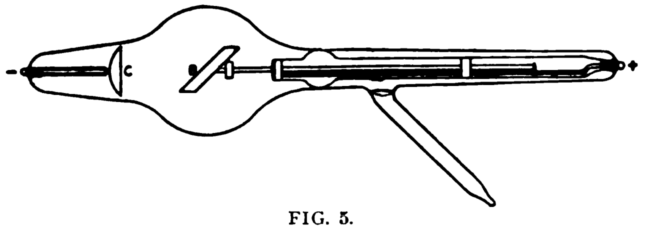

FIG. 5.

seen with an adjustable tube such as I will now show (Fig. 5), and in which I can alter the distance between cathode and anticathode by moving the latter. As will be seen when the distance is very small inside the tube, say only one-quarter of an inch, the spark prefers the alternative gap outside of about four inches, while if the internal gap is increased to about three inches, the discharge then prefers this path, and the exterior gap must now be shortened to about half an inch before the spark will travel that way. It is further found that, in a tube of this description, exhausted to a constant vacuum, the nearer the anticathode is moved up to the cathode and the higher the consequent resistance, the more penetrative are the X-rays; while moving the anticathode in the opposite direction, and thus making the distance greater and the resistance less, makes the X-rays less penetrative. This form of tube was the first adjustable tube designed and made in my laboratory, but this has now been superseded by others which have a greater range of adjustment, and are consequently to be preferred. One disadvantage that it possesses, is that the point of origin of the X-rays is moved for each adjustment. It has also the defect that, if the distance between cathode and the anticathode is made very great, so as to obtain much range, there is a tendency to a

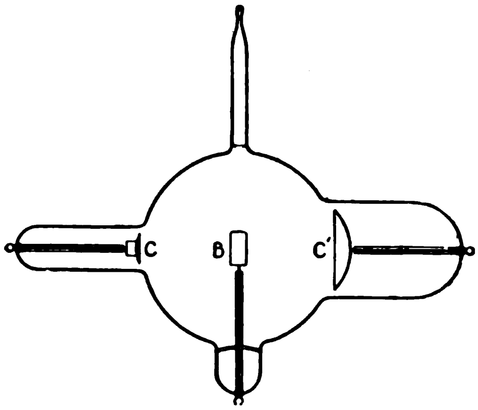

FIG. 6.

want of sharpness, owing to the X-rays being given off, not from a point, but from a considerable area. This, which has been observed in experiment, seems to show that, contrary to what has been stated by others, the cathode rays always do diverge again to some extent after passing the focus, though they do so at a greater and greater distance beyond the focus the higher is the exhaustion.

I have here an adjustable tube made by Messrs. John J. Griffin & Sons, which depends for its action upon the principle that I have just enunciated, namely, that the greater the distance between cathode and anticathode, the less penetrative, and the less the distance the more penetrative are the rays. In this tube, however, the anticathode is fixed, and it is the cathode that is movable, while the adjustment of the cathode is effected by the magnetic means, according to an ingenious suggestion of Dr. Dawson Turner.

The size of the cathode cup itself is also found to have a very

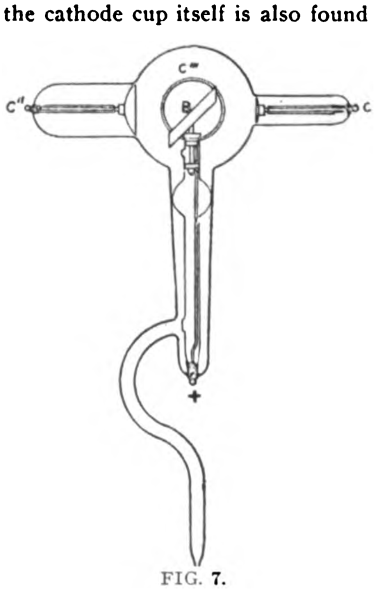

FIG. 7.

great effect upon the penetrative value of the X-rays produced in any given vacuum. I have here a tube (Fig. 6) which is furnished with two cathodes, both of the same curvature (0.75 inch radius), but one of much greater area than the other, the larger being 1.125 inch, and the smaller 0.375 inch diameter. Both cathodes focus upon opposite sides of the same anticathode, which is placed midway between them. All are in the same tube, and consequently in the same vacuum. If I connect the larger cathode, leaving the smaller one for the moment idle, you will

[1] A paper read before the Röntgen Society, London.

see that the X-rays produced are of a very poor penetrative quality, the result giving the appearance of too low an exhaustion. I now disconnect the larger cathode, and connect the small one. I now have an abundance of highly penetrative rays. I may further point out that the resistance of the tube as measured by the length of the alternative spark in air, is much less when the large cathode is in operation than when using the small cathode. Further, if this tube is more highly exhausted, so as to give rays of good penetration with the large cathode, the resistance with the small cathode is so high that the discharge will hardly pass at all.

I have here another tube shown in elevation and plan in Figs.

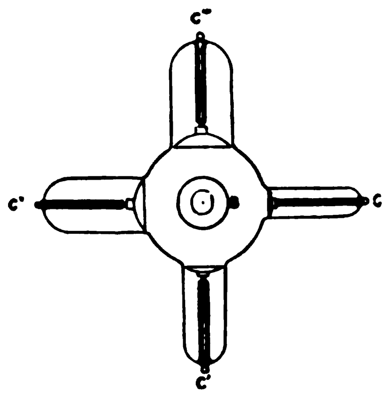

FIG. 8.

7 and 8, fitted with four cathodes of 0.5 inch, 0.75 inch, 1 inch, and 1.125 inch diameter respectively. They all have the same radius of curvature, i. e., 0.75 inch, and all focus upon the same point on the anticathode, which is mounted upon a spindle, so that it can be turned round so as to face any one of them. With this tube, as with the last shown, it is found that the larger the cathode the less penetrative, and the smaller the cathode the more penetrative are the rays produced. There appears to be no advantage in employing extra large cathodes, even when the exhaustion is made to suit them. Experiments with various sizes, from 2.5 inches diameter down to 0.125 inch diameter, go to show that even with the full power of a 10-inch induction coil with mercury break, there is no advantage in making the cathodes more than 1.125 inch diameter. For use with a 10-inch coil they should not be smaller than about 0.375 inch diameter, as, if less than this, they are apt to become overheated, and their surface and form destroyed. For use with 6-inch and smaller coils, very small cathodes, even down to 0.125 inch diameter, will work very well, and will not require such high exhaustion as larger ones. Small cathodes should, in proportion, have a less focal length than large ones for the best results. Probably, a good average size for ordinary work is about 1.125 inch diameter, and 0.75 inch radius of curvature. It is important for the best work that the surface should be well polished, and to be of quite even curvature.

Another simple and, in my opinion, altogether superior form of adjustable tube, which has the advantage of a fixed point of origin for the X-rays, and which has a great range of adjustment, depends for its action upon the fact that the resistance of the tube and the penetrative value of the X-rays that it generates can be greatly varied by altering the radius of the annular space

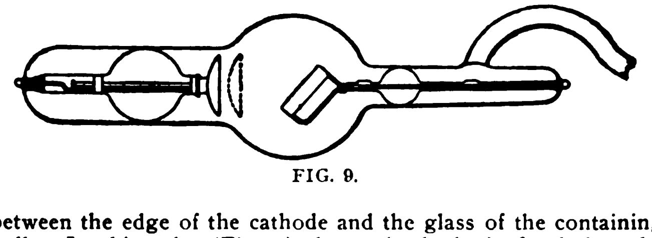

FIG. 9.

between the edge of the cathode and the glass of the containing bulb. In this tube (Fig. 9) the anticathode is fixed, but the cathode is mounted upon a steel rod, held in guides, so that by gently tapping the tube the cathode can be moved to a small extent—say, about one-half of an inch—in and out of an annex, blown on one side of the glass bulb. The shape of the walls of this annex are such that when the cathode is at one end of its travel, and as far as it can get from the anticathode, the edge of the cathode is very near the glass all round; while as the cathode is moved nearer to the anticathode the annular space between the cathode edge and the glass becomes larger and larger, until at the other end of the travel the cathode emerges from the annex into the bulb itself. With a tube of this construction, the greater or less proximity of the glass to the cathode is found to have a much larger effect in increasing or decreasing the resistance of the tube and the penetrative value of the X-rays than the contrary result that would be occasioned by the alteration in the distance between cathode and anticathode. A travel of one-half of an inch is sufficient to alter the X-rays from the highest to the lowest penetrative value, and between the limits of travel any desired degree of penetrative value is immediately obtained. The adjustable tube just shown was made in my laboratory, but here are two others on the same principle, made respectively by Messrs. W. Watson & Sons and Mr. Cossor, who have kindly lent them to me for exhibition.

In conclusion, I should like to lay stress upon the great importance of good and accurate workmanship in the making of X-ray tubes if the best results are to be obtained. In no instrument is work of the cheap and nasty description more to be deprecated. Bulbs should be of uniform thickness, and as thin as will bear the atmospheric pressure. Cathode and anticathode should be placed axially so as to produce accurate focussing, and so that they are symmetrical with the glass. The platinum leading-in wires should not be too small, or by becoming overheated they may crack the glass. The cathode and anticathode should be substantially supported so that they cannot become displaced. The cathode should not merely be roughly stamped out of sheet metal, but should be turned up and polished on a lathe to a true spherical surface. The terminals should be substantial and a long distance apart so as to preclude sparking between them.

As the application of considerable electrical power is found in practice to give the best results, the anticathode should be of sufficient mass not to readily become overheated or deformed. The exhaustion should be most carefully carried out, till as far as possible a permanent degree of vacuum is obtained. Even if tubes made in this way cost more than others, they will give much superior results. They will also prove much more durable, and will in many cases stand being re-exhausted many times. Finally, if eventually the glass is cracked or broken, or becomes too much blackened, the cathode and anticathode will serve again to make another tube.

I trust that I have not wearied you with too much detail, but it is upon detail chiefly that success depends—at any rate, so far as X-ray tubes are concerned—and, after all, of all the apparatus that the practical user of the Röntgen rays employs, the tube is the most important, and perhaps I may say also, the least generally understood.

I must mention, in conclusion, how much I am indebted to the untiring assistance of Mr. J. C. M. Stanton and Mr. H. Tyson Wolff, who have made and exhausted all my experimental tubes, and without whose willing aid I do not suppose I should ever have attacked these very difficult problems.

Electrical Men in the Volunteer Army.

Besides the large number of electricians enrolled in the Engineer Corps of the Volunteer Army, we are glad to note not a few electricians in camp forming part of the militia regiments that volunteered in a body. At Camp Townsend, Peekskill-on-the-Hudson, we find the genial Mr. Robert Edwards, Jr., of the firm of Edwards & Co., Captain of Company B, 8th Regiment. In the same regiment, acting as Corporal, is Mr. M. A. Gilmour, of the Western Electric Co.; also Mr. Shearer, of the Western Electric Co. Mr. E. W. Rockefellow, of the Western Electric Co., is First Lieutenant of Company B, 47th Regiment. Mr. J. M. Larvens, purchasing agent of the New York Electric Equipment Co., is 2d Lieutenant of Company B, 47th Regiment.

MR. WALTER A. CROWDUS, electrical and mechanical engineer of the American Electric Vehicle Co., of Chicago, has resigned his position to devote his time to European negotiations for his electric storage battery. He will pay the Electrical Exhibition a visit en route for London.

It is not expected that the work on the extension of the third-rail system of the N. Y., N. H. & H. R. R. to Bristol will be finished before July 1, so that cars can be run. The line from New Britain to Plainville is finished.

[Entered as second-class matter at the New York Post Office, April 9, 1888.]

Vol. XXV. NEW YORK, MAY 19, 1898. No. 524.

Died For Their Country.

EVERY electrician will grieve at the news of the death of the two Edison Co.'s electricians, who, while working down the Bay, laying torpedoes off Sandy Hook from a small boat, were run down by the French liner "La Touraine" and drowned. The men were Robert Middleton, married, and Victor Posso, single. Thus the war has claimed its first victims in the vicinity of New York, and from the electrical ranks. The incident, sad as it is, is but one more proof of the active part that electricity is playing in this war, and of the readiness of electrical men to stand up and be counted in. It is, indeed, a pity that more of them are not with our fleets, for it is evident that in cable laying, cutting and repairing they could do useful work.

As to the present incident, we can only trust that the men do not leave behind them relatives without support. The generosity of the Edison Co. is well known, and if other aid is needed, we pledge The Engineer to do its share in securing relief for the families of those who have thus died for our protection, at the post of duty. Those families should certainly be entitled to pensions.

"Features" at the Electrical Exhibition.

THE many-sided nature of electricity is admirably brought out at such an exhibition as that now being held in Madison Square Garden. It is said to have been one of the desires or ambitions of the management not to repeat any one "big" feature of the show of 1896, while presenting many things not then included; and they have been highly successful. Of course not everything has come out on the same plane of brilliancy and smoothness of result. That would have been too much to expect, for where a great deal is attempted a margin of disappointment is inevitable. But it is only fair to say that nearly every item of novelty has shown distinct merits as an attraction, and that in instructive variety the Exhibition of 1898 is vastly superior to that of 1896, which set a pace very hard to beat.

In reality, it is worth while to study the attitude of the public as exemplified on these occasions. Does it merely want to be shocked and startled, or does it come for solid instruction and rational entertainment? The latter is surely the case. That a large proportion of the visitors should go away, after all, without any clear idea of what it is all about, is only natural, but it is impressive to note how thickly the crowd gathers the moment any exhibitor gives a lucid explanation of what his apparatus will do, and how it is done. The beautiful Schoonmaker exhibit of the "field of force" appeals very strongly, for example, even to medium intelligences, and once the notion of the way magnetism acts is implanted, the other steps of comprehension are found easy; while the next door exhibit of the Edison ore separation drives the lesson home in a practical way. By slow degrees, knowledge of a special kind permeates the mass of the community, but the process is inconceivably quickened by such a brilliant, varied and instructive exhibition as that at Madison Square Garden. It is popular education on the largest kind of scale, and it would certainly be impossible to render instruction more palatable and attractive.

The Compound Winding Patent Void.

ANOTHER "controlling" patent has been declared void and in such unmistakable manner that there can be no possible hope for its rehabilitation by a higher court. This time it is the Edison "compound winding" patent which the General Electric Co. has so long held as a club over the heads of its competitors. In deciding against the validity of the patent Judge Coxe, as it were, affirmed the decision rendered on the same patent in the English courts where, after fierce litigation, the bill of the plaintiff was dismissed. In both these celebrated cases the Brush "teaser" patent was held to be a plain anticipation. The attempt to hold the Edison claim for the combination of a compound wound dynamo with lamps connected in parallel, was likewise rejected, and with incontrovertible arguments. We are not informed as to whether the General Electric Co. intend to appeal the case to a higher court, but we can not but contemplate with sadness the large expenditures which the trial of this case involved both to plaintiff and defendant, especially in view of the fate of the patent abroad. Thus, one after another many so-called controlling patents of the General Electric Co. have been reduced to a mere shadow of their former number and potentiality. Now that most of them are no longer available as fighting material in the war of commerce, we may look for a more natural and healthy tone in the trade, with the judgment of intending purchasers untrammeled by suits for infringement looming up before them.

Inductor Alternators.

THE electrical arts have fortunately not reached a stage where improvements are slow and designers are completely satisfied with existing types of apparatus. On the contrary, the progressive spirit is as keen as ever, resulting in a constant improvement along the lines of durability and efficiency. In the department of alternating current machinery the lapse of time with its accumulated experience had some time ago shown the weak points of the early designs of generators. The constantly increasing voltages adopted have still further accentuated these defects. While, of course, theoretically there are no limitations to the insulation thickness to withstand any desired potential yet practical considerations soon mark the line beyond which the separation between copper and copper and copper and iron commercially become prohibitive. The history of the transformer early proved the superior resistance to breakdown which a stationary coil of given insulation possessed over a moving one of like construction. This led to the design of alternators in which the magnet system with its coils is revolved and the armature system is kept stationary. Several excellent machines have been designed on this principle. But the trend towards

absolute suppression of movement for all the coils of alternators is strongly shown in the increasing popularity of the inductor machine. This type is by no means a new comer in the field, but it has taken a long time to bring its full merits to the front. The reason for this must be plain, for, besides the, no doubt, important question of insulation it presents electrical and mechanical advantages of no small degree. Though the inductor machine found its first advocates abroad, its prophets found no honor in their own country and it has remained for America to demonstrate fully the true value of this machine to which the improved methods of construction employed have contributed not a little. Already a number of our manufacturers have adopted such designs as standard, while others, we understand, are preparing plans for bringing out such machines. It is not likely that the inductor machine will entirely displace the types of machines now in vogue, but there is little question that it appeals strongly to the instincts of the central station man and the private plant owner and that, other things being equal, it will always command something more than respectful consideration.

The N. E. L. A. Chicago Convention.

THE approaching meeting of the National Electric Light Association at Chicago promises to be one of the best attended of the many successful gatherings of that body. The central location of the meeting at the Western metropolis will of itself attract many who have for several years been forced to forego attendance. But aside from this the programme of papers, topical discussions and entertainment arranged for by President Insull and his fellow officers, will serve to bring to Chicago many to whom the Association's meetings have become a distinct boon. Moreover the intercourse with others engaged in the same industry, the exchange of ideas and experiences have a value which has more than once been expressed on the floor of the Association. Then again, the always welcome salesman, with the latest improvements in apparatus will, as heretofore, serve to bring the central station operator up-to-date.

MUNICIPAL AFFAIRS

Municipal Electric Lighting.

BY "ELECTRIC."

I have read with interest the articles under above caption, written by Mr. Bowker, on the one hand as against the municipal ownership of electric light plants and the reply of Professor Commons. I wish to call attention to one phase of this question, and one to which Professor Commons, to my surprise, in his first article in The Engineer of February 24, seems to lend his countenance, viz., where he writes: "I agree that Government, whether national or local, cannot safely undertake experiments on a large scale. But in the sense in which I use the word, the introduction of new modes of manufacture or service and the creation of new wants among the people are matters involving risks of an incalculable and speculative kind, and this is not the business of the Government. Private parties should be encouraged to push forward in all the untried fields."

This will apply to parties who in the early days of electric lighting had enough enterprise and push to invest their money, but who, according to Professor Commons, must now be supplanted by the municipality, and those also who have ventured in localities where for years the investment was not profitable, but as soon as the same does show signs of self-sustaining abilities then should the municipality step in and occupy the field.

I have no disposition to argue the question as to its bearing of cost. I do not think that is the pinch of the case, so far as electric lighting companies are concerned. It is a question whether their property shall be confiscated or not, and a protection from this possibility should be endeavored to be had in all our States. This could be done in about the same manner that is now pursued in condemning private property for public use. As it is now, the municipality can, when authorized to go into the business, render the plant in the community worthless by buying a new outfit, when the one already installed would serve their uses just as well. It may be said that the municipality would prefer buying the installed plant, but my observation has been that they always expect to instal a new plant. Oftentimes the agitation is the result of selfishness or jealousy, or both combined.

Where there is no private corporation doing electric lighting it is entirely a local question whether it should be done by the community or private enterprise, but once the choice has been made and franchise given and a plant installed by private corporation, then it should receive protection under the laws guaranteeing it from what becomes virtual confiscation, viz., municipal ownership in its territory.

This is not a question of cost, but a question of simple honesty, and one which our electric light people and journals ought to be forcing and agitating until we are protected from this threatening danger which continually hangs over our interests.

LITERATURE

DER ELEKTRISCHE LICHTBOGEN (The Electric Arc). By Prof. Dr. Ernst Voit, Stuttgart, 1896. Ferdinand Enke. 74 pp., 6½x10 inches. Paper. Price, 50 cents.

This pamphlet is the first of a series of lectures on electrotechnical subjects, issued under the supervision of Dr. Voit. In this one the author has attempted to gather all reliable data on the electric arc and present them in connected form, giving the most trustworthy results the greatest prominence. Like all German works of its class, this little book evinces extremely painstaking and laborious research, beginning with the discovery of arc phenomena by Volta in 1800, and including the vast amount of work done since then up to the present.

The first few pages deal with the historical development of the electric arc, and contain a general description of its outward characteristics, and of the most usual varieties of carbons employed, after which the author plunges into those intricate phenomena which have made the arc one of the most investigated, but least understood, phenomena of electrical science. By means of curves, which show the relations of the variable quantities in the arc with reference to each one of them in turn, Dr. Voit has presented in striking and comprehensible form, facts which lie hidden in countless tables and treatises.

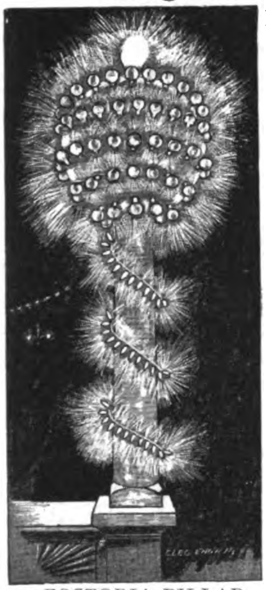
Nevertheless, the results here presented as trustworthy should not be taken as generally applicable. Unfortunately the author does not give all of the conditions under which the experiments were made, such as the amount of resistance or induction in the circuits, the temperature and density of the air, the direction and intensity of air currents, if any, nor the details of the arc lamp and dynamo mechanisms used in the tests. More important still is the failure to describe the means by which current and voltage were varied.

In spite of these omissions, this work must prove of great value to any one interested in the open arc theoretically or practically, owing to the thoroughness of the research and the weeding out of masses of useless or even misleading data. At the time that this treatise was written the enclosed arc was too new and too little understood to obtain recognition, which accounts for Dr. Voit's failure to give it any consideration in what is otherwise a most comprehensive review.

JOSEPH BIJUR.

NEW YORK.—I read The Electrical Engineer each week and consider it a reliable and thoroughly up-to-date journal.—A. B. Rodriguez.

Doings At the Electrical Exhibition.



FOSTORIA PILLAR.

THE past week was a busy one at the Electrical Exhibition, and although the weather was simply outrageous best part of the time, the crowds thickened as soon as there was any promise of a change for the better. The chief events of the week were the lecture by Dr. S. S. Wheeler, the Gramophone Concert with the help of the famous Banda Rossa, and the Telegraph Tournament on Saturday night. The current week opens with a phonograph concert on Monday night by experts from the Edison Laboratory, and that will be followed up by popular lectures and special entertainments of various kinds.

During the week many additions were made to exhibits we have already described. An interesting addition to the exhibit of the New York Telephone Company is a collection of special apparatus for telephone communication under peculiar circumstances. Among this unique collection will be found a complete installation for maintaining communication between the diver at work and those in charge of the air pumps and life lines on which the safety of the diver depends. The diver's helmet contains receiver and transmitter so placed as to be always in position for use. The wires pass through the hose pipe to the telephone set and batteries on the boat. This outfit is shown fitted up for use in a life-size diver's suit. Another telephone set of a form rather unusual to those accustomed to have their telephones fixed on the wall or standing on a desk is mounted in a massive brass standard some four feet high, which to all those who have been at sea at once suggests the fittings of a ship's bridge. This is the marine set used for communicating between the bridge or conning tower and all the multifarious departments contained in one of Uncle Sam's "ironsides." Several United States warships are fitted up with a telephone system of this order. Another warlike telephone set is the "field set," which contains telephone stations, batteries, signaling apparatus and line wire all in one complete outfit. The wire is on a reel to be slung over the shoulder of the scout or orderly, who becomes a moving telephone station keeping up constant speaking communication over the wire as he pays out the terminal in the staff headquarters. A more peaceful application of the ubiquitous telephone is a mining set in which the delicate telephone instruments are enclosed in a substantial waterproof case to protect them from the rough usage and dampness met with in underground works. The special telephone apparatus attracts much attention to the exhibit of the New York Telephone Company, interesting enough in itself as it is a working telephone exchange giving exhibitors in the Garden communication with the rest of the city all day long.

H. B. Coho & Co. added a distinct novelty to their fine exhibit in the shape of a plate glass switchboard, probably the first ever made. It is trimmed with brass, and presents a remarkably neat, trim and cleanly appearance. All the connections are, of course, in full view, and therefore less liable to get out of order from dirt or neglect.

Another fine new exhibit is that of X-ray work by Dr. W. J. Morton, including a full size photograph of a woman made on one film; a "bicycle foot," a curvature of the spine, and a

GENERAL VIEW OF MAIN FLOOR, MADISON SQUARE GARDEN.

woman's body showing the effect of the use of corsets.

War bulletins were set going on a stereopticon screen during the week by Mr. Gould W. Hart, under the direction of Mr. C. Chamberlain, the press agent, who received the news by telephone from such offices as the "Herald," "Times," "World," etc. These were interspersed with war pictures. In addition lantern displays were given from time to time in the Concert Hall. On Friday evening the gramophone concert proved a success, drawing a large audience to hear the music and explanations. During the week the Edison Electric Illuminating Co. established 5 o'clock tea, started a printing press on war bulletins, and introduced an electrically played piano, all of which innovations were highly appreciated, not only by visitors, but by the regular attendants.

Prof. R. B. Owens, electrical commissioner of the Omaha Exposition, was a visitor to the Exhibition last week, and was extremely pleased, characterizing it as finer than the Electricity Building of the World's Fair of 1893. He had several interviews with exhibitors as to transferring their exhibits to Omaha in June.

One of the striking and encouraging features of the exhibition has been the practical success of the exhibitors. An unusually large proportion of the crowds drawn to the Garden is composed of well-to-do people, engineers, architects, artists, etc., who not only inquire critically, but make frequent orders and contracts. Many of the pieces of apparatus have been sold already, and the inquiries afield are innumerable. In addition to this there are a great many visitors from abroad, in spite of the warlike times, and they are on the alert for novelties, specialties and agencies of all kinds.

The Headquarters of the New York Electrical Society.

AT one end of Newspaper Row, in the Arena Circle, the New York Electrical Society has its handsome headquarters, of which a view is here given. The secretary, Mr. George Heli Guy, is in constant attendance, and has the help of Miss Stack as an assistant secretary to answer the innumerable inquiries of members and visitors. Mr. Koch is also present to look after some of the "features." The space has been divided by Mr. Guy into two parts, the smaller of which serves as an office, and contains typewriting machine, etc. The larger space is furnished with chairs, etc., laid with rugs and decorated with palms. Over the booth is the sign of the society, and in front are two very handsome McIntire enclosed arc lights on ornamental standards.

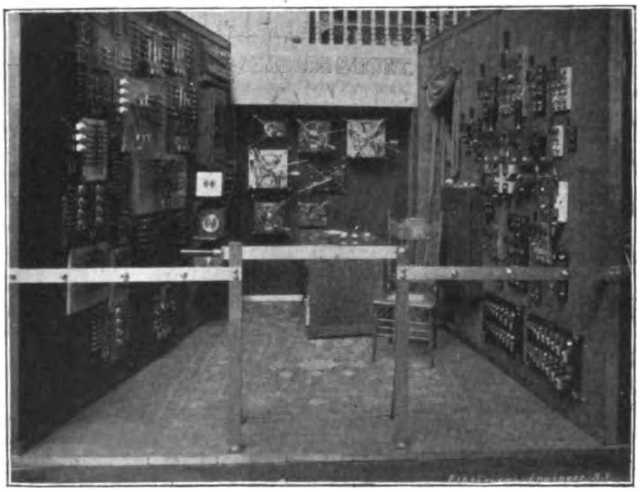
THE NEW YORK ELECTRICAL SOCIETY'S BOOTH.

The back wall has framed groups of the past presidents and present officers of the society, and the message of President McKinley opening the Exhibition. In front of the booth, just within the rail, stands a table holding, under a glass case, the golden key used by Mr. McKinley and previously used also by President Cleveland in opening the Chicago World's Fair in 1893. At the other side of the front rail is an Edison phonograph operated by Chloride accumulator and carrying the wax cylinder on which is the message to the society from Vice-President Hobart.

The society has done excellent work in behalf of this Exhibition held under its auspices, and is reaping already some of the fruits of its work. During the last few months, new enrollments of fifty members at a time have not been infrequent, and last week the secretary submitted a list of 103 proposals for the month! During May a series of lectures is being given in the Concert Hall by the society, the first of which was that by Dr. S. S. Wheeler, noted elsewhere. The society has opened a register at its booth and hopes to have it contain the name of every member before the Exhibition closes.

Exhibit of Zimdars & Hunt.

THE exhibit of Zimdars & Hunt has called forth much favorable comment from visitors to the Exhibition. Situated on the 26th street side not far from the main entrance, it is one of the exhibits first met with by the visitor in his tour, and the



ZIMDARS & HUNT'S EXHIBIT.

glittering array of bright copper objects attract his eye before he has come up to the booth. Upon closer observation these objects are seen to be a display of the panel boards, switches, automatic motor starters, etc., which have given this firm such an enviable reputation. Here will be seen one of the most complete exhibits of panel and feeder boards heretofore attempted, all of the very latest forms, as well as the older and better known types being shown mounted on marble and slates in innumerable variety.

In the rear of the booth all types of the well known Zimdars & Hunt automatic switches and motor starters are shown. These devices are now so well and favorably known that it might be expected that they would have no special interest here for the technical observer, but this is not the case, for there are here to be seen many new types recently brought out, and which contain many new features of merit. A new type of automatic motor starter, known as Type D, is here shown for the first time, and so well has it been received that the firm have already received many orders for them in their various sizes. One wall of the booth is almost entirely taken up with a display of knife switches, lugs, connections, etc. These will well repay a close examination, as the closer they are examined the more clearly will their many valuable features be brought out. All types are shown, and in the various sizes. The copper back connections which this firm has recently introduced also come in for considerable attention here. The instrument switches should be examined by those not already familiar with them. These, though but recently introduced, have so many points of superiority clearly evident that they immediately jumped into the favor of engineers and contractors, and one now looks for them on the latest and most up-to-date switchboards.

In addition to the above there are many other devices of real merit on exhibition here which the visitor will do well to look up.

The booth is enclosed at the front by copper bars representing switchboard bus-bar work, a gigantic knife switch serving for a gate.

The exhibit is in charge of Mr. J. T. Hunt, assisted by Messrs. T. J. Martin and W. S. Atkinson.

The Edison Process of Magnetic Ore Separation.

UNDOUBTEDLY one of the most interesting exhibits on the main floor is that of the Edison process of magnetic ore separation, which is associated in a manner, and very appropriately, with that of Mr. E. T. Schoonmaker to demonstrate the magnetic field of force. But one is led up to the exhibit, made by the Exhibition Company itself under permission from Edison, very gradually. Outside the Garden, on Madison

MR. EDISON'S MODEL IRON-ORE CRUSHING PLANT.

avenue, is a huge block of iron ore rock weighing eight or nine tons. The Garden management objected to its entrance, so there it stands, a telling advertisement of the huge power that Mr. Edison applies out at his Jersey mines, as these blocks are handled by his excavator and crushed by his giant rolls. Over the rock hangs an inscription. Then inside the main approach are two more such playthings also labelled; and then, at the space itself, are two more, not quite so large, but still of such size that half a dozen of them would build a snug church.

The picture herewith shows the tasteful exhibit, which is draped in red. On the walls hang wash drawings of the works at Edison, N. J., loaned by McClure's Magazine, and a photograph of an immense cement foundation made out of Edison sand or sifted crushed rock. On a ledge around the exhibit are placed a series of large glass bottles showing the sand in various meshes, the separated iron, the briquettes, etc. On one of the rocks are placed some trays showing the rock and iron, so that it can be handled, and to illustrate the contrast between the big boulder and the sand it is smashed into, sometimes at the rate of 60 tons in 11 minutes. The exhibit has enjoyed throughout the competent and intelligent attention of the well known electrical engineer, Mr. Francis R. Upton, assisted by a student from the Hebrew Technical Institute, and has been visited by Mr. Mallory, of the works. The central model is driven by a small Paragon motor, and the gearing to handle the sand, etc., so that the process of separation can go on indefinitely, was fitted by the veteran model makers, Wm. Gardam & Son, of this city.

The model shown, built by Mr. Sigmund Bergmann, of the Incandescent Arc Light Company, and loaned by Mr. W. S. Mallory, vice-president of the New Jersey and Pennsylvania Concentrating Works, is intended to illustrate the principle upon which Mr. Edison's process of magnetic ore separation is based. There are deposits scattered through the United States of iron ore which is magnetic. The iron is intermixed with rock, and the difficulty is to separate it cheaply, so that it can be made useful. Mr. Edison has bought up many square miles all over the Union, and is working now on veins in the mountains near Lake Hopatcong, New Jersey, where his property contains 200,000,000 tons of iron rock suitable for crushing. The rock is magnetic in a feldspar gangue, which runs about 25 per cent. of oxide of iron. Mr. Edison's plant will easily handle 4,000 tons of crude ore a day, and human labor has been eliminated from the various processes up to the furthest point. The rock is first slightly loosened by dynamite, then excavated from the face of the vein by huge steam shovels, hauled on skips to the crushers, and then passed through different rollings and crushings. There is one mile of electro-magnets in the plant, and the crushed rock passes before the magnets several times, in the exact manner shown by the model, until it has thoroughly separated from the rock and has become purified or concentrated. The crushed rock or sand falls straight; the particles of iron are deflected or curved inward by the invisible attraction of the magnets, and thus the separation is effected. Every four tons of rock will on the average yield one ton of high grade concentrate and three tons of sand, the percentage of oxide in the final concentrates being from 91 to 93 per cent.

The concentrated iron is next mixed with a "binding" material and then the pastelike preparation is carried to molding machines, where, under pressures running up to thousands of pounds on the whole diameter, it is converted into briquettes, each briquette weighing a little over one pound, and measuring 1¼ inches by 3 inches. These briquettes repel water absolutely. They are dried and hardened by passing slowly on belts through a huge furnace for one hour, subject to a temperature of not less than 600° Fahr. They are then automatically loaded into the cars waiting outside the works to convey them to the blast furnaces of Pennsylvania.

The sand is meantime conveyed automatically outside the plant and dumped. It is highly prized for building (being sharp and crystalline), for track sanding, etc. Other parts of the refuse are also utilized. In fact, everything ground up has a marketable value. The various processes embodied in the plant have been worked out by Mr. Edison in experiments and tests extending over many years, and a great many inventions of his enter into each stage of the work.

Exhibit of the Weston Electrical Instrument Co.

THE Weston Electrica Instrument Co. have arranged a very attractive exhibit which includes the latest models of both their portable and station instruments. Among the latter may be noted the large potential indicator in the centre of the board, the diameter of the scale being 3 feet. Several large ammeters for high current measurements are shown, together with the well known B and F type of station ammeters and voltmeters. The switchboard is also mounted with the large models of the Van Vleck type. These attractive and neatly designed instruments have become famous to the engineering world in many

WESTON ELECTRICAL INSTRUMENT CO.'S EXHIBIT.

installations where questions of economy have been vital considerations. There are also displayed their well known portable types of alternating and direct current apparatus, including ammeters, voltmeters, millivoltmeters, milliammeters, portable galvanometers, ohmmeters, lamp measuring instruments, voltammeters, shunts, multipliers, etc. Among the latest types of direct current instruments is shown an ironclad portable voltmeter. It contains the regular mechanism, but is completely enclosed in an iron case, screening it from all external forces, making it a valuable instrument when used in central station work or

under other magnetic influences. The ohmmeter which is shown is remarkable for its uniform scale, and being similar to the voltmeter in its construction possesses the qualities of that standard instrument. Giving as it does a direct and immediate reading of the resistance in ohms its usefulness is readily appreciated, especially when compared to the work necessary to manipulate a bridge set. It is especially advantageous, when it is desired, to measure like resistances which are to be quickly made as in the lamp industry. Special attention has been given to milliammeters—a special instrument being shown which is used in dental cataphoresis giving readings as low as one-fiftieth of a milliampere. The attractiveness and durability of the portable instruments have been increased by the new royal copper finish. Included in the exhibit is a complete display of the numerous parts of the various mechanisms illustrating the refinements in accuracy of details which characterize the excellent mechanical construction, and which have won for this firm an enviable reputation. This splendid exhibit is in charge of Messrs. Mohr & Koch.

The Exhibit of the Crocker-Wheeler Electric Company.

ONE of the largest, most complete and interesting exhibits on the main floor of the hall is that of the Crocker-Wheeler Electric Company, of Ampere, N. J. In the space occupied by this progressive company are shown motors and dynamos of numerous sizes and types; and the distinction of showing the largest electric generator at the exhibition belongs to this company. It is sold to the New York Central R. R. for the renovated Grand Central Depot, and is a 150 k. w. direct connected type generator, of which the company build seven sizes, namely, the 300, 200, 150, 100, 75, 50 and 30 k. w., varying in speed from 100 to 300 r. p. m. There are also shown 1-12, 1/6, 1/4, 1/2, 1, 2, 3, 5, 7½, 10, 15, 25, 35 and 100 h. p. motors, so well known as to require no further mention here. An 8 h. p. mill type motor is shown which closely resembles a railway motor, being entirely ironclad and intended for use in rolling mills, cranes in mill yards and other dirty, dusty places where it is necessary to protect the moving parts of the motor from particles and from moisture. A 50 k. w. direct connected type dynamo is shown in sizes 1/4, 1 and 5, and motor dynamos, sometimes called double field direct current transformers, are also exhibited. The uses to which they are put are numerous, one of the principal uses being as "boosters" on long electric supply circuits. In addition there are a 7½ h. p. motor with automatic brake; size 22 (14 h. p.), elevator motor, which is distinguished by the fact that it will start under full load with no excess of current above that needed for its operation at full load; sizes ½-100 and 1-100 direct connected type motors. A commutator for a 300 k. w. machine which is a model of workmanship and mechanical construction. A size 1 dynamotor, with automatic circuit opening device and 1-12 h. p. and 1/6 h. p. bracket fan outfits, so well known to the trade, as well as the public. This very complete exhibit, which is in full working order, and is itself a course of instruction in dynamo-electric machinery is superintended by Messrs. Wheeler, Blackall, Doremus, Pedersen, Bates and others.

EXHIBIT OF THE CROCKER-WHEELER ELECTRIC COMPANY AT MADISON SQUARE GARDEN.

The H. B. Coho & Co.'s Exhibit.

H. B. COHO & CO., No. 30 Cortlandt street, New York, with their usual push, have made a very creditable display of the large line of apparatus which they handle. The principal features of their exhibit are the apparatus of the Eddy Electric Mfg. Co., Windsor, Conn., consisting of a full line of dynamos and motors and electroplating apparatus. These include their new six-pole machines for direct connection, their new double voltage plater, and new line shaft motor. There is also a 75 kilowatt Warren alternator working 1,100 and 110 volts off the same machine, driven by an Eddy motor, in actual operation.

The Crown Woven Wire Brush Company, of Salem, Mass., exhibit a full line of motor and dynamo brushes of various types and designs. There is also shown a Van Horne, Berger & Co. gas engine direct connected to a 15 kilowatt Eddy dynamo, which is something new in the market; and from the general appearance and guarantee of close regulation this outfit will surprise some of the gas engine as well as some of the steam engine people. The display of ceiling and column fans of the well-known Crescent type is also a special feature of the exhibit.

The Pennsylvania Electric Co., of Marietta, Pa., are showing a full line of their telephones, and the illuminated sign of H. B. Coho & Co. is composed of translucent fabric, a substitute for glass, which is rapidly being taken up for use in skylights and is manufactured by the Translucent Fabric Co., of Quincy, Mass.

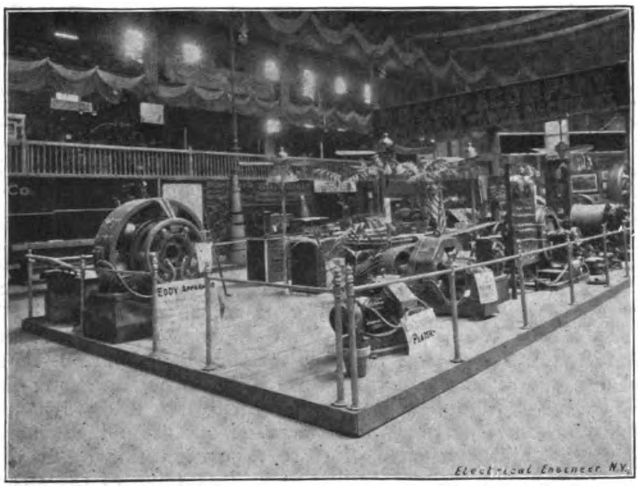
The American Rheostat Co., of Milwaukee, Wis., are exhibiting a 3 h. p. 500 volt automatic starter, and a 20 h. p. 230 volt overload starter. There are also shown a 50 h. p. 125 volt automatic starter connected to an Eddy motor; a 5 h. p. 220 volt perfection rheostat, which is constructed so that it fulfils the duties of a main circuit knife switch, fuse block, starting rheostat with automatic overload and automatic release, and fulfils all the requirements of an automatic double pole circuit breaker. The box is an entire switchboard in itself and is of neat design. Then there are shown a 2 h. p. 230 volt reversible printing press controller, and a 10 h. p. 230 volt reversible elevator controller, provided with an overload safety device, and a 40 kilowatt 125

volt rear of board field rheostat of their own design. They are of fireproof construction throughout and are made to meet the requirements of the trade and the insurance authorities.

The exhibit of Otis Bros. & Co. consists of a complete private elevator outfit of actual size and a working model. It is equipped with the Otis improved push button device, placed in each hall near the elevator shaft. The car is brought to the floor at which the button is pushed, provided all doors leading into the elevator shaft are closed, and no door in the elevator shaft can be opened unless the car is opposite the landing at which it is desired to open the door. Inside the car are placed separate buttons, by pressing which the occupant of the car can bring the car to the desired landing, each button being numbered to correspond to the floor to which it will bring the car, and when the car arrives at such floor it will automatically stop. The buttons in the car are also inoperative if any door in the shaft is open. When the car is moving it is entirely under control of the passenger and cannot be affected by anyone pressing the buttons in the halls. A safety button is also provided in the car, by pressing which the passenger can stop the car at any point. The elevator doors are provided with automatic latches which prevent the opening of any door from the outside unless the car is at that particular landing, and the opening of any door cuts off the current and locks the car so that it cannot be moved until the door is first entirely closed. These safety-guards reduce to a minimum the danger usually incident to the employment of an elevator in a residence, where there is no provision for some one person to be constantly in charge of the elevator.

There is also on exhibition a full line of switchboards, panel boards, etc. The special feature in this exhibit is a glass switchboard with all mountings of copper, it being the first board of this kind ever put before the public, and is only intended as a sample of workmanship and design.

This extensive and interesting exhibit is in charge of Mr. T. W. Kloman.



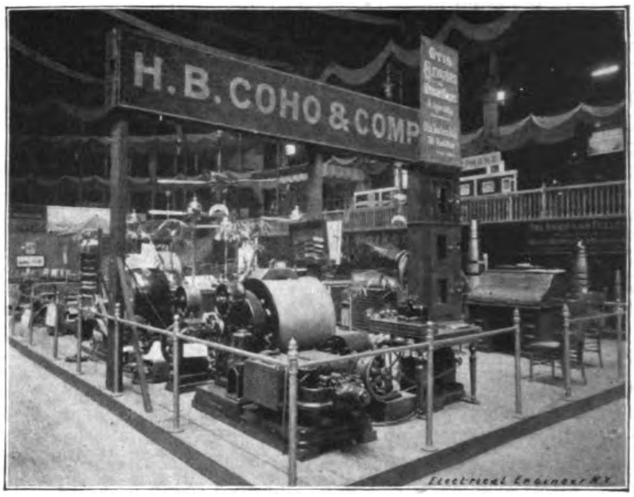


EXHIBIT OF H. B. COHO & CO. AT MADISON SQUARE GARDEN.

The Joint Exhibit of the Fostoria Incandescent Lamp Co., and the Crouse-Tremaine Carbon Co.

THE exhibits of the Fostoria Incandescent Lamp Co. and the Crouse-Tremaine Carbon Co. are located on the balcony just to the right of the main entrance. Together they make one of the most striking displays in the Garden.

On the front line of their space are six columns ranging from 6 to 10 feet in height, surrounded with diagonal lines of miniature lamps of various colors. On the top of each column is a sphere ranging from 13 to 20 inches in diameter, each covered with various shapes and colors of lamps. In all about 400 lamps are used, and the extreme brilliancy of the Fostoria lamp produces a very dazzling and beautiful effect in this novel manner.

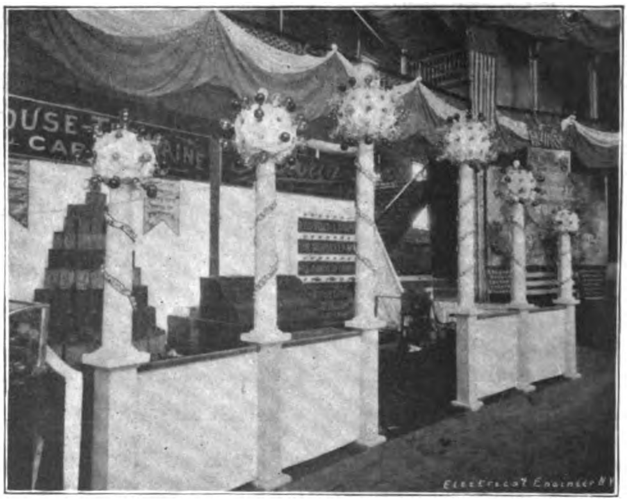
At the rear of the booth is a display rack of five circuits showing the different styles of decorative and standard lamps.

The top circuits show 200 c. p., tubular, candle flame, candelabra, lantern and conical candle lamps. The latter is a new product brought out by the Fostoria Co., and is a very beautiful decorative lamp, adapted for house and lodge hall lighting. The third circuit shows exclusively the Fostoria 220 volt lamp. By a special method of handling the filament their 220 volt lamp is in every way equal to the lower voltage lamps.

These 220 volt lamps are also shown in the conduit of the street car exhibit at the east end of the Garden, in actual service on a varying voltage.

The fourth circuit shows the "Duplex" lamp, patented and owned exclusively by the Fostoria Co. By means of a switch on the base of the "Duplex," the candle power can be doubled at will, or the life of the lamp doubled at normal candle power. This lamp has caused very great interest in the incandescent lamp field during the past year. It is made from 8 to 400 c. p.

The remaining two circuits show various sizes and styles of standard and special fancy lamps, including the pineapple, French etched, L'Empereur, engraved, frosted, street railway, and of all natural colors.



THE CROUSE-TREMAINE CARBON AND FOSTORIA INCANDESCENT LAMP EXHIBIT.

The Fostoria Co. make lamps from 3 c. p. to 400 c. p., one of the most interesting exhibits being a 3 c. p. and 400 c. p. lamp burning side by side. In fact, anything in the shape of an incandescent lamp can be seen here, and a few minutes spent in investigating their staples and novelties is well worth while.

The display of the Crouse-Tremaine Carbon Co., in connection with the lamp display, shows electric light carbons, motor and generator brushes. Several thousand carbons of various styles and sizes are formed in pyramid shape, plain and copper coated alternating.

This company, which for the past three years have supplied the carbons for lighting New York's streets, have devoted themselves to perfecting carbons for arc lighting exclusively, and are now making plain and copper carbons for series arcs, high tension cored carbons for series arcs, cored carbons for constant potential and alternating arcs, and special solid carbons for enclosed arcs.

The display of cored carbons and enclosed arc carbons is very complete. Both exhibits are in charge of Mr. H. Stillson Hart, who has represented the Fostoria Incandescent Lamp Co. and the Crouse-Tremaine Carbon Co. in the East for two years. His New York office is at 726 Broadway.

C & C Electric Co.

VISITORS to the Exhibition will find one of the most interesting exhibits to be that of the C & C Electric Co., of New York. On the main floor, near the electric fountain, they have 500 feet of floor space in which are shown a 40 kilowatt belt type multipolar generator and a 60 kilowatt belt type multipolar generator of the company's latest design, as well as a 60-inch ventilating combination, consisting of a C & C motor of the single field-coil type, directly connected to a 60-inch Blackman fan. This outfit is in operation and an interesting feature of the combination is that four speed changes are secured without the interposition of any resistance in the circuit, through the use of their "Stangland" speed commutating-switch. Four sizes of the well-known C & C bipolar machines are shown, one of them being a dynamo and one being a motor in operation.

Their line of ironclad motors and dynamos both of the open and closed types are attracting a great deal of attention. One of these ironclad motors is fitted with back-gears, mounted upon the field frame designed for a speed reduction of four to one, while another is of the inverted type, designed to go on the ceiling, and is suspended from an iron frame. The company also show in operation an 18 h. p. electric hoist, the motor therein being one of the company's open ironclad type.

A 5 kilowatt marine lighting set consisting of a Case automatic vertical engine directly connected to a C & C entirely closed ironclad dynamo is also displayed. A switchboard of the company's make also forms an attractive feature in the exhibit.

In the basement below the amphitheatre, where the operative plants are shown, may be found a C & C multipolar generator of the six pole type, developing 15 kilowatts at 170 revolutions, directly connected to a 25 h. p. Diesel "rational heat motor." and a switchboard controlling same. In the exhibit of the New York Edison Electric Illuminating Co., a 5 h. p. closed type ironclad motor of this company's make is employed; while the De La Vergne Refrigerating Company drive with one of their Hornsby-Akroyd engines a 2½ kilowatt C & C bipolar dynamo. The company is represented at the exhibition by a number of its staff.

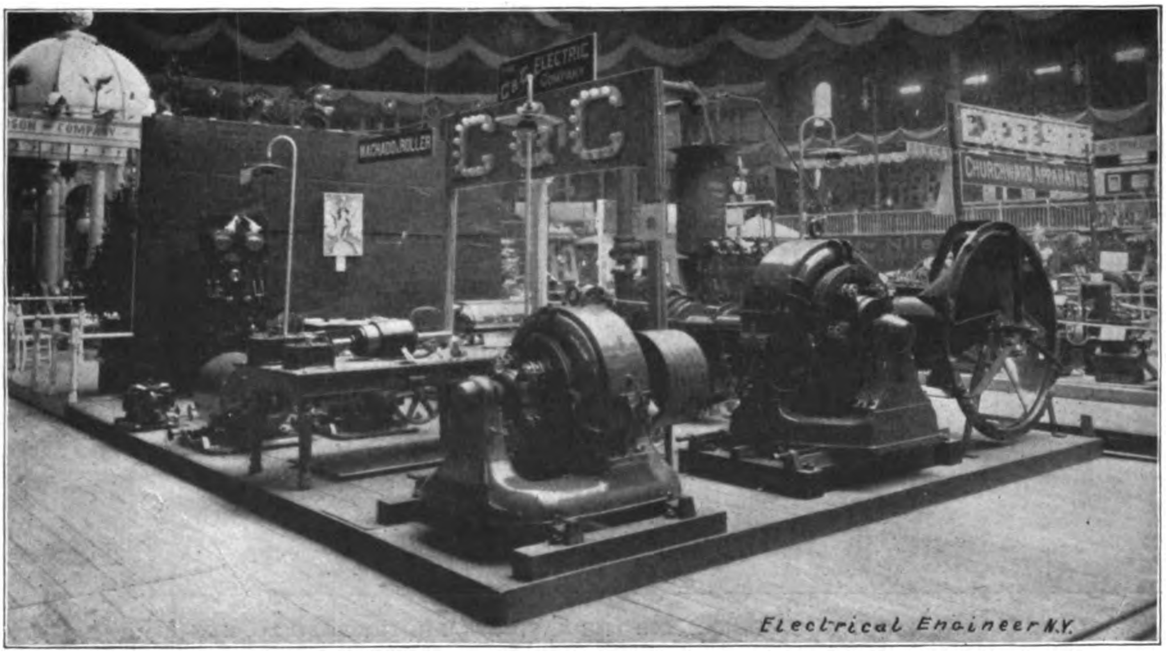


EXHIBIT OF THE C & C ELECTRIC CO. AT MADISON SQUARE GARDEN.

Silex Insulation Co.

ONE of the most tastefully arranged exhibits is that of the Silex Insulation Company, of 39 and 41 Cortlandt street, New York. A number of their smooth-bore, metal-lined, fire and waterproof insulated interior conduit tubes are arranged to represent the pipes of a church organ, and each one is capped by a miniature incandescent lamp. A very pretty experiment

THE SILEX INSULATION CO.'S EXHIBIT.

showing a current carrying heated and sagged wire inside of one of the company's tubes, which would be an impossibility in a tube not metallically lined, is performed by the attendants. This appears to be a practical and permanent elimination of the electric fire hazard. The conduit is waterproof and is made up in various shapes and any desired lengths.

Minerals and metals alone are used in the construction of the conduits. An iron or steel outer tube is separated from an inner tube of metal by finely-pulverized, densely-packed silex. This mineral, in its pure state, is acknowledged to be the most positive dielectric in the art, besides possessing exceptional heat-resisting qualities. Fusing only under the oxyhydrogen flame, it is practically indestructible.

The exhibit is in charge of Mr. F. J. Nash and J. H. Bleoo.

Juvenile Work in Electricity.

THE position that Young America is now taking in the electric and magnetic field is very clearly shown at the Electrical Show now being held at Madison Square Garden, by an exhibit of simple experimental apparatus made by young boys from the Browning School, of this city.

The models shown cover every variety of apparatus that is dear to the heart of a boy, and yet, along the whole line from push-buttons to motors, one is struck by the extreme simplicity of design and the ingenious uses made of old tin tomato cans, cracker boxes, bolts, screws, wire, and the wood that a boy can get from a soap box.

The apparatus in this exhibit was made by boys 13, 14 and 15 years of age, from designs made by Mr. Thomas M. St. John. It clearly shows that good, practical apparatus can be made from cheap materials by an average boy. The whole exhibit is wired and in working order, and it attracts the attention of a large number of parents and boys who hover around to see, in operation, the telegraph instruments, buzzers, shocking coils, current detectors, motors, etc., etc.

Mr. St. John deserves the thanks of every boy who wants to build his own electrical apparatus for amusement or for experimental purposes, as he has made the designs extremely simple, and has kept constantly in mind the fact that the average boy has but a limited supply of pocket money, an equally limited supply of tools, and is usually not overburdened with patience or persistence. He has to be lured along until he becomes genuinely interested.

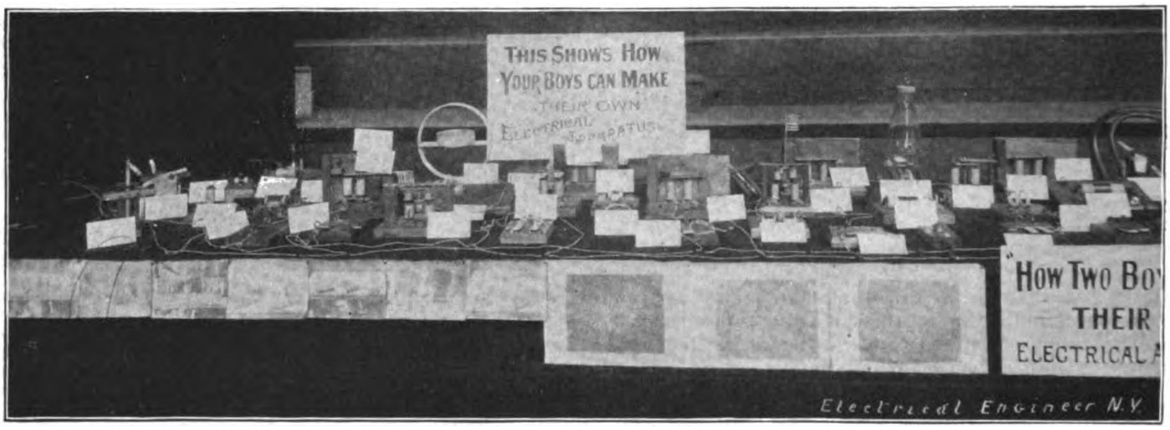

EXHIBIT OF EXPERIMENTAL ELECTRICAL APPARATUS MADE BY THE BOYS OF THE BROWNING SCHOOL, NEW YORK CITY.

Phonographic Exhibit of Edison Mfg. Co.

AS no electrical exhibition would be complete without a personal exhibit of the "Wizard of Menlo Park," or an exhibit of a company manufacturing apparatus under his inventions, there has been arranged on the main floor, to the left of the main entrance, an extensive exhibit of the numerous Edison inventions and their latest modifications. It is a joint exhibit of the Edison Manufacturing Co. and the National Phonograph Co., who are displaying a great variety of electrical apparatus in actual operation. These products alone, without the magnetic influence exercised by the sign bearing the inscription "Thomas A. Edison," attract large and interested crowds every afternoon and evening, not only to listen to the splendid phonographic reproductions, but also to inspect the numerous other novelties of which many deserve special mention. A ball-bearing motor is shown which can be used for almost any purpose where street current is not available. It can be used for fan motor work, sewing machines, jewelers' lathes, dental purposes, etc., and is noiseless, efficient and serviceable. They are all operated by the well-known Edison-Lalande cell. Another instrument which has attracted considerable attention is the cautery transformer, for medical work. This instrument can be applied to either the direct or alternating current and enables the surgeon to do cautery work, diagnostic lamp work, and supplies motive power for dental drills. There is also shown a new apparatus for the use of physicians. They can test urine, blood or sputum in a few minutes by the use of this motoric device, where it used to take hours to do so by the old

THE EDISON MANUFACTURING CO. AND THE NATIONAL PHONOGRAPH CO. EXHIBIT.

method of allowing the liquid to stand until the heavier substance dropped to the bottom of the graduate or whatever receptacle was used. Besides these apparatus the company is exhibiting X-ray tubes and induction coils, Faradic batteries, medical cabinets and appliances, fan motors, and Edison-Lalande cells.

The North American Phonograph Company are showing a new model phonograph which brings the instrument within the reach of anyone desiring it for home or society use. It is called the "standard." With it records can be made and reproduced as distinctly as with the larger and more expensive machines. A great variety of phonographs are shown and the public are entertained at all hours by famous phonographic selections, musical and otherwise. The company have placed a large number of their phonographs in the various booths, where they do useful and highly intelligent work, replacing the much abused exhibition attendant, who is more tiresome or tired and less interesting than this ideal talking machine. A number of concerts have also been arranged by the company and are in charge of the energetic representative of the companies, Mr. E. M. Smiles. The exhibit has also enjoyed the presence of Messrs. Gilmore and Gladstone, of the Edison Mfg. Companies.

Exhibit of the Electrical Engineer.

ONE thing a journal can always do at an exhibition, and that is, distribute copies of itself. At Madison Square Garden this year, however, the Engineer has done this, but has supplemented such work by many features of interest. A general view of the exhibit is shown herewith. It is situated on Newspaper Row, in the Arena Circle, on the main stairs leading to the Concert Hall and Assembly Rooms. The space is dressed with palms, and decorated with draperies, rugs, etc. It contains the usual office paraphernalia for work, and all friends of the journal are made at home. On the desk stands an Edison automatic reversing screw phonograph, driven by Chloride accumulator. The cylinder tells all about the Engineer, and as it goes on and on without attention, it saves breath and bother in

THE ELECTRICAL ENGINEER BOOTH.

a wonderful manner. The space is cooled by two Paragon fan motors, and specially lit by a very ornamental McIntire enclosed arc light. In one corner stands an Empire angle focusing searchlight, of the same type as that used in the brilliant tower illuminations, and made by the Ziegler Electric Co., of Boston. This is flashed in every direction and is intended to represent journalism as the searchlight of publicity. An interesting and beautiful model shown in the space is that of a 10-inch disappearing gun, designed by Mr. E. M. Weaver, electrician of the New York Central Railroad. In these days of war it attracts the greatest attention. There is also a splendid picture of the special electric road for the Pan-American Exposition to be held at Niagara Falls; a plan of the Exhibition power plant; one of the telephones of the Bell exchange and other features. All the staff of the journal is in regular attendance.

The Schoonmaker Exhibit of the Magnetic Field of Force.

WHENEVER a phenomenon presents itself the inquisitive characteristics of human nature seem to assert themselves. To this desire to know why, may be attributed many marvelous achievements. We all recognize that in order to arrive at satisfactory developments we must have some knowledge of the first principles involved, and in order to appreciate and understand the crystallized results of effort in any line, we must interest ourselves to the extent of becoming familiar with that which serves as a basis of operation. Perhaps in no field of science is this more true than in that of electricity, and the great progress made in the last few years serves only to emphasize the fact that great attention has been paid to a peculiar source of energy termed magnetism. Utilitarian demands have given a marked impetus to the bringing about of great results in the electrical field. The electric light has become commercial only since the creation of the dynamo; and we might enumerate many devices which have harnessed this mysterious force for the service of man. We naturally ask what is the source or

EXHIBIT OF E. T. SCHOONMAKER.

fountain head of this power? The explanation to this may be reached in some degree by observing that peculiar force already alluded to, and with which almost every one is familiar, namely the action of the magnet; this remarkable energy is described as the field of force. This field surrounds the pole of a magnet in all directions, but it is invisible, and an ocular demonstration can be rendered only by means of minute particles of iron which arrange themselves in beautiful curves about the poles of a magnet when under its influence. The experiment is performed by placing a sheet of glass or cardboard over a magnet and sprinkling iron filings on its surface. As an answer to the question how this field performs any special function in electrodynamics, we say, and show it to be true, that if a wire closed on itself be moved through these lines of force so as to cut them, we shall see that a current of electricity is at once established in the wire and continues so long as the wire is kept in motion. By increasing these lines we increase the effect. By observation we see that all dynamos are arranged on this principle, as is also the motor. The same thing applies to all electrical apparatus in which the magnet is used.

Such, in brief, is the little lecture given by Mr. E. T. Schoonmaker at his booth on the main floor of the Garden. It is not a commercial exhibit that he has, although he is willing to receive orders for his beautiful magnetic spectra; but is intended to demonstrate clearly the "field of force." On a low draped

platform rests a large sheet of plate glass, about 5 feet by 3, painted white on the under side. Beneath this is a large horse shoe form electro magnet. In the canopy overhead is a sifting box for the iron filings. When this box is gently rocked, the filings drop down softly on the glass, and as the magnet is energized the particles at once range into line around the pole caps and group in the well-known curves. When the plate is tapped, they rush inward to the central rings of filings, and these as the current is briskly thrown on and off, lie down or stand up, "like quills upon the fretful porcupine." Little motors are taken in hand and their fields shown with filings on a sheet of paper. On the tables around the booth, Mr. Schoonmaker has some of his spectra, of matchless beauty, notably those in which by the superimposition of successive plates of glass with the filings he shows the lines literally swinging out through space, or "floating." It is almost needless to add that there is no exhibit more attractive or instructive in the whole exhibition ,and Mr. Schoonmaker is to be heartily congratulated on his success.

A Dozen Exhibits by Elmer P. Morris.

MR. ELMER P. MORRIS, the well-known manufacturers' agent, has arranged in a well-located space on the gallery, the exhibit of goods manufactured by twelve leading concerns. Nearly every branch of applied electricity and the allied industries is represented here, making this one of the most interesting and instructive exhibits at the Show. The Adams-Bagnall Electric Company's display, described elsewhere, is located in this space.

The Card Electric Co., of Mansfield, O., are showing a 25 h. p. motor of the ironclad type, a 12½ kilowatt dynamo, type E: a 3 h. p. motor, type E; and over and underload automatic switches.

The Simonds Mfg. Co., of Pittsburg, Pa., exhibit 25 steel axle gears for railway motors, and 25 steel pinions.

The Keystone Electric Instrument Co., Philadelphia, are exhibiting a full line of instruments. Among the features is a slate switchboard on which are mounted a type "K" illuminated dial and a pair of type "R" instruments. In addition to the above there are shown one of their potential indicators, an arc light voltmeter and a ground detector for constant potential circuits. An excellent show is made by the company's line of portable

ELMER P. MORRIS' EXHIBIT.

instruments, represented by portable voltmeters for direct current only, and portable voltmeters for use on direct and alternating currents. Besides these, they show a pair of their type "R" instruments in practical operation on a switchboard which is used in connection with a dynamo and motor exhibition.

The Highland Electro Chemical Mfg. Co., of Cornellsville, Pa., show a full line of their well-known soldering pastes.

The Forest City Electric Works are making a display of their protected rail bonds and drop forged commutator bars. Well illustrated books on rail bonding are distributed.

The Garton-Daniels Electric Company, of Keokuk, Ia., show a full line of their lightning arresters, which are claimed to be unequalled for durability, reliability and efficiency. They are made in eleven different styles and types for both direct and alternating currents of any voltage.

The Warren Electric and Specialty Co., of Warren, O., are exhibiting a full line of incandescent lamps of all voltages and for all purposes, including miniatures and 220 volt lamps. They distribute paper flags with the significant inscription: "Remember the 'Maine' thing is a good lamp. 'Dewey' make them? We do."

The Kosmic Oil Filter Co., of Easton, Pa., are exhibiting their Kosmic oil filter, which is used for new as well as waste oil. It is claimed to save fifty per cent. on oil bills.

The Insulating Saddle Staple Co., of Brockton, Mass., are pointing out the advantages of their insulating saddle staple for bell wiring, gas lighting, telephone, fire and burglar alarm, railroad signal and telegraph work. The staples have a fibre lining under the shoulder, and can be driven hard down with a hammer without injury to the insulation.

D. J. Sinclair, of Caledonia, N. Y., exhibits automatic flexible and rigid couplings.

Mr. E. P. Morris' own exhibit consists of electric light and railway material and the Monarch insulating paint. A great deal of valuable literature is distributed at this exhibit, among which should be mentioned the useful lamp and wire chart. Mr. Morris is personally in charge of these numerous exhibits and is assisted by Messrs. C. J. Harrington, H. F. Sauville, and A. Hernandez.

Wood, Shaw & Co.'s and the Partridge Carbon Co.'s Exhibit.

A VERY interesting exhibit is that of Wood, Shaw & Co., of 40 Broad street, New York. These enterprising New York agents are making a very creditable display of the goods manufactured by the numerous firms which they represent. Among these should be specially mentioned the Partridge Carbon Co., Sandusky, Ohio, who are exhibiting motor and dynamo brushes and carbons for enclosed arc lamps. Their carbon brushes are so well known to the trade that no further mention need be made here, save that the variety and styles of brushes exhibited are marvelous, and that they are being used on some of the largest generators at the Exhibition. The company's carbons for enclosed arc lamps, however, are deserving of special note, as they

WOOD, SHAW & CO.'S EXHIBIT.

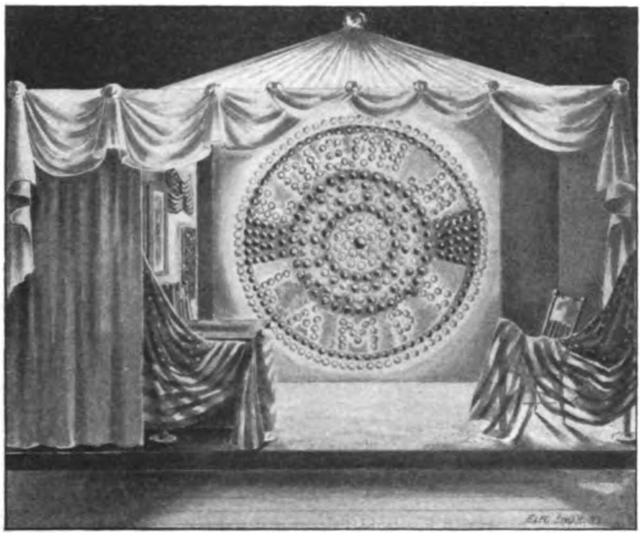
are claimed to be the first American product of this character which is in every way equal to foreign carbons. Mr. J. S. Partridge has produced these carbons, which do not deposit dust and insure a steady, brilliant light, after years of experimenting; and he is to be congratulated on his splendid success. The Nowotny Electric Company and other well known concerns are using these improved Partridge carbons and the steadiness of their lights speaks as well for the carbons employed as for the mechanisms controlling the arc.

Another exhibit in this booth is that of the O. S. Platt Mfg. Co., Bridgeport, Conn., manufacturers of the well known New England switches. These switches are models of mechanical

and electrical workmanship, and are handsome in appearance. An all copper knife switch recently placed on the market is an attraction in itself. The Universal non-arcing lightning arrester is being exhibited also in this space by the Universal Electric Co., 126 Liberty street, New York. These lightning arresters were designed for street railway, line and motor car service, and can stand continual jar and vibration. The cylindrical blocks are fastened to a slate base and placed in an iron box insulated throughout. This lightning arrester is the invention of Mr. H. M. Shaw. The Quaker City Electric Co., Philadelphia, Pa., are also exhibiting here their perfected, moderate speed ironclad type dynamos and motors. Besides the above mentioned firms, Wood, Shaw & Co. represent the Imperial Copper Brush Co., the Acme Copper Works and the Ajax Machine Works. The firm Wood, Shaw & Co. was recently organized to carry on the business of Mr. H. M. Shaw, manufacturer of dynamos and motor brushes and agent for several well known electrical firms. Mr. Wood is a practical electrical and mechanical engineer.

Lamp Exhibit of T. A. Edison, Jr.

PERHAPS the most brilliant, and one of the most handsomely arranged exhibits, is that of T. A. Edison, Jr. It is contained in a handsomely draped booth to the right of the main entrance, and consists of a bank of lamps about 8x10 feet, arranged in circles. Each circle contains a distinct type of incandescent lamp and there are ten of these circles containing an aggregate of about 900 lamps. There are 4, 8, 10, 16, 32, and 50 c. p. lamps, plain, frosted, red, blue, amber, green, and opal, spherical, tubular and the regular pear shape lamps. The con-



T. A. EDISON, JR.'S LAMP EXHIBIT.

nections are so arranged that the various parts of the bank can be lighted separately, and one part of the bank is so arranged that Mr. Edison's name appears in red spherical lamps. There is also exhibited the Edison Junior new 500 volt incandescent lamp, which is probably the only 500 volt incandescent lamp ever made with one continuous filament. The exhibit is in charge of Mr. T. A. Edison, Jr., assisted by Messrs John H. Gill, D. A. MacVean and Charles George.

The Adams-Bagnall Electric Company.

A VERY striking and complete exhibit is that of the Adams-Bagnall Electric Company, of Cleveland, O., arranged by and in charge of Mr. C. W. Phipps, the company's Eastern manager. They are exhibiting a full line of arc lamps manufactured by them, and this is probably the most complete display of arc lamps at the Exhibition. There are shown constant current series differential open arc lamps, 1,200 and 2,000 c. p., for all night service; constant current series enclosed 1,200 and 2,000 c. p.; constant potential series enclosed five in series on 550 volts and two in series on 220 volts; constant potential enclosed and marine arc lamps in single multiple on 110 volts. The standard lamp has a black japan finish and the ornamental

THE ADAMS-BAGNALL ELECTRIC CO.'S EXHIBIT.

styles are finished in royal oxidized copper, yellow brass, 17th century brass and oxidized silver.

The Prindle Pump Co.

The exhibit of the Prindle Pump Company, of 120 Liberty street, New York, is a decidedly unique and up-to-date practical demonstration of the utilization of electricity on direct connected pump work. The type of pump used is that of the Lawrence Machine Company. The general arrangement, as shown, consists of four pumps; the smallest is an automatic house pump with a capacity up to 50 gallons per minute under a suction and discharge lift of 25 feet, efficiency practically 50 per cent. The second pump has a capacity of 250 gallons per minute with 60 to 70 per cent. efficiency, designed for handling hot, cold, dirty and gritty liquids or semi-liquids.

It is erroneously supposed that centrifugal pumps are limited

THE PRINDLE PUMP CO.'S EXHIBIT.

in their economic ability to handle liquids under high heads. To show the fallacy of this idea, the third pump, with a capacity of 1,500 gallons per minute under heads up to 150 feet, is practically operated under an efficiency of 70 per cent. In the fourth pump, capacity 5,000 gallons per minute, a head of 35 feet is carried with an efficiency of 75 per cent.

This latter pump is particularly adapted for circulating, for condensers, water supply, dredging, and sewerage disposal. These pumps are built in capacities of 1 to 100,000 gallons per minute, under heads from 1 to 150 feet with the efficiencies named. They are arranged to connect directly to any standard

motor, for direct or alternating currents. All the pumps are driven by Churchward motors.

The manager, Mr. R. S. Prindle, is in nightly attendance.

Peru Electric Manufacturing Company.

A VERY tastefully arranged exhibit is that of the Peru Electric Manufacturing Co., of Peru, Indiana. They are exhibiting a full line of Peru specialties, such as high potential triple-petticoat, porcelain insulators, Peru style, and Sawyer-Man branches and mains, Edison style blocks, "Peru" multiple tablet boards, transformer fuse blocks, all sizes and styles of insulators, cleats and tubes, and Laclede and Hercules batteries. The exhibit is in charge of Mr. F. H. Schlesinger, the Eastern representative of the company.

PERU ELECTRICAL MFG. CO.'S EXHIBIT.

The Montauk Multiphase Cable Company's Working Exhibit.

AMONG the numerous attractive and very interesting exhibits, and one which is attracting considerable attention, is that of the Montauk Multiphase Cable Company, of New York. This company, whose exhibit is located in Section "S," Space 176-177, have provided a very handsome booth for the display of their remarkably unique thermo-static cables.

The company have several representatives always on duty, and continuous demonstrations are made by them to the numerous interested spectators, who may be seen at all hours about the booth viewing the demonstrations of the adaptability of the cables to all interior uses.

EXHIBIT OF THE MONTAUK MULTIPHASE CABLE COMPANY.

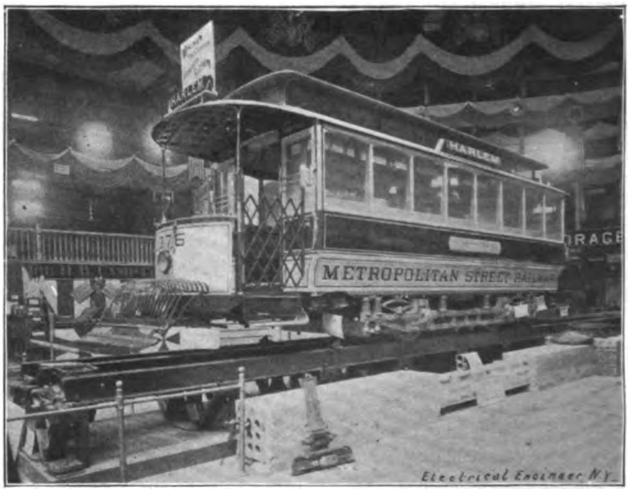
To display their exhibit, the company have provided a very handsome board resembling the side of a room, with windows, etc., upon which are placed various electric instruments, such as telephones, annunciators, call bells, etc. It is in connection with these that the various coils of thermostatic cables are placed, and when the demonstrators burn, cut or heat the cable, the effect is at once seen upon the several instruments, much to the gratification and interest of the spectators. The legitimate abuse by hammering, etc., fails to affect these cables.

The cables are installed scientifically upon the "danger lines" or in the pathway of fire. The necessary information for this is obtained from insurance statistics covering a period of twenty-five years, wherein all buildings are classified, the total number of general causes of fires given, and also percentages or "danger lines" for each particular classification.

The most important fact in connection with the cables is that they are auxiliary to all electric systems. They can be used for all interior electric purposes and obviate the necessity of installing numerous wires for specific purposes, which have no other property than the specific one for which they are installed. This makes all telephone, district service, telegraph, electric light and other wires thermo-static and thus sensitive to heat or flame and quick to give notice of any abnormal condition.

The Company's product was brought to the attention of the public on the 1st of last January, since which time the cables have been specified for various local installations and adopted by the Gamewell Auxiliary Fire Alarm Company, and also for other important channels.

The Company are giving away at their booth various kinds of literature treating upon these cables and their adaptations, diagrams of connections, installation blue prints and information generally for the trade.



STEPHENSON CAR ELECTRICALLY EQUIPPED.

Grand National Morse Telegraph Tournament at the Electrical Exhibition.

IN spite of many drawbacks, not the least of which was the absence of many skilful operators at the front, the telegraph tournament at Madison Square Garden on Saturday last was a great success, as the subjoined record will show. Had not the war intervened, enough competitors were expected to fill two days, but as it was the contest went off with great vim and dash We are indebted to Mr. J. B. Taltavall, of the "Telegraph Age," for much of the data here, his assistance in the affair being one of its most noteworthy and creditable features.

Mr. A. E. Sink, the official timer, performed his part of the programme to the satisfaction of all.

Mr. Fred Catlin, the manager of the tournament, deserves great praise for his untiring energy in the interests of all who took part in the tournament. He was very ably assisted by Mr. Thos. J. Smith, who devoted a great deal of time to the undertaking.

Phonetic records of all the senders in the championship and code classes were successfully made by the Manufacturers' and Inventors' Electric Company, of New York city, through the ingenuity of Mr. T. J. Smith. This is the first time in the

history of the craft that this feat has been accomplished. The official announcement of the results in the championship class, made by Mr. A. E. Sink, was also phonetized, and within three minutes of the closing of the contest was reproduced for the benefit of the audience, amid much appreciative applause. These Morse phonograms are all permanent in their character and can be duplicated at any time and in any number and reproduced upon any of the ordinary forms of the phonograph or graphophone. The duration of tests was five minutes.

Mr. P. J. Tierney, one of the judges, had charge of the phonetic recording, and to his vigilance the profession is indebted for the valuable phonetic records obtained.

Among those present were Thos. A. Edison, who remained during the entire evening session and was an attentive listener, A. S. Brown, J. H. Bunnell, Col. A. B. Chandler, James D. Reid, W. H. Baker, T. R. Taltavall, E. A. Leslie, C. W. Price, F. W. Jones, Wm. Maver, Jr., P. B. Delany, and many others.

THE WINNERS—AFTERNOON SESSION.

Ladies' Class—Sending. Judges: Chas. Shirley, S. F. Austin, Gardner Irving, F. F. Norton, Wm. Maver, Jr., E. W. H. Cogley, A. E. Marr and P. B. Delany. Miss J. McManus, 239 words, 8 errors, Superior Morse, first prize; Miss Emma R. Vanselow, 241 words, 8 errors, Good Morse, second prize.

230-Word Class.—Chas. F. Edney, 233 words, 1 error, Excellent Morse, first prize; F. M. McClintic, 242 words, 5 errors, good Morse, second prize. David C. Grant, who sent 225 words, was commended by the judges for his excellent Morse.

240-Word Class.—J. D. Hinnant, 252 words, 4 errors, good Morse, first prize; F. M. McClintic, 243 words, 5 errors, good Morse, second prize. Mr. David C. Grant was again praised by the judges for his excellent Morse. He transmitted 229½ words.

EVENING SESSION.

Code Class—Sending. Judges: A. E. Marr, P. T. Brady and E. H. Curlette. G. W. Conkling, 345 words, 2 errors, first prize; W. M. Gibson, 330 words, 2 errors, second prize. C. F. Edney, who sent 279 words, was complimented by the judges for his excellent Morse.

Championship Sending.—Judges: A. E. Marr, S. F. Austin, Chas. Shirley, E. W. H. Cogley and P. T. Brady. W. M. Gibson, 254 words, 1 error, perfect Morse, first prize; F. L. Catlin, 253½ words, 1 error, perfect Morse, second prize; J. D. Hinnant, 248 words, 3 errors, excellent Morse; F. M. McClintic, 243¼ words, 4 errors, good Morse; Frank English, 241½ words, 4 errors, good Morse; J. E. Kane, 215 words, 10 errors, good Morse. Mr. J. D. Hinnant received favorable mention by the judges.

Decisions in the fifty message class and the championship receiving class will not be rendered until the judges have carefully examined the work of the numerous contestants.

In the message class the fifty messages were sent by Mr. Frank L. Catlin in 32 min. 37 sec.

SOCIETY & CLUB NOTES

National Electric Light Association.

The following papers have been announced to be read at the meeting of the National Electric Light Association, at Chicago, next month: "Cost of Generation and Distribution of a Unit of Electricity;" by Calvin W. Rice. "General Distribution from Central Stations by Alternating Currents;" by Herbert A. Wagner. "General Distribution from Central Stations by Direct Currents;" by Louis A. Ferguson. "Public Lighting with Relation to Public Ownership or Control;" by Alex. Dow. "Transformer Economy;" by Winder Elwell Goldsborough.

The following "Topics for Discussion" are also announced: "Legislative Policy as to Public Service Corporations;" "Prices and Discounts for Electric Current, and Methods of Charging Customers;" "Standardizing Apparatus for Central Station Use;" "Standardizing Specifications for Incandescent Lamps;" "Freight Rates on Electrical Apparatus." Other papers and discussions will be announced later.

An evening lecture on "Electricity Direct for Coal," with lantern illustrations, will be delivered by Mr. Joseph Wetzler.

Dr S. S. Wheeler's Lecture Before the New York Electrical Society.

ONE of the best electrical lectures of recent years was that delivered by Dr. S. S. Wheeler at the Electrical Exhibition before the New York Electrical Society on "Electrically Driven Machinery," in the big Concert Hall, which, in spite of the bad weather was filled with an appreciative audience. The lecture was illustrated by about 100 slides showing a variety of direct motor applications, and on the stage was a collection of interesting apparatus for experimental demonstration. Dr. Wheeler said:

In being called upon to speak, after an interval of a number of years, upon a subject in which I have always been deeply interested, and of which I have been a strong advocate, it is a great pleasure to find in its remarkable progress that my claims and expectations have been more than realized. It is a common saying, that electricity has made wonderful strides within the last few years, and I think I need have no hesitation in saying that it is in that department of practical electrical work, covered by the subject of this evening, that the greater part of this conspicuous advance has been made. A few years ago, any suggestion of driving machinery by electric power was received with doubt as to its success; to-day electric driving is universally acknowledged to be by far the best method, for a number of reasons, and the developing of this new industry has furnished work to keep the electrical factories busy through the past several years of hard times. The savings in the operating expense of factories have been found to be so great that mill owners have purchased electrical equipments in the hardest times, as a measure of economy.

To what is this great success due. It is evident, from the rapidity with which electric motors have been introduced, that their advantages must be very marked.

First, they are capable of direct-connection to the machinery to be operated, which means that their power, however great it may be and however large the machine, can be transmitted by the shaft instead of requiring a cumbersome belt and a pulley on the driven machine large enough to receive, by the friction of the belt traveling upon it, the needed power. As 1,000 feet of belting one inch wide must pass around a pulley in a minute to transmit one h. p., it is evident that the handling of 100 h. p. will require a large pulley and a heavy belt, which is not only inconvenient and sometimes dangerous, but occupies considerable floor space and requires that the machine be heavy enough in design to support the large pulley and the strain of the belt.

Second, motors are capable of regulation and control of their speed and driving power with great convenience, so that electrically driven machines can be started, stopped, reversed or speeded-up by the use of small instruments known generally as "regulators," which may be placed close to the machine, or in any other convenient location; while machinery driven by belting can be merely started or stopped, and then only with a considerable manual effort in shifting the belt, or can be run at other speeds only by bodily removing the belt to a driving pulley of different size.

Third, motors, when used for driving machinery, are usually attached directly to the machine, and being much less bulky than other means of driving, the entire machine is independent of any line-shafting, and therefore may be located in a convenient position without regard to this limitation, and in many cases can even be picked up and shifted from one place to another, as the exigencies of its work require.

Fourth, electricity permits the saving of ½ to ⅔ the power otherwise required. This results from the fact that when the tool is stopped the motor is stopped and draws no power, whereas, in belt-driving, when the tool is stopped the belt or one of the belts is simply shifted and continues to run on an idle pulley.

And last, electricity presents an enormous advantage in the transmission of power. This subject is so large, and has been so well discussed, that I will not attempt to add anything to it here, but will give one or two experimental illustrations of what I have already stated. (Dr. Wheeler here showed a little portable grindstone.)

Another illustration is in the use of a motor for operating a lathe. A belt-driven lathe must have a line shaft attached to the ceiling, and the ceiling usually has to be strengthened to support this shaft. It must then be carefully made parallel with

this shaft by plumb line and instruments, and then be securely bolted to the floor. A belt of sufficient width to give the necessary friction must be provided, and if the lathe is to be reversed, a second belt, crossed, must be added. The size of the driving pulleys on the shaft on the ceiling must be carefully determined with reference to the pulleys on the lathe, to give the desired speed, and then the lathe may be operated provided the line shaft is kept in motion by a steam engine somewhere. But the lathe cannot be moved.

If the same lathe is provided with an electric motor for driving it, the power may be supplied from any circuit through an ordinary lamp cord, and the lathe may be used in any position. I have here a small engine lathe with a motor built directly on its spindle. The lathe is suspended so as to be swung around in any direction, and will operate continuously while so handled. (Dr. Wheeler then showed the lathe in operation.)

I have one other crude experiment, intended to give an idea of what may be done with an electric drill press, which I will show after describing some views of machinery. The gradual introduction of electric motor driving on machinery has, of course, led to such modifications in the design of machinery as would naturally follow from the differences between belting and motors. I mean, for example, that since the motor is small and can be built into the machine close to the cutting tool or the part which uses the power, that all shafts, gearing, wheels, etc., within the tool, which have been heretofore necessary to receive the driving belt and transmit its power to the tool, may be dispensed with, and then the frame of the machine may be made a different shape, or much lighter, since it does not have these additional parts to support. The attitude of the manufacturers of machinery, during the last five years, who are of course conservative and not stimulated by the interest and confidence in the future of electricity that the electrical men felt, has been interesting. At first they said they supposed their machines could be operated by a motor if the thing would run, and that the purchasers of their machines might try it, but they would take no responsibility. Then they gradually became willing to furnish their machines with brackets and other parts for the ready reception of the driving motor, and now they are anxious to cultivate the electrical trade and to co-operate with its members in bringing out simplified designs of machines with motors incorporated.

I shall have the pleasure now of showing you a number of views of machines combined with motors, some of which are of machines especially modified in their construction in view of the new method of driving. The description of these will be necessarily somewhat disconnected. (Dr. Wheeler here showed the slides, including some of the U. S. Government Printing Office, where the "Maine" report of 300 pages was put through in a night and laid on the desks of the Congressmen in the morning.)

I will now show a crude experiment in further illustration of the extreme portability of electric tools, and at the same time illustrate the method now actually in use in the ship-yards for attaching drills and other tools to the sides of ships. (Dr. Wheeler here showed a drill with magnet which froze or glued to the plate and at once began drilling.)

In conclusion, I can think of no stronger or more flattering evidence of the success of electric power as a new industry than the fact that large quantities of American apparatus are now being installed on American plans and according to American methods in other countries, and there are to my knowledge alone, at the present time in this country, half a dozen engineering representatives of English manufacturers, studying what we have done, and finally leaving orders with us. So that those of us who are not wanted in more aggressive fields of operation at the present time, are at least able to contribute for our country an industrial victory.

New York Electrical Society.

The second lecture of the Society's Exhibition Series will be given in the Concert Hall, Madison Square Garden, on Thursday, May 19, at 8:30 p. m. Professor I. Fujioka, of the Imperial University, Tokyo, Japan, will lecture on "Electricity in Tokyo and the Kingdom of Japan."

A. T. THOMPSON & CO., 26 Bromfield street, Boston, Mass., have prepared a series of stereopticon slides illustrating Cuba and the war.

American Institute of Electrical Engineers.

The 15th annual business meeting of the Institute will be held at 12 West 31st street, New York City, on Tuesday, May 17, 1898, at 8 o'clock p. m. The annual report of Council will be presented, including the financial statements of the treasurer and secretary. The annual election of officers will also be held. Matters pertaining to the business affairs of the Institute will be brought up.

The next meeting, the 15th general meeting, will be held at Omaha, Neb., June, 27-29, 1898.

Colorado Scientific Society.

A very interesting lecture on "Gas and Oil Engines" was delivered by Thos. L. Wilkinson before the Colorado Scientific Society, in Denver, on March 5, 1898. The lecture, which is an exhaustive treatise on the above subject, has been published by the society in the form of a well illustrated pamphlet.

LEGAL NOTES

The Edison Patent for Compound Dynamo Winding Declared Void.—Edison Electric Light Co. vs. E. G. Bernard Co., et al.

Judge Coxe, of the United States Circuit Court for the Northern District of New York has rendered a decision in the suit of Edison Electric Light Company vs. E. G. Bernard Company, et al., upon the Edison patent No. 264,668, for the compound winding of a dynamo, dismissing the complaint.

The Edison patent is declared to be invalidated by the patent to Charles F. Brush, No. 217,677, granted to Mr. Brush for this same improvement some three years prior to Edison's patent. Judge Coxe in his opinion says that the old Brush dynamos of 1878, built in accordance with his specifications, tested during the trial, showed completely satisfactory automatic regulation from no load to full load when running incandescent lamps of low voltage, such as are used at the present day in large cities for telephone exchange signals where they are operated by compound wound dynamos in all essential respects like the Brush compound wound dynamos of 1878-9. In fact, the Brush dynamos of twenty years ago can be put into operation where a modern compound wound dynamo is used, without any modification or change whatever, so that if the Edison patent were sustained, it would involve the enjoining of the use of dynamos built for the same purpose as that set forth in the Edison patent No. 264,668, and built four years before the date of his application.

As to the contention of the plaintiff that the Edison patent referred particularly to the application of the compound wound dynamo for feeding electric lamps, Judge Coxe says:

"To restrict the Brush patent to electroplating would be as unfair as to restrict Edison's to electric lighting. The one illustrates his dynamo in connection with the first named translating devices, and the other with the second named devices. As before stated the patent cannot be limited to any one multiple-arc system of electrical distribution, but if it could be, invention is not involved in changing one series of translating devices for another.

"It seems probable that, if this controversy related to any other machine for generating and regulating power, contention would cease the moment a device was discovered in the prior art as near to the patented machine as Brush is to Edison. The mystery and uncertainty which surrounds everything relating to electricity and the feeling of admiration, almost akin to reverence, for those men who have subdued this unknown and dangerous force and made it do the world's work, makes the Court diffident about applying those principles which are axiomatic in patent law. There is always the apprehension that injustice may be done through failure to comprehend the abstruse and difficult problems presented. This fear has been augmented in the present instance, and the difficulties of understanding the problems involved have been vastly increased by a record into which has been dumped haphazard everything which either party believed had a bearing not only upon the point in issue, but upon the

general subject of electrical distribution. But even were there more doubt as to the correctness of the conclusion reached the Court should still hesitate to enforce a patent in the sixteenth year of its age, and thus lay the entire art under tribute, when the public has had a right to assume that such a system as the defendants are using would not be molested.

"The bill is dismissed."

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued May 10, 1898.

Alarms and Signals:—

ALARM. I. B. Frazee, Blairstown, Iowa, 603,898. Filed March 6, 1897. Employs an electrical circuit adapted to be broken by entrance to the building, whereby electromagnetic mechanism will be released to throw into operation a bell or other alarm.

Batteries, Secondary:—

PRIMARY ELEMENT WITH REGENERABLE NEGATIVE ELECTRODE. O. E. R. Von Burgwall and L. Offenschussel, Vienna, Austria-Hungary, 603,890. Filed Dec. 9, 1896. Consists in first preparing a peroxid plate of porous peroxid of lead on a lead frame, then freeing this plate of air and moisture, then impregnating the peroxid with a water soluble concentrated electrolyte, and then partially drying the electrodes so that they present dry surfaces.

Conductors, Conduits and Insulators:—

CONDUIT WIRING MACHINE. W. E. Cowan, Brooklyn, N. Y., 603,623. Filed Aug. 27, 1897. Consists of a guide-section having runners thereon, a rope-carrier, a rod carrying the guide and carrier respectively, and means whereby the guide and carrier may be forced alternately within a conduit.

CONDUITS FOR RAILROADS. F. S. Pearson, Boston, Mass., 603,656. Filed Sept. 14, 1897. Embodies a trap in the top of the conduit; mechanism by which the trap is opened and closed, and an actuator arranged to be depressed by the car wheel, whereby the trap mechanism is operated.

UNDERGROUND CONDUIT FOR ELECTRIC CONDUCTORS. C. H. Sewall, Chicago, Ill., 603,745. Filed May 8, 1895. Composed of sections of pipes joined end to end and laid in multiple to form a group of ducts.

CABLE STRINGER. F. A. Cannon, Denver, Col., 603,991. Filed Dec. 3, 1897. Comprises means for supporting the cable and suspension wire, a bracket detachably applied to means, a roller journaled in the bracket and adapted to engage the cable during the operation of stringing, and means located adjacent to the roller for supporting the suspension wire.

Dynamos and Motors:—

DYNAMO OR MOTOR. F. Schwedtmann, St. Louis, Mo., 603,709. Filed Oct. 23, 1897. Comprises a casing for the field magnet core cast in one piece, a base formed integral with the casing, a laminated field magnet core inserted in the casing from the bottom and means for rigidly securing the core in the casing.

Electro-Metallurgy:—

APPARATUS FOR EXTRACTING PRECIOUS METALS. J. R. Hebaus, Butte, Mont., 603,904. Filed May 21, 1897. Comprises a tank having an amalgamated copper lining forming a cathode and a multiplicity of agitators each rotating on its own axis and at the same time traveling around the tank, the agitators forming an anode.

Electro-Therapeutics:—

ELECTRO-THERAPEUTIC APPARATUS. G. G. Duke, Chicago, Ill., 603,815. Filed Dec. 6, 1897. Comprises an open-ended casing provided adjacent to its open end with a perforated diaphragm with an inlet-tube opening into the receptacle behind the diaphragm and with an outlet tube leading therefrom between the diaphragm and the outer margin of the casing.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. F. A. Gilbert, Brookline, and E. O. Lundin, Beachmont, Mass., 603,630. Filed July 1, 1897. Enclosed arc lamp having means for holding the carbon in place while removing the inner globe for trimming.

ELECTRIC ARC LAMP. J. H. J. Haines, New York, 603,687. Filed May 27, 1897. Comprises an annular base plate, an outer globe supported thereon, a removable ring for sustaining the globe, an arc inclosing chamber mounted directly upon the plate over an opening therein, and a removable plate closing the opening and carrying the lower carbon holder.

ELECTRIC INCANDESCENT LAMP. W. J. Phelps, Chicago, Ill., 603,705. Filed Sept. 7, 1897. Comprises a vacuum bulb, two sections of incandescent material, one of the sections serving as a resistance to modify the current for the other section.

ELECTRIC LANTERN. F. G. W. J. Adams, London, England, 603,882. Filed April 24, 1897. Details of construction.

SAFETY INCANDESCENT ELECTRIC LAMP. F. G. W. J. Adams, London, England, 603,883. Filed May 10, 1897. A safety lamp consisting of the lamp proper which is provided with a glass chamber inclosing the lamp and joined thereto by the fusion of the glass, and an automatic circuit breaker becoming active upon breakage of the inclosing chamber.

Miscellaneous:—

AUTOMATIC ELECTRIC FEED-WATER REGULATOR. A. E. Maccoun and J. Noey, Braddock, Pa., 603,650. Filed Dec. 3, 1897. Details of construction.

CONTROL APPARATUS FOR ELEVATORS. A. Sundt, New York, 603,665. Filed April 24, 1897. Combines with the motor and working circuit, local circuits operated from the car or floor, and a non-interfering locking device operated by a local circuit and released by the motor.

ELECTRIC CONDENSER. C. S. Bradley, Avon, N. Y., 603,722. Filed July 29, 1897. An electric condenser having as a dielectric, stearate of lead.

ELECTRICAL APPARATUS FOR SCHOOLS. M. E. Crowell, Indianapolis, Ind., 603,875. Filed Nov. 23, 1896. Apparatus for demonstrating the nature and means for generating and utilizing electricity.

ELECTRICAL STEERING APPARATUS. H. O. F. Bindemann, Madrid, Spain, 603,886. Filed June 4, 1897. Details of construction.

Railways and Appliances:—

ELECTRIC RAILWAY. E. C. Crocker, Bridgeport, Conn., 603,624. Filed Sept. 17, 1897. Surface contact system.

ELECTRIC RAILWAY. E. C. Crocker and E. C. Howe, Bridgeport, Conn., 603,625. Filed Sept. 17, 1897. Sectional third-rail system—details of construction.

TROLLEY DEVICE FOR ELECTRIC RAILWAY CARS. L. E. Walkins, Springfield, Mass., 603,672. Filed April 14, 1897. Details of construction.

ELECTRIC HEADLIGHT. F. W. Dressel, New York, 603,876. Filed Oct. 6, 1897. Comprises a flanged ring for securing within a car dash the ring carrying the lamp bracket and lamp; a glass secured within the ring, and the body of the headlight hinged to the fixed ring and arranged to swing inward.

RAIL JOINT. J. Wayland, Newark, N. J., 603,779. Filed Jan. 22, 1898. Comprises a bed-plate and an insulating-shim of substantially the length of the floor of the bed-plate having metal blocks therein at a point between its ends.

Regulation:—

STARTING DEVICE. J. P. Stone, Schenectady, N. Y., and S. E. Doane, Marlborough, Mass., 603,778. Filed Oct. 22, 1897. A starting device for single-phase alternating current motor, comprising two-phase displacing devices in series across the mains, and in shunt to the motor.

Switches, Cut-Outs, Etc.:—

ELECTRICALLY-CONTROLLED SWITCH. E. M. Hewlett, Schenectady, N. Y., 603,786. Filed Jan. 23, 1897. Employed for establishing or interrupting the circuit connections of a system of distribution or electrical apparatus located at a distance from the point of control.

SWITCH FOR ELECTRIC MOTORS. F. E. Herdman, Winnetka, Ill., 603,849. Filed Jan. 9, 1897. Details of construction.

Telephones:—

THROW-OFF SWITCH FOR TELEPHONES. N. Fallak, San Francisco, Cal., 603,681. Filed Aug. 17, 1897. Automatic switch for telephones in interior systems.

THE STOCK MARKET

A Tendency Toward Higher Prices.

There are many reasons for higher prices on the stock market. Among these are the development of Spain's weakness and interior dissensions, the prestige given America by the sweeping victory at Manila, the extraordinarily high prices for our farm products, the large trade balance in our favor, the heavy earnings of various railroad systems, and the general buoyancy of all industries, despite the strain of war. Spanish 4 per cent. bonds have even fallen below 30, while our own 4's are strong around 120, and the premium on gold in Madrid has reached 114. Few people in America wanted the war, but all were determined to stop the atrocities in Cuba, at any cost. Even now it begins to look as though this disinterested resolve brings with it solid rewards, such as the Philippine Islands as our key to the not-too-open door of Eastern trade.

During the week 21,856 shares of Western Union were sold, up to 89¼. Of General Electric, 21,105 shares were sold, up to 36¼. In Boston, American Bell Telephone reached 261. New York Edison was up to 126.

REPORTS OF COMPANIES

General Electric Co.'s Annual Meeting.

At the annual meeting of the stockholders of the General Electric Company, which was held at Schenectady last week, 210,000 shares were represented. The following directors were elected: Gordon Abbott, Boston; Oliver Ames, Boston; C. A. Coffin, New York; T. Jefferson Coolidge, Jr., Boston; C. H. Coster, New York; Thomas A. Edison, Orange, N. J.; George P. Gardner, Boston; Eugene Griffin, Ardsley, Castno; F. S. Hastings, New York; Henry L. Higginson, Boston; J. Pierpont Morgan, New York; Robert Treat Paine, 2d, Boston; and George Foster Peabody, of New York.

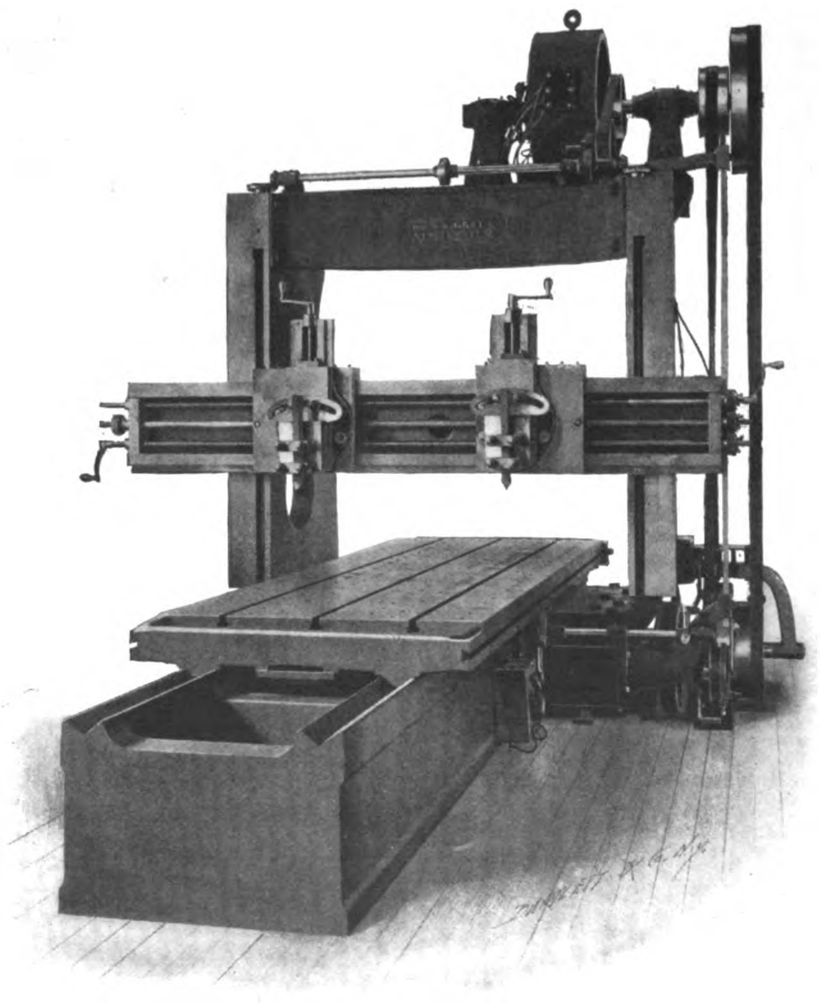
The following resolution was adopted: "Resolved, That the interests of the stockholders require that any proper or necessary adjustment of the impairment of the copital of the company should be promptly made, with a view to the early resumption of dividends."

It seemed to be the general opinion among the directors that the proper adjustment would be to scale the stock by one-half, and such a scheme will be presented to the stockholders for their consideration in the near future.

TRADE NOTES & NOVELTIES

Planer Driven by Bullock Motor.

THE Bullock Electric Mfg. Co. have lately issued a small card which they enclose in all letters to machine builders and factory owners. On one side of the card is displayed the illustration shown herewith of one of their motors operating a 72" Gray planer. The shaft of the motor is coupled direct to the main driving shaft of the planer. The motor is of small size and is placed on top of the tool, allowing a traveling crane to pass over it. The motor is shunt wound to give constant speed under varying loads, and has a capacity of 12 h. p.



PLANER DRIVEN BY BULLOCK MOTOR.

On the other side of the card is a short description of the arrangement of motors on machine tools and the advantages to be derived from this mode of supplying power. The card is printed in two colors and makes a neat enclosure for letters.

THE C & C ELECTRIC CO., 143 Liberty street, New York, report satisfactory sales of their engine type generators.

The "Standard" Acetylene Gas Burner.

One of the greatest obstacles in the way of the introduction of acetylene gas as an illuminant has been the difficulty in obtaining a suitable burner at a reasonable price. Several kinds of burners have been put on the market and some have worked fairly well, but none have given entire satisfaction. However, after years of study and experlment there has been invented a burner which may truly be called the "acme" of success.

This burner is the invention of Col. D. M. Steward, who is well known to the gas trade of the United States as the President of the D. M. Steward Manufacturing Company, of Cincinnati, and later of Chattanooga, Tenn., manufacturers of lava gas tips and gas burners of all descriptions. Col. Steward is also the inventor and patentee of the well-known lava electric insulators which are now in use by some of the largest electrical companies in the world.

Some of the strong points of this burner are: Its capacity—it burns from one-eighth to five or ten feet or upwards per hour. Its entire novelty—it is different in construction and appearance from any other burner on the market. Its strength and durability—it is not a hollow shell, but a solid and substantial piece of lava that needs no care whatever in handling. It is positively non-smoking and non-carbonizing; and finally, it does not infringe anybody's patents. The State Line Talc Co., of Chattanooga, Tenn., who manufacture the burner, are prepared now to handle orders for a limited amount only. Their plant is being rapidly extended, and they will very soon be prepared to meet all demands promptly. A sample will be sent, registered, postage paid, to any point in the United States or Canada upon receipt of 50 cents, P. O. Order.

THE K. McLENNON CO., manufacturers of Gale's Commutator Compound, have moved to 100 Washington street, Chicago, Ill.

Addition to the Carnegie Plant.

The power plant of the Carnegie Steel Company's Edgar-Thomson Mill is to be enlarged by the addition of apparatus from the Westinghouse Electric and Manufacturing Company. The new generator is to be the Westinghouse standard 800 k. w., 250 volt, 85 r. p. m. engine type machine. It will be direct connected to a vertical Allis-Corliss engine, and will operate in multiple with two 400 k. w. Westinghouse generators already installed. The present switchboard is to be enlarged by the addition of a new generator panel, to provide for the operation of the new machinery.

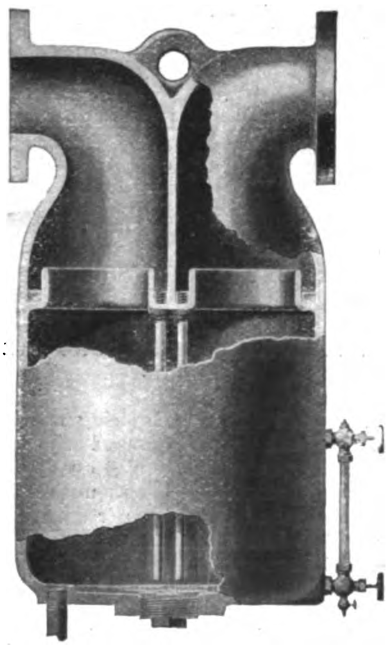
The Hoppes Steam Separators.

The Hoppes Mfg. Co., of Springfield, Ohio, well known as the manufacturers of the Hoppes live steam feed water purifier and exhaust steam feed water heater, have placed upon the market a new separator, having some new points of interest. As shown in the accompanying cuts these separators are made for either vertical or horizontal pipes, but the principle employed in each is essentially the same.

The object of the designer of this separator has been to secure as great efficiency as possible in the separation of the entrained water from the steam with the least possible obstruction to the flow. With this object in view an effort has been to keep the interior of the separator as smooth as possible, and all sharp corners or depending ledges have been avoided, as these not only add friction, but, worst of all, the entrainment would be blown from them by the force of the current sprayed into the steam and add saturation.

As will be seen the steam inlet gradually enlarges into a steam chamber of ten times the area of the pipe, and is then gradually reduced to the original area. No baffle plates or other obstructions are employed, and the steam is not required to take on any centrifugal, zigzag or other tortuous motions in its passages through the separator.

The principal feature of the separator, however, is the interception of the entrainment by gutters which are kept partially filled with water. It has been found that by keeping these gutters or channels thus partially filled all the entrained water or oil is effectually cut off, the channels being arranged to guard both

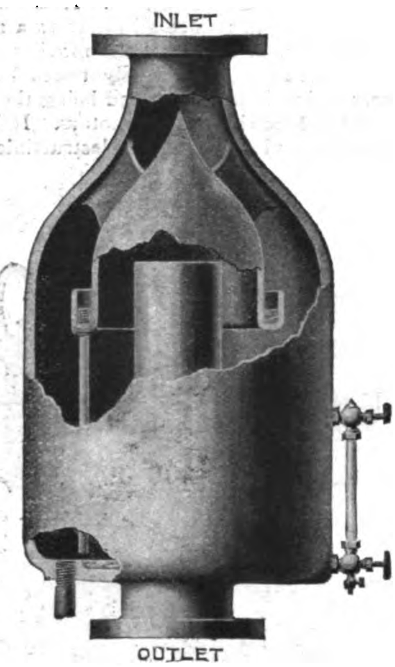


HOPPES STEAM SEPARATOR AND OIL ELIMINATOR—HORIZONTAL TYPE.

the inlet and outlet of the separator. The excess entrainment caught by the gutters is carried to the bottom of the separators by a small pipe or pipes, as shown in the engraving.

In the vertical separator the steam enters at the top, and all the entrainment following the interior surface will pass along the surface to the bottom of the separator and be intercepted by the water at the bottom. The water or oil in the steam which is not following the surface will strike the exterior of the cone in the top and spreading over its surface will be caught by the gutter at the bottom of the cone and be carried to the bottom of the separator by a small pipe provided for that purpose.

In the horizontal separators the steam may enter at either side, both being alike. As the steam enters it passes one of the gutters and as it ascends on the other side it passes the other. All entrainment is caught by the gutters and carried to the bottom of the separator from which it is trapped in the usual manner.



HOPPES STEAM SEPARATOR AND OIL ELIMINATOR—VERTICAL TYPE.

This company also manufactures separators and receivers of large dimensions built on the same plan of the separator. They also manufacture oil eliminators and grease extractors for exhaust steam. All separators for pipes above 8" are made from flange steel, as are also the combined separators and receivers. A new illustrated catalogue of these separators is in press and about ready for distribution.

New Slow Speed G. E. Motors.

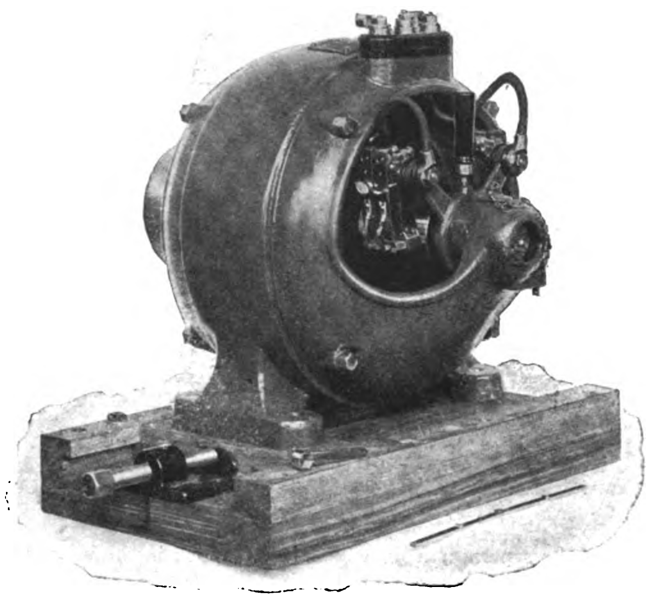
IN redesigning its line of motors to run at slow and moderate speed, the General Electric Company has endeavored to embody in them, such improvements as have been dictated by past experience with, and careful observation of, the operation under actual commercial working conditions, of its preceding types. The result is that the motors of the present type are for their output, perhaps, the lightest and most compact built.

For all powers up to and including 5 h.p. in the slow speed and 8 h. p. in the moderate speed, the motors are bipolar ironclad; up to and including 95 h. p. the four-pole type is standard. The latter method of construction has been adopted on account of its many manifest advantages, viz., shorter magnetic circuits with consequent reduced exciting current; greater output and higher efficiency for given weight and speed; economical distribution of magnetic material and minimum of floor space.

The frames are iron of the highest quality and the poles pieces of special soft steel. The latter being readily removable, the field coils may be taken off and changed without disturbance of either frame or armature and the frame itself being divided horizontally affords easy access to the armature. The pillow blocks of the four-pole machines are cast with the bed plate and the lower part of the machine, thus insuring perfect centering of the armature. The bearings are all self-aligning, self-oiling and of ample size.

The armature core is built up of laminations slotted to receive the coils which, lying below the outer surface of the core, are protected from mechanical strain or abrasion. The spider carrying the core is prolonged at each end in two flanges, upon which the ends of the coils lie without being bent. This is the General Electric cylindrical winding by which a large radiating

surface is given the armature conductors, the length of wire is reduced to a minimum, reducing armature resistance losses and increasing the efficiency of the motor, the coils may be readily removed and replaced, and being imbedded in the slots neither move nor vibrate. The core itself is provided with ventilating ducts through which the air is drawn to circulate throughout and cool the entire armature structure. The low running temperature of these motors is exceptional. It is obtained by so designing all the parts as to reduce all losses to a minimum and giving a free circulation of air to all the moving parts. The coils are made on forms and separately tested before application to the core, the insulation employed being the same as that used in the General Electric railway motors. It is tough, impervious to moisture and practically indestructible, even under



NEW SLOW SPEED G. E. MOTOR.

heavy overloads or by lightning. The commutator segments are of hard drawn copper, supported on a separate spider and the connections between them and the armature coils are carefully made to prevent the possibility of open circuiting.

The brush holders have a solid casting connecting the brush box with the stud and an adjustable pressure spring, giving an even pressure and firm and accurate contact of the carbon brushes upon the commutator—an important factor in securing sparkless and noiseless operation. Change from no load to overload can be made without changing the brushes and without sparking.

The motors ranging from 1 h. p. to 5 h. p. in the slow speeds, and from 1¾ h. p. to 8 h. p. in the moderate speeds, are bipolar, the projecting field effectually protecting the spools and armature from injury. Stability is secured by giving to these machines a centre of gravity very low.

The slow speeds of the four-pole type adapt them especially to all factory, mill and shop requirements. They may be belted directly to ordinary slow speed line shafting without intermediate counter shafting. The bipolar type are adapted to the driving of lathes, printing presses, fans, drills, pumps and, indeed, to almost any power work where small units of power are required and little space available. They are arranged to run in any position, whether suspended from the ceiling, attached to a wall or set upon the floor.

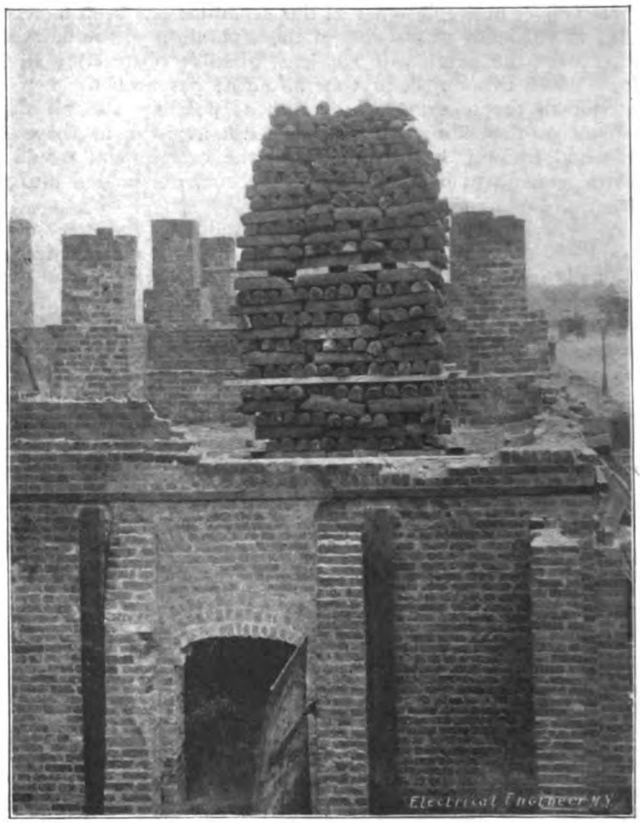
A Warning to the Trade.

The Warren Electric and Specialty Co. inform us that unauthorized parties are offering a lamp to the trade labeled "Warren." The Warren Company suggest the name "Cuckoo" be adopted by the interloping parties, as better adapted to the character of their dealings. The genuine Warren lamps are labeled "The Warren Electric and Specialty Co., Warren, Ohio," and the company issues a caution to purchasers to look out for the label.

Expanded Metal Concrete Fireproof Floors.

SOME very interesting work in fireproofing, specially adapted to power houses and central stations, has recently been done throughout the country by the Manhattan Concrete Company, of No. 156 Fifth avenue, New York. It is perhaps best exemplified in the floor arches built for the plant of the New York Sugar Refining Company. These arches are known as expanded metal concrete floors, and consist of concrete slabs about four inches thick and weighing about forty pounds per square foot, re-enforced along the lower section by a webbing of expanded metal. Due to this metal, the strength of the combined slab is multiplied ten times, while the weight is but very slightly increased.

The New York Building Department made a test of these floors by first placing a distributed load of 150 pounds to the square foot upon them, and then starting a fire under them, which was continued for five hours, the maximum temperature being 2150 degrees Fahr. At the end of this time, a stream from a fire engine was turned on until they were cooled.



TEST OF AN EXPANDED METAL CONCRETE FIREPROOF FLOOR.

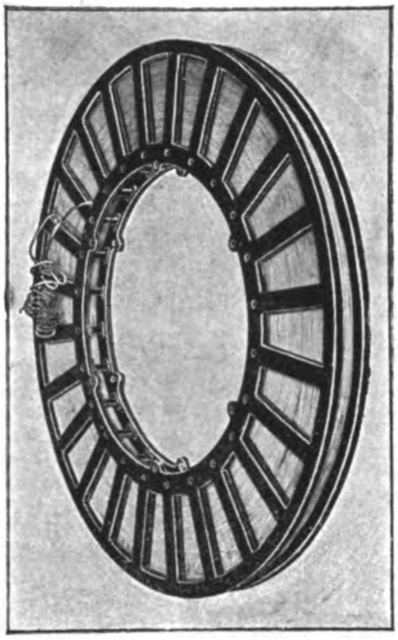
Subsequently a slab of this same flooring was cut through, isolated from the rest, and was then loaded with 32,025 lbs. of pig-iron (Building Department's weighing) on 14 square feet. Further loading was impracticable, but as no break or change occurred under this load of 2,287 lbs. per square foot, it was evident that the arches had not been injured by the fire test described above. The accompanying engraving shows the application of the pig-iron load to the isolated section of floor mentioned above.

Another weight test of expanded metal concrete floors was recently made in the new Stanhope Building at Providence, R. I., and under the direction of Messrs. Carpenter, Stone & Wilson, architects, a total load of 22,349 lbs. was applied on an area of 4'x4'10". The clear span between beams was 5 feet, and although this load was 1,156 lbs. per square foot, there was no resulting deflection.

These expanded metal-concrete arches, with, or without, an artificial stone finish, constitute, on account of their light weight and the small space they occupy, as also because of their fire and waterproof qualities, the ideal construction for electrical power houses and stations.

The New Warren Inductor Alternator.

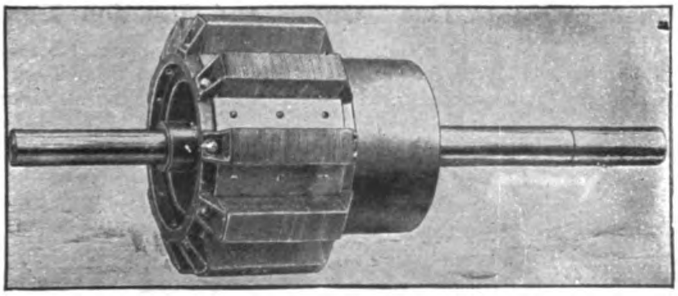
THE inductor type of alternator has come to be recognized as one of special value, and particularly is this true of power transmission where high voltage is necessary and continuous operation essential. Inductor alternators are best adapted to this class of work, due to the fact that the revolving part carries no brushes, commutator or wire, and the only attention the machine requires is the maintenance of a proper lubrication of the bearings. With this latter point provided for, the machine may be kept in uninterrupted service indefinitely.



FIELD COIL WARREN INDUCTOR ALTERNATOR.

Another very important consideration for any class of work is the insulation of the armature coils. This can only be obtained satisfactorily in stationary armatures, because in such there is practically unlimited space available for insulation, and the coil's are not subjected to the mechanical strains accompanying revolving armatures. In inductor armatures the coils are carried on a rigid structure and may be insulated to any required degree. Any pressure above 2,000 volts is extremely hazardous in revolving armatures, while with stationary armatures 10,000 volts is a practical working pressure.

With these salient advantages pointed out, our readers will be interested in the description of the new Warren inductor alternator built by the Warren-Medbery Company, of Sandy Hill, N. J.

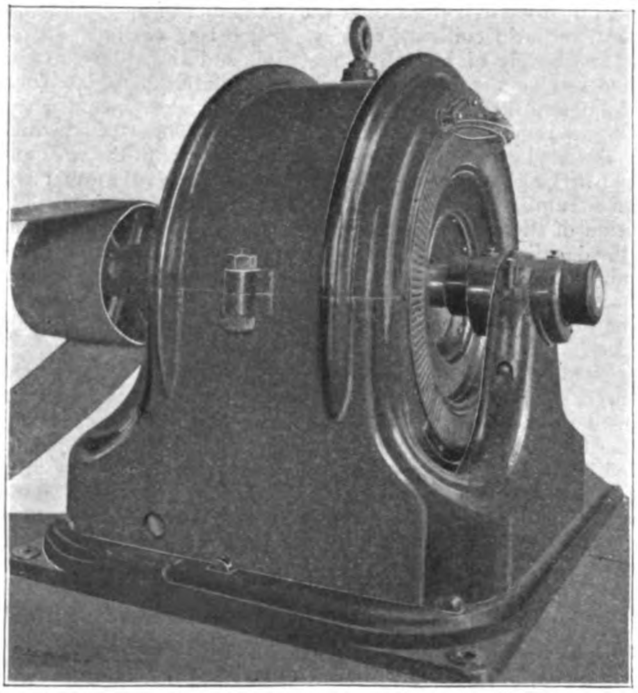


REVOLVING INDUCTOR, WARREN INDUCTOR ALTERNATOR.

As will be seen by the accompanying illustrations, the lower half of the frame of the machine with the base and supports for bearings, constitutes a single casting, insuring great strength and rigidity in the machine, guaranteeing the accurate centering of the revolving inductor while assembling the machine and maintaining perfect alignment while in operation. The bearing sleeves are lined with a high grade of anti-friction metal; the bearing surfaces are unusually large, and the peripheral speed of the shaft in the bearings is moderate. The bearings are self-oiling from an oil reservoir of large capacity, and the distribution of oil throughout the bearings is abundant, being effected by a peculiar arrangement of oil ducts in the interior of the bearing sleeves. The bearing sleeves are made solid, as being the most convenient form for babbitting, in case it should become necessary to re-line the bearings. The supports for the bearings are so designed that when it is desired to remove a bearing sleeve the only operation necessary is the removal of the bearing cap, after which the sleeve may be slipped endwise off the shaft.

The sub-base carries polished steel skids and the machine rests upon these skids with an interposed layer of babbitt, accurately shaped to the configurations of the skids. By means of a powerful ratchet and adjusting screw the belt tension may be easily and quickly regulated.

By the removal of the two frame bolts and opening the armature circuit, on the horizontal central line, the upper half of the frame may be lifted away from the machine. The upper half of the machine carries the upper half of the armature and the corresponding armature coils. The revolving inductor is surrounded at its smaller end by the field coil, which latter is attached to an annular yoke casting. After the upper half of the frame and armature are removed, the revolving inductor, field coil and yoke may be lifted out. By this method of construction, all of the coils of the machine are readily accessible for inspection and repairs.



WARREN INDUCTOR ALTERNATOR.

The armature body is built of a special grade of soft steel, and the method of handling the metal prevents any injuries to its structure, which would increase the losses due to magnetization. For the armature, metal of a very thin gauge is used and the sheets are served on both sides with an insulating compound, which is not affected by heat or age. By this means, the armature eddy currents are thoroughly broken up and practically no loss of power occurs from heating. In addition to this, there are a series of recesses between the cast frame and the outer circumference of the armature, which admit of the free circulation of air entirely around the armature. These recesses are entirely internal and the exterior of the frame casting is retained smooth and symmetrical, without unsightly openings for ventilation purposes. The machine operates remarkble cool, as no part rises over 50 degrees F., even when operated continuously under ten per cent overload.

The armature coils are machine wound and of a plain oblong type, with easy corner bends. This simple form of coil reduces to a minimum the hazards of winding, for neither the armature of the wire nor its covering are subjected to the strains attendant upon the winding of complicated shapes with shape bends, or of coils which are forced into place in the armature. These coils

are thoroughly saturated with an insulating compound, which has no affinity for the copper, but preserves the covering of the wire. For retaining the shape of the coil, a single layer of untreated tape is wrapped all around, and over this a thick coating of waterproofing compound is applied, which makes it practically impossible for moisture or oil to penetrate the insulation of the coil. The insulation of coils is mainly obtained from a special insulation, through which forms the interior lining of the coil slots in the armature. These troughs are semi-flexible, practically non-combustible, do not absorb moisture, are not affected by oil, and do not deteriorate with age. The troughs for 1,000 and 2,000 volt armatures are subjected to a break-down test of 6,000 volts, and the troughs for high voltage armatures are subjected to a minimum of 15,000 volts break-down test. After the troughs and coils are in place in the armature an insulating perforated cover closes up the coil slot and secures the coil and troughs in position. The slot cover is perforated, which allows the revolving inductor to drive a continuous current of air around the coils. This produces such a cooling effect that these machines may be operated continuously, under heavy overloads, without serious heating of coils.

The field coil of the machine is of quite novel construction, for, in effect, it is simply a coil of wire suspended in air; that is, it has the insulation, the radiating surface and the free circulation of air around it, as if it were merely a coil of wire suspended in space in contact only with a number of insulating supports. The field coil case consists of two ring castings, spaced apart with rods of insulating material, and the sides lined at numerous places with narrow strips of insulating material. There is no floor in the case and the sides are cut away, except where backing is required for the insulating strips. The wire is wound over the insulating rods and is in contact only with the rods and strips; it is a skeleton case, which leaves exposed the outer and inner circumferences of the coil, and practically both sides. The rotation of the inductor produces an agitation of air all around the field coil with a constant circulation outside through the openings in the yoke, and the coil will stand severe overloads without injury.

The machines are handsome in design, of fine finish, and incorporate the highest grade of workmanship. The efficiency is remarkably high, being equal in this respect to the best designs of direct current generators, and the inherent regulation is claimed to be by far the best yet attained in alternators of any type. The placing of all the armature coils in a single wreath at one end of the machine and the surrounding of every armature pole with an armature coil, it is claimed, produces better combined efficiency and regulation, and a more correct form of current wave than any other construction. To these features the Warren-Medbury Company has united a robust and workmanlike construction, comprehending simplicity, accuracy and durability, forming a conjunction of desirable features and producing a most practical and reliable machine.

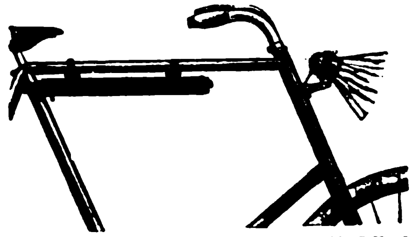
The illustrations are made from photographs of a 150 k. w. machine recently installed in the station of the Ballston Electric Light Company, Ballston Spa, N. Y., by the Warren-Medbery Company. The officers of this company are: H. J. Medbery, president and general manager; H. B. Warren, vice-president and electrical engineer; H. E. Tidmarsh, secretary, and Geo. W. Wait, treasurer. Messrs. Fairchild and Sumner represent the company in New York, with offices at 39 Cortlandt street.

"La Marquette" Electric Bicycle and Carriage Lamps.

The Portable Electric Light Co., of 1242 Marquette Bldg., Chicago, have just brought out a complete line of their "La Marquette" electric bicycle and carriage lamps.

The headlights or reflectors are made entirely of brass, nickel-plated and contain powerful incandescent lamps which are assisted by highly polished reflectors together with imported ground lens. The bicycle reflector can be attached to head or fork of frame as desired. The road wagon lamp reflector, as well as the dashboard lamp, have a neat, secure attachment for the dash. With the improved enamel reflector a perfect focus is obtained, making a clear field of light. The road wagon reflector is four inches in diameter and makes night driving on country roads a pleasure. The dash lamp is put up in very compact form, battery and reflector being encased together in nickel. The hand lamp and watchman's lantern are put up in the same neat form.

The batteries employed are dry cells, and are put up in cartridge form; when exhausted they can be replaced by new cartridges, which can be purchased in all prominent locations,

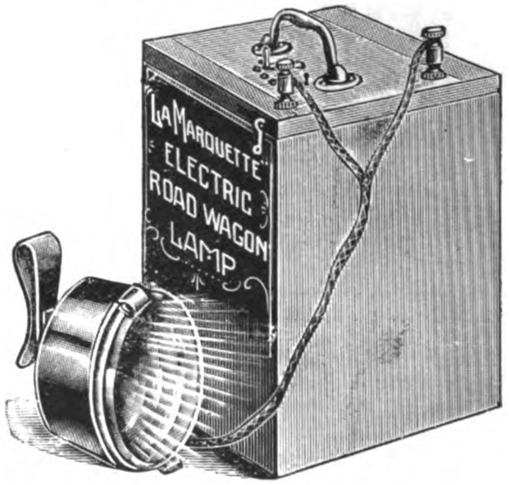


"LA MARQUETTE" ELECTRIC BICYCLE LAMP.

ready for use at a moderate cost, thus avoiding all inconvenience of charging or cleaning.

The bicycle battery is neatly enclosed in a tubular leather case and will fit any make drop or diamond frame on the market. These batteries with a special incandescent lamp will burn fully 15 hours, the last burning hour being of equal brilliancy to the first.

Batteries for dash and hand lamps, as well as the watchman's



"LA MARQUETTE" ELECTRIC ROAD WAGON LAMP.

lantern, are put up in square cartridge form of equal strength with the bicycle batteries. These batteries are enclosed in the same nickel plated case that the reflector is attached to.

The road wagon batteries are encased in handsome hardwood boxes with brass trimmings and show 60 to 75 burning hours with special incandescent lamps.

Chase "Knock Out" Outlet and Junction Box.

L. A. Chase & Co., Inc. 161-163 Fort Hill square, Boston, Mass., have lately placed on the market the Chase "knock-out" outlet and junction box, which has met with general favor

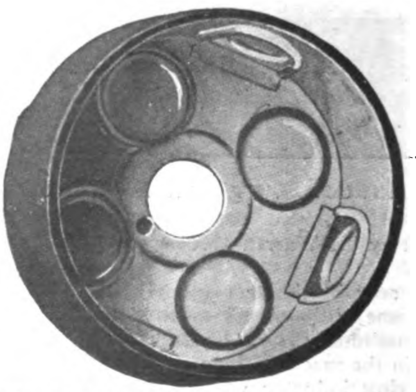


FIG. 1.—CHASE CEILING OUTLET BOX.

among electrical contractors and boards of fire underwriters. This box is made of special grade of iron, and heavily coated

with a hard, black enamel, having the best insulating qualities. The box is so constructed as to have, at frequent intervals on its surface, thin webs or films which a slight blow of a hammer will "knock out," leaving round holes for outlets in as many combinations as are generally required.

The method of attaching the box to the conduit is new, and has many advantages over usual forms now in use. A hollow bushing or nipple, which is threaded on the exterior and smooth and insulated with enamel on the interior, is passed through the hole made in the box at the point desired, and screwed into the coupling on the end of the conduit. This makes a perfect mechanical connection, which can be made watertight. By means of this nipple, wires can be readily pulled through the tube into the box without any danger of abrasion or injury to the insulation of the wires. This will prevent the frequent and troublesome grounding so often met with in outlet boxes. One great objection to boxes in general use is the impossibility of removing them, if broken or injured, without removing considerable other work that has been completed.

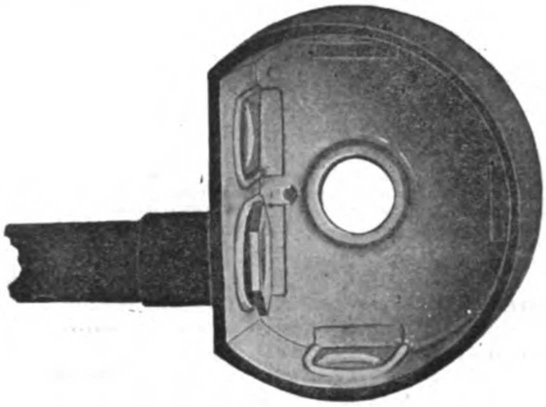

FIG. 2.—CHASE WALL BOX.

FIG. 3.—CHASE NIPPLE.

The Chase box can be instantly disconnected from the conduit by unscrewing the nipples from the inside of the box, thus allowing the box to be withdrawn, regardless of the number of conduits that enter it.

Fig. 1 represents the ceiling outlet box, which may be used for the outlets where the conduits enter from the side or the back of the box. The hole in the centre of the box allows for a support for the fixture, or, if used in combination work, the gas-pipe nipple, to come through. However, in combination work it may be preferable to have a sleeve to prevent the gas pipe from coming in contact with the wire. For straight electric work, where no gas pipes are used, this may be used also for a wall outlet.

Fig. 2 is designed for a wall box, where two conduits enter, both on the same side, which is a very common occurrence. This box can also be used to good advantage as a ceiling box when outlets come on the bottom of iron beams. The diameter, being small, allows the use of ordinary fixture shells.

The Chase nipple shown in Fig. 3, which is meeting with so much favor among electrical contractors, is constructed from a special grade of metal, having an exceedingly tough nature, and is made with a hexagon head, which allows the nipple to be easily screwed into coupling on end of conduit. The nipple is thoroughly painted with a special hard drying enamel that adheres firmly to the metal and will not chip off. In drawing in the wires the nipples are of special advantage, as they prevent abrasion and the wires are drawn much easier. These can also be used to great advantage at outlets where boxes are not to be used.

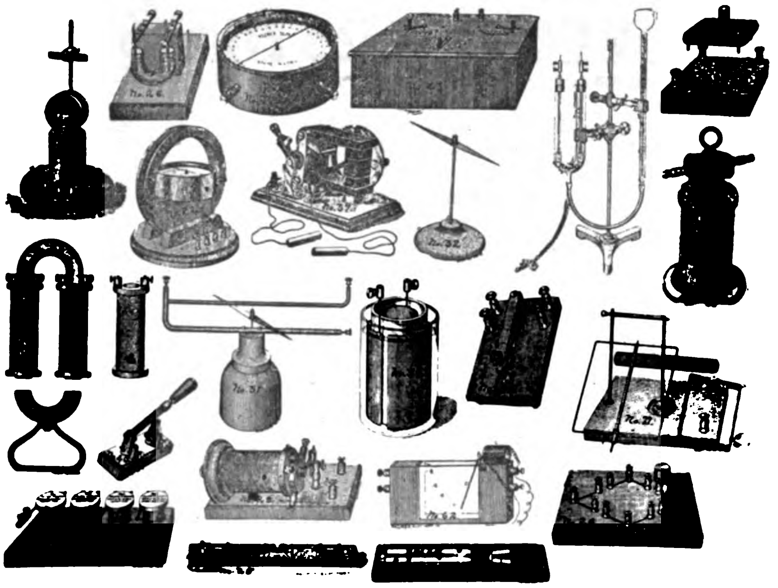
A booklet, entitled "Treatise on Knock-outs" is published by the Company, and will be mailed to anyone on application.

Experimental Electrical Apparatus.

THE experimental set of electrical instruments manufactured by the Palmer Electrical Instrument Co., of Philadelphia, is especially designed to meet the requirements of those engaged in the study of practical electricity or employed in electrical industries. To become familiar with the laws governing electrical currents, one must experiment with them, and this becomes most readily possible by use of the "complete experimental set."

The instruments are durably constructed and handsomely finished; they are thoroughly practical and moderate in price, yet flexible enough to illustrate all the fundamental principles of magnetism, electro-magnetism, voltaic electricity, electro-chemistry, electrical measurements, electro-magnetic induction, dynamo-electric machines, etc.

The apparatus shown in the illustration will be appreciated by instructors in physics courses, where many students perform the same experiments simultaneously; it is also adapted to the equipment of independent electrical laboratories, as an adjunct to



COMPLETE SET OF PALMER ELECTRICAL INSTRUMENTS.

courses in electricity, in manual training and high schools, Young Men's Christian Associations, etc.

Western Electric Fan Motors.

During the warm weather it is necessary to make places of business cool enough to enable the occupants to accomplish their usual amount of work and do it in comfort. Hardly an office, store, or any other place of business is nowadays without the means of creating a cooling breeze, and for this purpose it has been found that there is nothing better than the Western Electric 1898 desk and bracket fan motors. Their convenient size, three speeds, and good mechanism (all of which are described in details in Bulletin 2-F issued by the Western Electric Company), make them most desirable. A copy of Bulletin 2-F will be mailed to anyone requesting it.

The Western Electric Company has designed fan motors that can be connected up directly with 220 or 550 volt circuits without the interposing of any resistance. This company also states that three of its 110 volt motors or two of its 220 volt motors can be run in series on 500 volt circuits and the 550 volt motors can be placed on 600 volt circuits.

General Electric Lightning Arresters.

"Lightning Arresters," is the title of a short treatise, from the press of the General Electric Company, descriptive of the devices which it has developed for preventing injury to electrical apparatus by lightning. The introduction is a short examination of the qualifications necessary to a perfect lightning arrester, with a short disquisition on the special advantages of the magnetic blow-out. This is followed by concise descriptions of the arc and incandescent station arresters, already well known as types

"A," "AA," and "B." Greater space is given to the more recently developed lightning arrester for direct current circuits up to 850 volts, and to the G. E. short gap arrester, especially designed for alternating current circuits and in use on almost all of the great electric power transmissions of the West. The booklet is well written and printed, the illustrations are excellent, and the diagrams of connections clear and distinct. We understand that "Lightning Arresters" will be furnished by the supply department of the General Electric Company on application at any of the sales offices.

Stanley Electric Manufacturing Co.

The Stanley Electric Manufacturing Company, Pittsfield, Mass., have just moved their New York offices from No. 39 Cortlandt street to the new Empire Building, corner Broadway and Rector street. Their offices there are on the tenth floor, and will be more commodious and better adapted to accommodate the conditions of their growing business.

ADVERTISERS' HINTS

ZIMDARS & HUNT, 127 Fifth avenue, New York, have placed on exhibition at the Electrical Show a full line of switchboards, panel boards, feeder boards, knife switches, automatic switches, automatic motor starters, etc. Their catalogues "A," "B' and "C" are descriptive of these goods, and may be obtained on application.

THE GREENVILLE ELECTRIC CO., Greenville, Pa., are refilling fuse plugs at two cents each.

THE H. W. JOHNS MFG. CO., 100 William street, New York, advertise toggle clamp cable insulators and trolley line materials.

J. J. McCABE, 14 Dey street, New York, calls attention to his double-spindle lathe as an ideal tool for repair shops. It is practically two lathes in one.

THE AMERICAN ELECTRICAL AND MAINTENANCE CO., 451 Greenwich street, New York, are introducing a tool for turning down commutators while the armatures are running in their fields. It comprises a carborundum wheel run by belt power from the armature, and takes off a fine cut, making the surface smooth and true to the bearings and brush holder studs.

THE WESTINGHOUSE ELECTRIC & MFG. CO., Pittsburg, Pa., advertise a great variety of motors to suit all classes of service.

THE GENERAL ELECTRIC CO., advertise their '98 models in fan motors.

THE WARREN ELECTRIC & SPECIALTY CO., Warren, Ohio, offer four cash prizes for the best name to christen their anti-trust incandescent lamp.

THE AMERICAN ELECTRIC FUSE CO., 521 Wabash avenue, Chicago, Ill., invite requests for prices on their combination lightning arrester and cut-out for telegraph and telephone instrument protection.

THE AMERICAN DISTRICT STEAM CO., Lockport, N. Y., under the heading, "How Coal Bills Were Paid for an Entire Year," tell how this may be accomplished by the use of the Holly system of heating by exhaust steam.

THE SPRAGUE ELECTRIC CO., of New York, are advertising the conduits for interior wiring, formerly made by the Interior Conduit and Insulation Co. These goods have long been standard.

PERU ELECTRIC MFG. CO., Peru, Ind., advertise porcelain sundries.

DE VEAU & CO., New York, have taken an order from the U. S. Government for fourteen sets of telephones for submarine divers.

W. S. TURNER, M. S., has removed his office to the new Washington Life Building, No. 141 Broadway, corner of Liberty street, New York, where he will hereafter conduct the business of electrical and mechanical engineering and construction. He will be pleased to be favored with calls and inquiries of friends and clients.

A CORRECTION.—In the article on the St. Anthony Falls water power plant it was stated that the water wheels which run the two 100 k. w. exciters were built by the D. S. Morgan Water Wheel Co., of Dayton, O. This was an error. The wheels were built by the S. Morgan-Smith Co., of York, Pa.

THE BUCKEYE ELECTRIC CO. are finding a large sale for their special anchored filament 220 volt lamp. Life and candle power tests in actual service, prove this special type of "Buckeye" lamp to be among the leaders in its class. Catalogue and prices can be had from Cleveland, or 753 Monadnock Bldg., Chicago.

ELECTRIC TRANSPORTATION

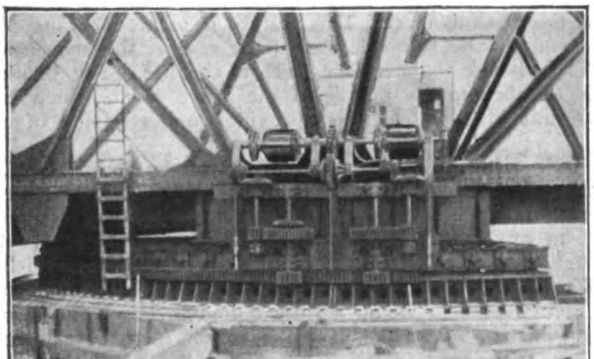
Electric Power on a Big Chicago Bridge.

BY J. R. CRAVATH.

THE Chicago & Northwestern Railway last month put in position at Chicago one of the most important railway drawbridges in the country. It replaces an old bridge and over it all trains entering the Northwestern passenger terminal must pass; the numerous through trains leaving for all parts of the Northwest and the heavy suburban business done by the road over its three lines running out of Chicago. Not only must the regular trains arrive and depart over it, but trains cross it going to and from the yards which are on the side of the Chicago River opposite the depot. The only other railroad bridges in the city which equal it in frequency of trains are the Metropolitan and Lake street elevated railroad bridges.

As a matter of course electric motors are used for swinging this bridge, the steam swung drawbridge being a thing of the past where electric power is available for the purpose. The contract for the electrical part of the bridge equipment was let to Geo. L. Nichols & Bro., of Chicago, who are old timers in this work and who carried it out with their usual promptness. There were no new electrical problems in connection with the bridge, but the peculiar mechanical structure required some new features in mechanical design.

The bridge is swung with two 30 h. p. motors furnished by the Jeffrey Manufacturing Company, of Columbus, O. They are of the enclosed type very similar to a railway motor. The circuits are arranged to run them either two in series, two in multiple or each one independently from a 220 volt circuit. The power is furnished from the depot lighting and power plant, a short distance from the end of the bridge, of which A. J. Farrelly has charge. It is the custom at present to operate the



ELECTRIC MOTORS ON DRAWBRIDGE OF CHICAGO & N. W. RAILROAD, CHICAGO, ILL.

two motors in series as this gives the greatest torque with the least current and so far has given speed enough for practical purposes. Later in the season when the bridge is "limbered up" and river traffic is heavy it may be necessary to increase the speed by operating motors singly or in parallel.

Plain rheostat control is used and the switching in or out of either motor is done with two double pole switches in the controlling cabin. The current from the power house is also usually kept off the controller and motors by a main double pole switch in the cabin which is closed when the motors are to be operated. The controller is the usual type furnished by the Jeffrey Manufacturing Company for this class of work and has a handle which is vertical when at zero and is moved either way from zero to go ahead and reverse. The motors are protected by a fuse of large capacity in the motorman's cabin and by a Cutter circuit breaker at the power house in the motor circuit.

Compressed air plays an important part in the control of the bridge. It operates the signals at the approaches and the catch which holds the bridge while it is closed for train traffic; lifts the rails at the ends of the bridge before it is opened and operates wedges which relieve the pivot of the weight of the bridge when it is not being swung. The only brake employed is worked by a foot treadle in the cabin and acts as a clutch brake on the motor shaft. No great braking power is needed with a bridge of this kind. The bridge is pivoted at one side of the center instead of under the center as swing bridges usually are. The weight of the bridge is carried by the pivot and by a carriage on the opposite side from the pivot. The motorman's cabin is located over the pivot and the motors are over the carriage just across from the cabin. The weight of the bridge is about 200 tons.

The object of the peculiar pivot and carriage mechanism is to prevent the end of the bridge from fouling the Kinzie street draw just north of it when both are open. By putting the pivot at the south side of the bridge instead of the middle the short space is gained which allows the two bridges to clear each other. The design is that of Engineer W. H. Finley, of the Northwestern road.

Electric Street Railways in Baltimore, Md.—Notes from the Field.

BY C. B. FAIRCHILD.

TWO companies, the Baltimore City Passenger Railway and the Baltimore Consolidated Railway Company, control most of the street railway mileage in the city, or about 300 miles of a total trackage. In the practice of both systems are found many interesting features, which may be included in the sum of modern standard practice, and are so made available for all who may wish to compare or improve their own practice.

The only remaining cable line, operated by the Baltimore City Passenger Railway is about to be transformed into an electric line. The overhead wires are up, the motors are bought and new power installed. It is interesting to note in this connection that this change was anticipated some time since by the management, or about a year and a half ago, when a change was made in the gripping device and method of operating the cable car. Formerly the cable cars were operated in trains, consisting of an open grip car and trailer. The train system still prevails, but the open grip cars have been converted into trailers, and the closed cars used for the grip car. These closed cars have 16-foot bodies, and when the change was made were mounted on Peckham trucks, and the Earl, or Broadway, grip was substituted, and is operated from the front platform. These trucks were provided with heavy axles, having key seats, and every feature to be readily adapted for electric motors. The open 16-foot cars were converted into trailers, and are run the year round. The same train method will continue now that electric power is to be substituted. After the change of grips the speed of the ropes was increased, but the accident record was reduced, owing to the position of the gripman on the end of the car, and since the change not a delay of any kind has occurred on this system.

The new motors, of which 85 equipments have been purchased, are of the Westinghouse No. 49 type, and were selected because of the previous excellent record made by the Westinghouse motors on the present electric line, which have now been in operation about four years, and during that time not an armature has been destroyed out of the 423 equipments; two only have been injured by lightning, and these required only slight repairs. Two boys do all the winding repairs necessary on the armatures and field coils, making the expense for this class of repairs very light. This result is obtained by careful inspection by both the day and night men, and because of the practice of thoroughly overhauling the electrical equipment of each car every two weeks. The speed of the cars not being limited by city ordinance a very high rate is attained on some of the outlying sections. Considering the high speed and

heavy surface, there being many steep grades, the motor record is a phenomenal one.

POWER STATIONS.

Two electric and three cable stations now generate the power for operating the entire system. The manager is now considering the advantage of erecting a central station from which all the lines can be operated electrically. The plans contemplate the installation of direct coupled units, driven by engines of the latest approved type.

The principal electric station now employed is located on Light street, and the steam is generated in Campbell & Zell boilers, equipped with Roney mechanical stokers, in which George's Creek coal is employed.

The electric equipment of the station is all of Westinghouse manufacture, and the development has been as follows: First. Three units of 500 kilowatts capacity each, the multipolar generatirs being belt-driven from an Allis-Corliss high pressure engine. About eighteen months ago a direct coupled unit was installed, consisting of a 750 h. p. Rice & Sargent engine, running 90 revolutions per minute. The peculiar features of this engine are two eccentric rods for operating the steam and exhaust valves separately. The generator is of 500 kilowatt capacity, with a rated output of 910 amperes, but has been run up to a load of 2,100 amperes for 20 minutes without injury. Since the installation of this machine there has been no change or adjustment of the brushes, and no repairs have been necessary. It is stated by the engineer in charge that this engine, although running at ninety revolutions, consumes less oil than the other engine with a speed of only 66 revolutions.

The latest addition to the station is a motor-driven 900-volt booster, which has just been installed by the Westinghouse Company. This has been found necessary in order to supply the current to a seven and one-quarter mile line, on which are heavy grades, and at times an excessive amount of traffic, owing to the location of a bicycle colosseum which sometimes attracts as many as 20,000 people a day.

The station is equipped with Wurtz's lightning arresters and tank arresters; the Wurtz arresters are also employed on the line. This locality being subject to frequent and heavy electric storms the lightning arresters become important features, but this station is never required to shut down during a storm.

REPAIR SHOP PRACTICE.

In the woodworking department only one machine is employed; this is known as the Universal woodworker, and was manufactured by M. B. Tidey, of Newark, N. J. This machine can be adjusted to do all kinds of woodcutting, including mortising and boring.

The iron working tools are large and are ample for a still larger shop. Among the shop "kinks" we note a peculiar arrangement of the template, adjusted to a large drill press, by which the gear cases, which are manufactured by the company, are readily drilled and fitted. There is also a mould for making lead gaskets for use on the Zell boilers. These gaskets are used instead of those made of rubber, which are too expensive owing to the great quantity required for this type of boiler. The lead gaskets are first cast as a round band, having corrugations on each side. These are then placed over an adjustable mandrel, and by means of a short lever, the bands are stretched into an oval form, and to an exact fit for boiler opening.

A home-made armature and axle lift is employed in the repair pits for removing armatures or axles. This consists of a low platform, mounted on castor wheels, having handles for drawing it about. Iron posts at each corner support a second platform on which is mounted a short shaft, carrying two five-inch sprocket wheels. The shaft is moved by means of a crank handle, having a three-inch pinion meshing into an eight-inch gear on the main shaft. The gear and pinion employed were taken from the platform equipment of a type of brake formerly employed. Over the sprocket wheels a chain is looped with the lower ends attached to a vertical plunger, consisting of a three-inch pipe, which carries on its upper end a swiveled curved seat to fit an armature. By the motion of the crank the seat is lifted up or down with a range of twenty-five inches. By this means an armature is readily removed and transferred to any part of the pit and rolled out upon the floor without any heavy lifting.

Axles are removed by the same device; one of the pits being especially constructed with a removable section of rail so that it can be operated. The car is placed on the section and lifted by means of four Yale triplex hand hoists. By removing the short section of track the axle is lowered by the lifter and swung around and removed to any part of the pit, the same as described for the armature. A new set of wheels and axles are replaced in the same manner without any excessive lifting on the part of the employés, and without straining the car body, as is the case when only one end of the car body is jacked up for the replacing of wheels.

The car wheels are purchased for the most part from the New York Car Wheel Works of Buffalo.

ROLLING STOCK.

In remodelling the old grip cars for use as trailers, the position of the side truss rod was changed, or, rather, they were lifted to give a greater supporting power. The middle portion consists of a straight length of flat iron bar two inches wide let into the post just below the windows, from the ends of which the truss rods proper descend to the end of the car sills, each end rod being provided with a turn buckle for adjustment. Cross truss rods are also employed with each cross sill.

The standard lettering for all cars, both for the name of the company and for designating the routes, is a plain block letter put on with stencil plates, brass stencils being employed. The exterior decorations are very meagre, and consist of a neat border on each end of the main panel. The cars are numbered at the middle of the sign panel, and on the corner of the dashboard. The inside number is placed near the register. Twenty new open cars have recently been purchased from the American Car Co., of St. Louis; these are 31 feet over all.

The deck lights for all the cars are of white glass, except those in the end which are colored for the different routes. A considerable saving is effected by employing plain glass, as when broken it can usually be placed by strips cut from the broken window panes. The cars are all provided with 10 incandescent lamps making them especially bright and attractive at night.

A novel method of operating the brakes has been devised by the master mechanic, and adopted by the company. This consists of a short vertical lever pivoted in a bracket attached to the suspension bar of the truck near the side bar. To the upper end of the lever the brake chain is attached, and two rods, one above and the other below the pivoted point of the lever extend in both directions to the end of the floating lever of the brake mechanism. Each end of the car at diagonal corners is provided with the same equipment, and the side rods of each equipment become in turn anchor rods for the opposite ends of the floating lever. This feature is secured because the vertical rod on the idle side rests back against the suspension bar. The pivotal support being below the bar. The floating lever is attached to the middle of the brake beam, which is a flat bar, and rides in channels provided on each side of the truck.

The ends of the brake bars are reinforced by a thin thimble of metal, which is shrunk on, and which takes the wear from the sliding motion. These thimbles are rounded at the outer edge to prevent any cramping of the brake beam should there be any difference in the travel of the ends. The Christy head has been discarded, and the brakeshoes are cast with a flat lug, which admits of their being readily bolted to the brake beam. Springs hold the shoes free from the wheels in the usual manner.

The cars are all equipped with a home-made fender and a wheel guard. The fender is composed of a frame work of pipe carrying rope netting. There are two main bars, and the fender has the form of a fish mouth. The fender is proving very efficient, as the records show that 299 lives have been saved by them since their adoption in 1895. The wheel guard consists of small iron rods looped, which are fastened to a bar hung in front of the wheel near the paving, and which has the appearance of a large comb, with the teeth parallel with the roadbed.

DISCIPLINE.

It is seldom that one finds a body of railway employés more faithful or more loyal to the company than the men employed by the Baltimore City Passenger Railway Company. This the General Manager, Mr. F. L. Hart, ascribes to the manner of administering the discipline, and the treatment given to the men by the heads of the departments, as much attention being given to this branch of the service as to that of the mechanical department.

Orders are issued to the superintendents and foremen that all men serving under them be treated with the same respect and consideration that they themselves would expect to receive were their positions reversed. The use of profane or angry epithets in dealing with an employé is forbidden, and the men are encouraged to have the same respect for each other. The superintendents and heads of departments are granted two weeks' vacation each year, with full pay, and they are allowed to go where they like. Provision is also made for some of the assistants to visit other cities, where they may study the street railway practice of other lines. The master mechanic has been delegated at different times to visit car and truck manufacturing establishments in order that he may get the benefit of such practice as may be made available to local conditions. Liberal dealing in this direction pays in the estimation of the manager a hundredfold.

The car men are required to wear service stripes on their coat sleeves to indicate the number of years of continuous service with the company. A new stripe is added every five years, and among the thousand or more employés 150 or more are now wearing a service stripe; while two of the men have seven stripes, two others five, and two four, each. It is observed that men wearing service stripes receive more respect from passengers, and in case of difficulty they seem to have more power in enforcing a compliance with the rules. The men themselves all strive for clean records that they may secure the stripes. In case it becomes necessary to inflict any penalties, or discharge for any cause, it is done only after careful investigation, and by vote of three members of the Board, detailed for the purpose; even the General Manager does not assume to exercise authority in these matters without the co-operation of some of his associates; this insures justice being done to all concerned. The men are required to pay for damage to the car from careless running, and for flat wheels.

MUNICIPAL REQUIREMENTS.

The aggregate city tax imposed on the companies by the local authorities amounts to 20 per cent. of the gross receipts. There is a special tax of 9 per cent. for Parks, and in addition to car license a real estate tax, so that the company makes a practice of charging off 20 per cent. of the gross receipts each day to meet these requirements. Notwithstanding this a dividend of 10 per cent. is usually paid.

A liberal system of transfers has been adopted and a different colored ticket is employed for use at certain periods during the day; the days being divided into three periods to correspond with the color of the ticket. A Steadman type of ticket is employed.

In the matter of accident cases it is the policy of the company to settle promptly before the cases can be taken into court. A regular physician is employed, who spends two hours every morning at the Company's office, looking over and investigating the accident reports. Careful records are made of each case, which are then filed in a ready reference case.

Uniforms worn by the men are made from the standard metropolitan police blue cloth, and the men are allowed to purchase them for themselves. In engaging new men no deposit is required, but all are required to be bonded in a fidelity company, for which the men pay five dollars for the first year, and after that three dollars per year.

Mr. F. L. Hart, the manager of the company, was formerly in the employ of the Third Avenue Railroad Company, New York, as Chief Engineer at the 145th street cable power station, and was later with the Metropolitan Street Railway Company of New York. He attributes his success in the management of the Baltimore system to the valuable experience he had with the above companies, and has only kind words expressive of his regard for his superiors in these companies.

Signs for Trolley Fenders.

"In a brief visit to the borough of Brooklyn, the other day," said a Manhattan boroughite, "I saw on the fender of a trolley car a single sheet poster printed with the announcement of a theatre. I should think that as bill boards the fenders of trolley cars would serve admirably, especially for pictorial work, for circuses, for instance. A trolley car with its fender covered with pictures of lions and tigers, and so on, coming toward the beholder at a high rate of speed, could not fail to be impressive."
—New York Sun.

TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work.—XI.

BY A. E. DOBBS.

MANHOLES are also a necessary part of conduit work. They should be large enough to allow a man to get into and do the necessary work of splicing, etc. They should also be lined with brick set in cement; and the floor may be cement, with a drain in the bottom, or if the soil is porous enough, have no floor at all, except some coarse sand thrown in the bottom to keep it clean (Fig. 34).

They should not, as a rule, be more than 500 feet apart, though 1,000 feet of cable can be put through in one length, but where this is done it is better to select the middle manhole and pull both ways from there, as described in a previous chapter on aerial cables. The ends of the ducts in the manholes should

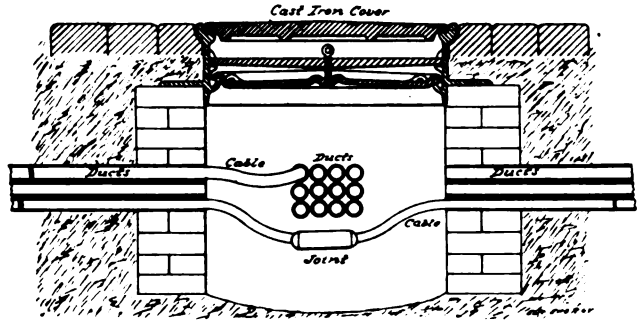


FIG. 34.

also be reamed out, so that no sharp corners, or projections, can possibly mar the cable. They should also have cleats or hangers around the sides so that the cable can be kept out of the way.

There is a diversity of practice in regard to keeping water out of ducts and manholes. Some will use their utmost endeavors to seal up both ducts and manholes, so that no water can possibly get in—but it does just the same—while others make no effort to keep the water out, but put a drain connection at the bottom of each manhole. Others still make no effort either to keep water out or drain it off. If they should open a manhole and find it full of water, they simply pump it out till their work there is finished, and let it go at that. If the soil is sandy or porous, it will absorb all the water liable to accumulate in any conduit system. The manhole covers should, however, be as nearly watertight as possible. Water does not hurt a lead covered cable, and there is no particular use in trying to keep it dry underground.

In London it was the practice to even fill the conduits with water, presumably to keep the cable as cool as possible, and counteract the effect of steam heating pipes. In some downtown districts in New York City, the temperature of the ducts, in places, is almost that of boiling water.

In getting a cable into a duct the first thing is to get an inch rope pulled in. There are various ways of doing this; the simplest way is to pull in a No. 14 steel wire as the duct is laid, and when needed hitch a rope to it and pull it through. Another method much used, is to have several hundred sticks about four feet long, with brass screw joints on each end, one being a male and the other a female thread. As fast as one stick is pushed into the duct another is screwed into it, and so on, till the next manhole is reached, when the rope is hitched in to a swivel, made to screw into the end of the stick, and the man at the next place pulls it through, unjointing the sticks as fast as they arrive.

T. J. Cope, of 3244 North 15th street, Philadelphia, advertises a machine that works its own way through the ducts, cleaning out dirt and other rubbish as it goes along. According to his advertisement he has cleaned and threaded about 9,000,000 feet of duct with it.

To fasten the rope to the cable, spread out the end and pass down over the end of the cable for about two feet, then lash it

tightly, with marlin twine, or wire. Some contractors use an iron clamp that passes down over the end of the cable, similar to that on a wagon tongue, when a couple of holes are punched through the cable, and rivetted or screwed down, the rivets passing through holes in the clamp for that purpose. A loop in the end of the clamp permits of fastening the rope.

To pull through a length of 500 or 1,000 feet will require considerable power; cable contractors use a winch and capstan for this purpose, so constructed that it (the winch) can be placed

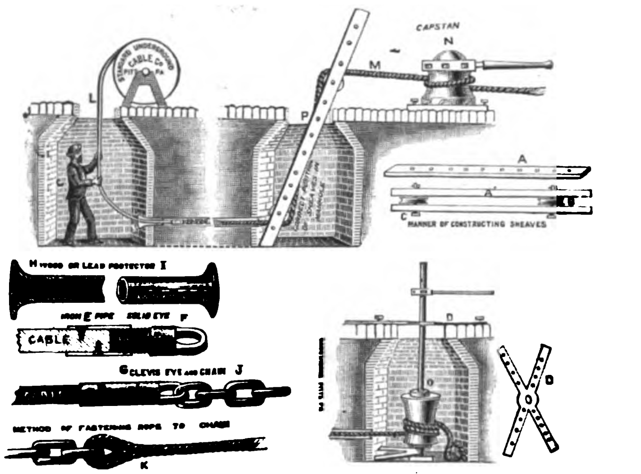

FIG. 35.

in the manhole, while the men can work the capstan bars above ground. But where there is not cable enough to justify this expense, double pulley blocks will do almost as well. The method of using capstans in different positions is illustrated in Fig. 35, which shows the apparatus employed by the Underground Cable Co., Pittsburg, Pa.[1]

In districts where few wires are taken off, a heavy pole probably furnishes the simplest method of distribution, using either double arms faced at right angles to each other, or a circular iron ring about 6 feet across, and held in place by braces made to fit ring and pole. The ring is of angle iron with the lip of the upper angle turned outward. Angle braces are made to fit this ring and pole, both above and below. Around the outer projecting lip of the rim are drilled ¼-inch holes about 4 inches apart, and through these is passed a bolt to connect two porcelain knobs—one above and one below the lip—thus making

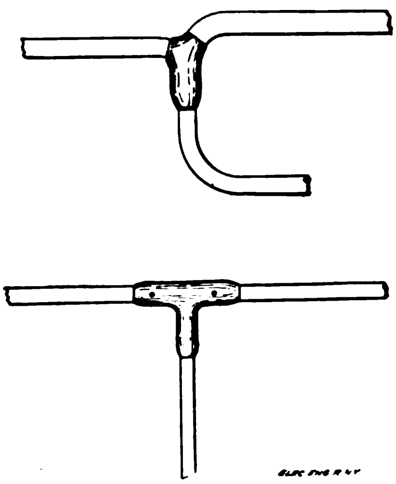

FIG. 36.

place for two wires at each drilled hole. Where a large number of telephones are to be served to one building, as a large office building, the best way is either to come up the side of the building to the roof, or else to take the cellar, and distribute from there.

It is sometimes very convenient to divide a cable into several parts, as described before, but with a difference. Suppose we have a 200-wire cable, which we wish to distribute at four points, A, B, C and D. At A, we will need, say, 50 wires. We take the first 50—for by this time the cable should be numbered at the office end. Now, as we may want some of these wires again, we will not cut them here, but merely "tap in" (multiple) and continue to the next terminals.

From this "split" we run a short 50-wire cable to its terminal outside. At the next station, B, the next 50 wires are tapped; and it might be well to also tap it on the first 50 at this point, as they may be needed to help out the distribution; for one terminal might have more subscribers than it has conductors, while another will have plenty of conductors to spare, and it may be found very convenient to tap some of them. Then the cable may be changed to one of 100 conductors, and connected to C and D, the same as at A and B. Some companies, however, would bring the whole 200 conductors into each terminal. We suppose here we ought to stop and give some directions for making a cable splice.

Bring the two ends together and past each other about a foot or more, according to the amount of end to be wasted. Then strip the lead back till there is about a foot between the two lead sections. Then take a piece of lead pipe a little larger than the cable, and a little longer than the space that separates them, and slip it back over one of the ends. In making joints twist the two ends of the wire together, but before doing so slip a sleeve either of paper or cotton over one of the wires so that when twisted it can be slid over the joint. Cable joints are not soldered. In making joints distribute them as nearly equally as possible, over the space between the two ends to prevent bunching.

When the joints are all made and the short lengths of tube slipped in place, pour them with a mixture of paraffine and beeswax, or whatever is being used; then slide the lead sleeve so as to cover the two ends, and make a "wiped" joint. If the men handling this work don't know how to wipe a joint, hire a first-class plumber to do it, and be sure that the joint can be depended on not to leak, though the plumber should understand this.

In making a tap (split) joint, three ends are brought together instead of two. (See Fig. 36.)

Some men like to leave a hole in a joint sleeve, and fill it full of insulating compound, soldering up the hole again afterward.

REMARKS ON ELECTROLYSIS.

With wood or tile ducts, the "ground" on the cables should be so evenly distributed over the entire system that there should be no trouble with electrolysis. As said before, the same class of duct should be used even to the foot of the pole, or, if it is necessary to use iron pipe, do not extend it into the earth more than two or three feet from the top of the ground, and wrap that part of it in burlap, thoroughly soaked in tar, to prevent direct contact. Of course a cable up the side of a pole, or house, needs some protection, but tile can be found to make the bend at the foot of the pole, and galvanized sheet iron bent over the cable and nailed down, is almost as efficient.

Now, the only trouble from electrolysis comes from street railways, or power circuits, with a ground return, and is caused by an escape of current from the ground wire. Suppose there is a loss in the trolley wires, from the power house to the end of the line, of 250 volts, as frequently happens. Some of this is used in overcoming the resistance of the conductors, but a large part of it is lost in the ground return, and a great deal of it strays away to water, gas, or cable pipes in the vicinity. Now, where the current enters these pipes there is no harm done, but when it leaves them again like a freebooter that it is, it takes part of the pipe along with it. (The text-books say that it sets free oxygen, which enters into active combination with the metals, but the effect is just the same.)

Its presence is indicated by decay and pitting of the pipes affected, and a visit to the power house should be made forthwith. If it is found that the negative bus-bar is the one connected to ground, there is nothing more to be done there, unless it may be that the ground return is not heavy enough, in which case you may be able to make some arrangement in regard to it. (If a bonded track return only is used, it is a very uncertain factor.) If the positive bus-bar is connected to the ground, it should be changed.

But if everything is all right in the power house, there is only one thing to do: to go back to where the damage is being done and connect the cables or pipes to the track return

[1]Fig. 35 is reproduced by permission from a handbook by the Standard Underground Cable Co., Pittsburg, Pa.

with a heavy copper wire; and if any more signs of decay are found to continue to connect it at intervals of every half mile or so, that it, provided it parallels the track that far.

All this will have a tendency to make a noisy cable, but it cannot be helped.

Electrolysis of course does not bother aerial cables to any extent.

As the static capacity, inductive and electrolytic effects are largely increased by the proximity of the earth, underground are therefore not as desirable as aerial cables, for with an extensive underground system metallic circuits become almost a positive necessity and the only thing to be said in favor of an underground system is that it is not affected by storms and, therefore, gives continuous service. It does not obstruct the streets with hundreds of wires, some of which are liable to break and cross electric light and trolley wires.

The city of Pittsburg has had a lively experience of that kind in one or two blizzards last winter, when men were shocked, horses killed and the rest of the citizens terrified into nervous prostration—at least the newspapers said so.

The static capacity of bare wires overhead varies from .0144 to .0160 microfarads per mile, while underground paper cables vary from .06 to .10 microfarads or from five to seven times more and induction effects in about the same proportion.

The nearer we get to the earth, the greater the wave distortion and success in telephony depends very largely upon our ability to preserve these waves in their original form.

The following specifications follow closely those laid down by the different Bell companies:

1. Each conductor shall have a diameter of 40 cir mils (No. 19 B & S, though they are sometimes larger than this and may be even as small as No. 22), with a copper conductivity of 98 per cent.

2. The conductor shall be insulated, with two paper tapes, twisted in pairs, the length of the twist not to exceed three inches, and formed into a core arranged in reverse layers.

3. The core shall be inclosed in a pipe composed of lead and tin, and the amount of tin shall not be less than 2.9 per cent. The pipe shall be formed around the core and shall be free from holes or other defects and of uniform thickness and composition.

4. The average electrostatic capacity shall not exceed .080 of a microfarad per mile, each wire being measured against all the rest and the sheath grounded; the electrostatic capacity of any wire so measured shall not exceed .085 microfarad per mile.

5. Insulation from 100 to 500 megohms (100,000,000 to 500,000,000 ohms) per mile at 60° F. and a conductor resistance of not more than 47 ohms per mile connected to terminals.

Denver Telephone Sub-Station.

To accommodate its increasing business in the residence district in the city of Denver, the Colorado Telephone Company has built a sub-station at the corner of York street and Colfax avenue. The structure, which will be one story and a basement, will be completed by July 1. When the station is finished it will have a capacity of 2,100 subscribers, but at the outset probably not over 250 instruments will be connected to the exchange. The sub-station is located about two miles from the company's building on Lawrence street, and the two exchanges will be connected by trunk lines.

A VOLUNTEER SIGNAL CORPS. The U. S. Senate has passed a measure authorizing the enlistment of a volunteer signal corps, two-thirds of whose members must be expert electricians or telegraphers.

Entertainments at the Chicago Convention.

We open our forms to note that the Chicago Local Reception Committee on Monday arranged as follows for the entertainment of visiting members and friends of the National Electric Light Association: Reception at the Auditorium Monday evening; excursion on Lake Michigan Tuesday evening; lecture by Mr. Joseph Wetzler Wednesday evening; coaching parties through the Parks and Boulevard system and suburbs, with luncheon, for ladies, for Tuesday and Wednesday, during the hours of meeting. There are six papers and five topics for discussion.

MISCELLANEOUS

Current Transformers.—I.

BY CHARLES T. CHILD.

THE extending use of several different varieties of electric current, each of which possesses qualities fitting it especially for particular applications in the arts, has called into existence a number of machines and methods for the transformation of one kind of current into another. Electric currents may be broadly divided into three classes: direct continuous, direct pulsating, and alternating, and these are further distinguished as currents of constant volume or constant difference of potential between the two sides of a conducting system, and as single-phase or polyphase.

Three varieties of direct current are in extended use, the constant potential supply systems for lighting, railway work and electrolysis; the constant current supply systems for arc lighting, electrolysis and occasionally for power transmission and other purposes; and the pulsating current for arc lamps, in telegraphy and, less frequently, for electrolytic and similar purposes. The most frequent occasion for transformation between one variety of direct current and another is when it is desired to change the voltage of a constant potential supply system. It is not necessary here to go into any description of alternating current voltage transformers, since these are of peculiarly simple and well known construction.

The only methods for the voltage transformation of direct currents are by the use of motor-dynamos or dynamotors, and of accumulators which are connected in a certain arrangement for charge at one voltage and reconnected so as to give a different voltage in discharge.

The motor-dynamo is, as its name indicates, a combination of a motor receiving the current to be transformed and driving a dynamo giving out the variety of current desired. Perhaps the most frequent use of this combination, at least in large sizes, is for "boosting" the terminal voltage of an electric light or railway feeder, the supply current being fed to it through a motor-driven series-wound dynamo for this purpose. The dynamotor is a machine having a single field and an armature carrying two windings, one for the primary and the other for the secondary current. These machines have given great satisfaction, especially in small sizes, being much used in lieu of the cumbersome and uncleanly battery for telegraphing, etc. Their efficiency is high, their running smooth and sparkless, owing to the balancing effect of the two armature windings eliminating field distortion, and their output for weight and cost is fairly high. They present, however, a formidable disadvantage not shared by the motor-dynamo, in that the two sides are electrically absolutely interdependent and the voltage of the secondary a fixed and invariable function of that of the primary. Hence any fluctuations in the primary voltage are immediately evident in the secondary, and cannot be compensated as in the case of the motor-dynamo.

Of much greater importance and interest is the transformation of alternating into direct currents and vice versa. The alternating current in any of its forms is, owing to the readiness with which it lends itself to voltage transformations, peculiarly adapted for long distance power transmission. But while such currents may be generated in machines of great simplicity and at almost any pressure and transmitted efficiently to great distances there are certain uses to which they are not applicable in the present state of the art, and certain others to which they can never be applied. Among the former are series arc lighting and electric traction, although it is likely that the difficulties now existing preventing their employment for these purposes will be overcome. For electrolysis, an enormously and increasingly important branch of electrical application, they are totally inapplicable, and, for the same reason, they are useless for charging accumulators.

On these accounts there exists a demand for means whereby the alternating current may be transformed into some variety of direct current. Alternating current systems of supply for lighting and power lack only the one element of capacity for storage and "steadying," possessed by direct current systems in

connection with a battery of accumulators, to be almost the ideal for central station distribution, and this capacity is given them by the reversible transformers presently to be described.

While there is less occasion to transform direct current into alternating this may be easily accomplished whenever desired.

Another set of transformations of great importance is the alteration of the phase relations and distribution in polyphase alternating systems. An example of this is shown in the Niagara-Buffalo transmission, where quarter-phase currents are generated, transformed into three-phase currents for transmission on account of the saving in copper effected by the use of this variety of current, and again transformed into quarter-phase current as a preparation for further transformation into direct current at the receiving end of the line.

One of the first current transformers to be used was the ordinary make-and-break mechanism of the induction coil, giving an interrupted or pulsating current in the primary of the coil and an alternating current of great complexity of wave form in the secondary.

The commutator, introduced by early experimenters to rectify the currents of magneto machines, and now in use for an identical purpose on all forms of direct current dynamos, is the prototype of the rectifier, a machine used with more or less success for the rectification of single phase alternating currents and principally applied for supplying current to series arc systems. In its simplest form the rectifier may be regarded as a revolving reversing switch which reverses the direction of current flow at the moment when the current itself reverses direction, thus giving currents all of one direction in the circuit to which it is connected. It is evident that such a current is of a pulsating character, however, because the effect of the rectifier is simply to turn the current impulses all in the same direction without at all modifying the form of the wave.

Obviously the rectifier may be made in a number of simple ways. It generally consists of a commutator of an even number of segments, alternate segments being connected together and to the source of supply of alternating current, and two or more brushes taking off the rectified currents, either the commutator or the brushes being driven synchronously so that the brushes pass from one segment to the next at the instant of zero flow.

Instruments of this character have been used with considerable success for series arc lighting, notably in England, and it is stated that the pulsating character of the current derived from them is not objectionable, but rather advantageous, since the constant tremor produced in the lamp mechanism prevents the sticking of the rod. There are, however, two serious objections to its use which have prevented its general extension. One is that the maximum voltage on the lines is considerably in excess of the virtual voltage, and the other is that it is practically impossible to maintain the adjustment of the inductance and capacity of the line so that the instants of zero current and zero e. m. f. coincide. In a circuit containing 60 lamps and requiring 3,000 volts at its terminals, the maximum tension, assuming the alternator to give a sine wave, will be about 4,250 volts. This increase in the pressure is necessarily destructive to insulation and provocative of accidents. On account of the difficulty in maintaining the adjustment of the phase relation of current and e. m. f. there is always more or less flashing at the brushes of the rectifier, and while this is not serious with currents of 10 amperes or less, such as are used for arc lighting, it is an insuperable obstacle to the use of rectifiers of this type for large currents.

An ingenious modification of the rectifier, designed for charging storage batteries, is due to Pollak. The commutator has wide spaces between the segments and the brushes can be so adjusted that only that part of the e. m. f. wave higher in tension than the counter e. m. f. of the battery is connected with it, thus avoiding the energy loss that would be due to the momentary discharge of the cells if the applied electromotive force were at any time less than that of the battery.

The efficiency of rectifiers is very high, the losses being only those due to friction and in the motor, if a motor is used for driving. Despite their high efficiency they do not seem to be destined to ever meet with extended use on account of the difficulties of sparking mentioned above.

Another method of rectification that has been suggested employs an accumulator giving a voltage exactly equal to the maximum e. m. f. of the alternating current wave and connected in series with the alternator. Obviously the effect of this arrangement is to extinguish the impressed e. m. f. of the alternator in one sense and to double it in the other, giving rise to a fluctuating unidirectional current wave rising from zero to twice its original value, the total current flow and virtual voltage remaining the same. The cells are alternately charged and discharged but will gradually lose their initial charge on account of internal losses. Certain combinations of electrodes and electrolytes offer the remarkable property of a very much higher counter e. m. f. to currents flowing in one direction than to those in the other, and it has been proposed to use systems of this character for rectification. These methods all possess considerably more interest than value.

When the transformation involves large currents and when it is desired to obtain a direct current of greater smoothness than the pulsating variety delivered by the rectifier, resort is had to one of three methods which will now be taken up in detail and considered with reference to their application to various practical cases. These three methods are respectively the motor-driven dynamo, the single and double winding rotary transformer, and the ingenious machine of MM. Hutin and Leblanc termed by them "panchahuteur"—a term for which there seems no exact English equivalent.[1]

The motor-driven dynamo for transforming alternating to direct current may be composed of any variety of direct current dynamo, coupled or otherwise connected to either a synchronous or an induction motor. The latter is practically never used in large sizes on account of its low power factor, which introduces disturbing elements in the line, and because its speed is a function of the voltage of the supply current and hence liable to considerable variation. The synchronous motor, on the other hand, may always be adjusted for unity power factor by proper field magnetization, or it may be arranged to cause either lagging or leading currents in the line at will. Furthermore, its speed is dependent solely upon the frequency of the supply current and hence upon the speed of the generator furnishing it, and motor and generator keep perfect step together. Hence if the speed of the generator is kept constant that of the motor will be, perforce, also constant, a condition highly desirable in this class of work.

The advantages of a motor-dynamo of this type are that the direct current voltage is independent of that of the alternating current and may be adjusted through a considerable range if desired. The construction of synchronous motors, in which the supply current is received by the stationary part, permits the use of line voltages without danger and thus dispenses with the stationary transformers necessary with the other types of rotary converters. A further great advantage of the motor-dynamo is that in transmission work the frequency may be chosen independent of any consideration of the direct current end of the machine.

The disadvantages of this type are high cost and comparatively low efficiency as compared with the single winding rotary transformer and machines of its class and, ordinarily, the lack of self-starting ability. To start the majority of such machines they must first be driven up to synchronism by using the direct current end as a motor, or by the use of a small auxiliary induction motor.

Notwithstanding the comparatively low efficiency of this type of transformer, its advantages for most classes of work are very great. By careful design and proportioning of its two parts to work well together and by mounting the rotating parts close together on the same shaft, eliminating in this way belt losses, an efficiency of over 85 per cent. at full load may be obtained from machines of moderate size.

From this combination to the composite machine in which the motor and dynamo windings are combined on a single part, generally the rotor, and a single field used, is no great step. An immediate gain in size is assured by the suppression of one field, but many of the desirable features of the motor-dynamo combination are necessarily sacrificed, among them the inde-

[1]M. Georges Dary, one of the editors of "L'Electricien," says of this word: "C'est un terme d'argot parisien qui a été appliqué au hasard, lors de l'invention de cette interessante machine, par un M. Géraldy et qui a été malheureusement adopteé pendant plusieurs années. Ce mot d'argot, qui veut dire 'tout est bouleversé,' 'change dans la génération du courant électrique,' a prés pour racine le mot chahut, chahuter, qui n'est pas français, mais seulement parisien (et de bas étage) et qui veut dire, danser d'une manière, faire du bruit, etc." . . .

(It is a Parisian slang phrase that was applied by chance at the time of the invention of this interesting machine by a M. Géraldy, and which has been, unfortunately, adopted for some years past. The word, which means "all is overthrown," "all is changed in the generation of electric current," has for its root the word chahut, chahuter, which is not French, but solely Parisian, and of low origin, meaning "to dance extravagantly, to make a noise," etc.)

pendence of the alternating and direct currents. Such machines, especially in large sizes, are unsuited to any but the lowest frequencies, their rotation period being a function of the frequency and the number of poles, and high frequencies leading to very complex multipolar constructions or unmanageable speeds with increased hysteresis and other losses. These difficulties have greatly circumscribed the field of usefulness of the composite type of machine and have so far prevented its very extended use. No doubt the superiority of the single-winding rotary transformer has also contributed to the unpopularity of the double winding type.

Discussion of H. H. Cutler's Paper on Motor Regulation and Protection Before the Chicago Electrical Association.

A LARGE attendance of Chicago electrical men was brought out by the announcement that H. H. Cutler would lecture on the above subject, a short time ago. Mr. Cutler having made the matter a special study for the past six years or more and many of his audience being directly interested in the manufacture, design and use of motor regulating and protecting devices, the meeting was one of unusual interest and practical value.

In introducing the subject, Mr. Cutler spoke of the practically unlimited field now opening up for the electric motor in shop transmission, in which field it now has a sure foothold. The regulation and protection of these motors had given rise to what might almost be called a separate branch of electrical engineering. The regulation of an electric motor is always accomplished by reducing the voltage across some part or parts of the windings, according to the nature of the motor and the work to be done. A compound wound motor with provisions on the rheostat for cutting out the series windings and cutting resistance into the shunt field was spoken of as one of the neatest methods. A regulating rheostat of this kind with automatic underload release on all of the various speeds was shown. He also described in detail an elevator controller which relieved the strain on the field insulation when reversing. He advocated, for protection, the enclosed fuse, because it gave the kind of protection that the motor really wanted, namely, protection against overheating, whereas the circuit breaker took no account of the heat being generated in a circuit, but opened whenever the current exceeded a certain amount. Since heat is the thing to be prevented, protective devices operated by heat should be used. The objections made as to the unreliability of the open air fuse did not hold against the enclosed fuse, which always has a definite surrounding medium. He exhibited a new form of circuit breaker of his design which had the magnet coil in shunt with a low resistance. This resistance had a high temperature coefficient and would rise in resistance with an excess of current so as to increase the voltage across the magnet coil and cause it to trip the catch. The value of this form of breaker in motor work lies in the fact that it will permit an overload for a short time, but will never let it remain longer than the safety heating limit of the circuit permits.

F. S. Hickok led the discussion by describing the Waite method of motor speed regulation with which he had occasion to experiment. A peculiar motor was employed having four field poles which were connected so as to make it either a bipolar or multipolar machine—a bipolar when the like poles were adjacent to each other, and a multipolar when the like poles were opposite to each other. The armature had two sets of windings. By altering field and armature combinations a wide range of speed and torque were produced.

F. B. Rae told of certain characteristics he has used in the design of elevator and other motors which must be started with powerful torque, whereby the starting torque is obtained with the expenditure of less current than that used in running at full speed. This is accomplished by enlarging the relative size of the field magnets in a motor until they are worked about at the saturation point to start the load instead of over saturation as is usually the case. The field is then weakened for full speed running. A certain elevator motor so designed by him and working against a constant load with constant torque would start with 24 amperes and consume 34 amperes at full speed.

W. H. Merrill, Jr., speaking from the standpoint of the underwriters, heartily seconded any good words said about enclosed fuses. Not only were they valuable because they confined the arc and were more reliable than the open fuse but they also insured against the danger of getting the wrong kind of a fuse into a fuse block, which was equally important.

He favored an electrical control from an elevator car rather than direct mechanical control, by rope or otherwise. Mr. Cutler thought direct mechanical control the surer and simpler. F. B. Rae described a method of electric control from elevator cars which depended on the Wheatstone bridge principle.

Mr. Cutler, in response to some questions, favored the use of the motor as an electric brake in elevator service rather than some auxiliary electric brake appliance consisting of magnetic clutches and the like. He reasoned that since the motor was already there it might be used as a brake as well as to spend money on other braking apparatus, especially as the motor affords such smooth stops.

ELECTRIC LIGHTING

The Development of the Central Station.—I.[1]

BY SAMUEL INSULL, President Chicago Edison Co.

WHEN requested a short time ago by the chief of the Electrical Department of this University to deliver a lecture on some subject connected with central station work, I must confess to having had some misgivings in accepting the honor to appear before you this evening, remembering the disadvantages that a commercial man invariably feels in discussing technical matters before those having had technical training, but then I remembered that even within my own time (and I think I can still claim to be a young man) very little was known of the general distribution of electrical energy from a central station, and when I recalled that so recently as the early 80's it was necessarily the rule for "guessing to be a substitute for mathematics"(to use the words of the great pioneer in central station work), my misgivings were inclined to disappear, and I felt encouraged to talk to you on the development of the central station from the point of view of my own experience in following this, the latest of the great industrial developments of the wonderful era in which we live.

In referring to the development of the central station, it would seem hardly necessary to go at length into the history of the business, the origin of which probably dates from the work of the early experimenters whose efforts were directed to the perfection of series arc lighting. Whilst their work is entitled to the greatest possible praise, it should be remembered that the theory on which they worked, namely, constant current and varying potential, is a theory foredoomed to failure, when applied to the development of a system of general distribution for light and power purposes, the first essential of which is the necessity for a constant potential the quantity of current varying in accordance with the demands made by those desiring to use the energy, whether for light or power purposes. Nor does it seem to me a matter very pertinent to the present occasion to trace the rival claims as to priority of invention of the early experimenters on incandescent lamps. Which of them was the first to produce a lamp that could be brought to a state of incandescence by means of the electric current is hardly within the scope of our inquiry. Probably all of them, groping in the dark (now and then illumined by flashes of light emitted from their experimental glow lamps), contributed in a more or less degree to the perfection of the incandescnt lamp as now in every-day use; but so far as their contributing much that is substantial, in the development of a system of central station distribution, it is probable that up to the year 1880, there was but one man who realized that in solving the great problem of electrical distribution the perfection of a filament of high resistance, when placed in a hermetically sealed glass globe from which the air had been exhausted and connected in multiple arc across an electric circuit, was the first necessity to the distribution of electric energy in our cities from a central station system.

In Mr. Edison's application for a United States patent on a system of electrical distribution filed at Washington on February 5, 1880, he says:

[1]Through the courtesy of Mr. Insull and of the Purdue University, we are able to present our readers with the text of a lecture delivered on May 17, before the School of Electrical Engineering at Lafayette, Ind. An illustrated edition of the lecture will be published by the University.

"The translating devices for each house may be either for light or power, or both. For light, the electric lamp, consisting of an incandescing material hermetically sealed in glass (shown in other applications made by me) is preferred. This lamp is made of a high resistance in comparison with that of any electric lamps which, to my knowledge, have been proposed. In lights heretofore proposed the endeavor seems to have been to lessen the resistance of the carbon, none having been suggested of higher resistance than, say, 10 ohms; but I have discovered that a very much higher resistance, say 100 ohms, must be used, in order that a number may be economically and successfully used in a system."

The question of the high resistance of the translating device was the first stepping stone to success. Everybody prior to Edison had aimed at getting a low resistance lamp, I presume on the theory that the less the resistance of one the less the resistance of the whole series. He struck out on new lines. A high resistance lamp was naturally followed by a multiple arc system.

In writing of the necessity of a high resistance lamp, the applicant for the patent had in mind that a system of electrical distribution could be used at the same time not only for lighting, but for power purposes, if the motors were properly constructed, and this is evidenced by the next paragraph in his application, which states:

"The motors should be so constructed that each, with a constant flow or pressure of current, will give the exact power required. This requires that each motor should be wound with finer or coarser wire, and into more or less convolutions, which determine the maximum effect of the motor."

If you will search the files of the daily and technical journals, and the proceedings of various scientific societies on both sides of the Atlantic from the summer of 1878 up to and including the year 1882, you will find that the great obstacles in the way of an economical system of central station distribution were the difficulties of producing a lamp that would last, one requiring only a minimum of current, and a system of electrical distribution requiring a minimum of capital, so as to enable electricity to compete with then existing methods of illumination and power.

The lecturer then quoted the opinions of various scientists and experts as to the insuperable difficulties standing in the way of a successful system of subdivision and distribution of the current, and continued:

I personally well remember Sir William Thomson's visit to the Pearl Street station in New York, in 1884, when he saw the Edison feeder system first in operation, and the great interest that he exhibited in studying it, and his admiration for the work accomplished by Mr. Edison in this connection.

I have thought it necessary to thus quote at length some of the leading English authorities in electrical matters, as I thought it would be better in claiming for an American the conception of the true basis of electrical distribution for light and power purposes, to give you the opinion and views on the matter of distribution of our "kith beyond the sea" rather than to quote the views of American scientists who might possibly be considered more impartial to the work of their own countryman.

It is often said that the principles of constant potential multiple arc distribution and the use of feeders to maintain an equal and economical distribution of pressure, are self-evident propositions, following the lines of gas and water distribution; but when you have such high authorities as Conrad Cooke in 1879 failing to recognize any of these necessities, or Mr. Swan in 1880 only recognizing the principles of multiple arc, and in 1882 failing to recognize the importance and far-reaching results of the feeder system, and Dr. Siemens as late as November, 1882, two months after a central station was in operation in New York City, adopting almost the same views as Mr. Swan, you can not wonder at Lord Kelvin answering the question as to why someone else did not invent the feeder system by saying: "The only answer to this, that I can think of, is that no one else was Edison."

It would seem to me, with such authorities, that it is not unreasonable to claim that the development of the central station and distribution system connected therewith dates from Mr. Edison's work at Menlo Park. Mr. Edison had been engaged during the early '70's first as a telegraph operator in the Western Union service, and later working on the gold indicators in the gold room in New street, New York, during the stirring period of speculation in the precious metal which culminated on Black Friday in 1873. Prof. C. C. Law, now connected with the University of Missouri, had, I believe, charge of the indicating instruments, and it is a matter of some interest to record the fact that the first work Mr. Edison did of an inventive character which yielded him a financial return, was in connection with and while he was at work on the gold indicators in question. Subsequently he was employed in the interest of what is now the Western Union Telegraph Company in improving the now universally used stock ticker. This work was followed by brilliant and successful work in connection with the duplex and quadruplex and automatic systems of telegraphy, and the invention of the phonograph and that part of the telephone now generally used for transmitting purposes and known as the carbon transmitter. His attention to the possibilities of what is popularly called the subdivision of the electric light was probably the result of a visit he paid to Mr. William Wallace at Ansonia in the fall of 1878, where he saw some experiments on dynamo machines, and on his return to Menlo Park he started his experiments on a system of electric light and power, which culminated in the successful starting of the first central station, in the lower portion of New York City in September, 1882.

The public interest aroused in his work and the controversy as to whether it was possible for him to achieve anything that would be of commercial value is evidenced by the constant reference to the matter in the public press in 1878, 1879 and 1880 resulting in a panic in gas securities in London in 1878 and in New York in 1879. Probably the work of no inventor was more generally discussed on both sides of the Atlantic by laymen and technical authorities alike than was that of Mr. Edison on his electric lighting and power system. All kinds of comparisons were made as to the difference between the cost of gas and the cost of electricity. It was claimed by many that Mr. Edison could not possibly be considered as having succeeded in his work unless he could produce an illuminant that would compete commercially with gas. They lost sight of the fact that the character of the two illuminants was entirely different, and that there was no more reason for supposing that, if electricity were more expensive than gas, the cost would be a barrier to its use, any more than there is reason for supposing that gas should be considered a commercial failure because the poorest classes find it cheaper to use tallow dips. The probable reason for scientists and electricians doubting the possibility of a successful electric-lighting system being produced was that all previous experimenting on incandescent lamps had been, as I have already stated, aiming at producing a lamp of the lowest possible resistance, and consequently requiring the greatest possible amount of current, these lamps being run in series, whereas Mr. Edison, at a comparatively early stage of his work, realized that the first essential was a lamp of high resistance, and that the only way of approximating an even distribution of pressure was to run these lamps in multiple arc. Hence his application for a patent on a lamp with a high resistance filament, under date of November 4, 1879, and his application on multiple arc distribution in February, 1880. It was then but a short time before he realized that, although experimentally this might give him even pressure, the expense of the copper in his distribution system would be too great, owing to the necessity of increasing the size of his copper, as he got farther and farther from the point of generation. The result was that in August, 1880, he applied for his patent on a system of feeders to supply his system of mains at various points throughout the system, the effect being a compact system with current flowing in all directions from the central point of generation through feeders, by means of which even pressure could be maintained throughout a considerable area.

A still further step made by Mr. Edison was the realization that nothing very reliable in the way of a distribution system in large cities could be maintained unless the work was placed underground, and, as a result of his work of a little over two years, we find that in the early winter of 1880, Edison had a central station system experimentally at work at Menlo Park, N. J., having an underground two-wire system, with the homes of himself and his staff electrically illumined by incandescent lamps, motors at work in his laboratory, and, in fact, all of the essential features of what is to-day now so common from the largest cities to the smallest villages throughout the whole civilized world.

It was but a short time after the starting of the first central station, in New York, that Mr. Edison found himself looking for some more economical methods of distribution; and I well remember his first experiments on the three-wire system, when,

at his shop in Goerck street, New York, he placed a third brush on the neutral point of the commutator of a small bipolar Edison dynamo and demonstrated the practicability of the three-wire system.

At the same time that Edison was working on the three-wire system experimentally in New York, Dr. John Hopkinson was probably figuring out the same thing in England, and Werner von Siemens was engaged in similar work in Germany. The records of the United States, English, and German patent offices bear witness to the fact that these three men accomplished about the same results at about the same time, and as a consequence, between 60 and 70 per cent of the investment in copper was saved.

New Large General Electric 60-Cycle Rotary Converter.

IN the station of the Pennsylvania Heat, Light and Power Company, Philadelphia, Pa., has recently been installed by the General Electric Company the largest 60 cycle rotary converter yet constructed. It is a 16-pole machine, of 400 k. w. capacity, running at 450 revolutions per minute, and was designed to convert an alternating two phase current of 60 cycles frequency and voltage variable between 165 and 220 volts, into a continuous current at from 225 to 300 volts. It is designated QC 16-400-450 and stands 8 feet high on a base 8′ 4″ by 8′ 6″.

The field frame of this machine (Fig. 1) is heavily ribbed, divided horizontally and susceptible of movement along the base to allow of inspection of the armature and field coils. The bearings are extra long and of the General Electric self oiling and self aligning type, that at the commutator end of the shaft being provided with an end play device to keep the armature in constant motion in the direction of the length of the shaft and distribute the wear of the brushes over the commutator surface to avoid the wearing of grooves. The armature is of the ironclad type.

The commutator carried on a separate spider is of very ample surface, and has a large number of segments. To facilitate the removal of a brush for examination and replacement without varying the tension under which it runs, a brush holder of unique design has been devised. To remove the brush the prolonged end of the brush holder is disengaged from the brush holder by a slight end motion.

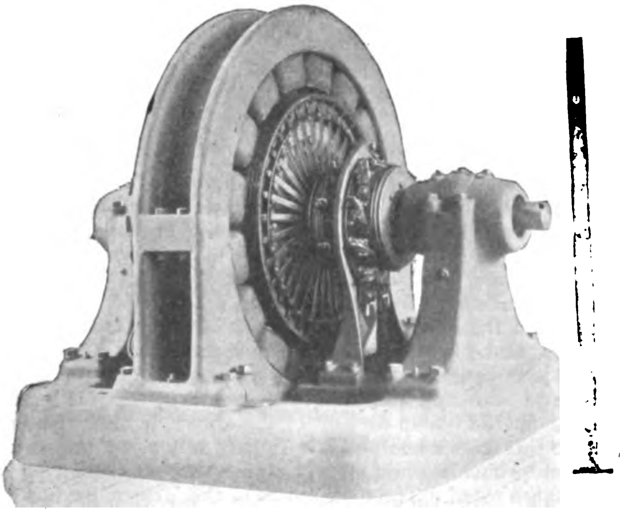

FIG. 1.—G. E. 60 CYCLE ROTARY CONVERTER.

Another valuable feature in this machine is the design of the brush holder studs and the method of attaching them to the yoke. The former instead of passing through insulating bushings in the yoke—as has been customary in this type of machine—is provided with a lug bored to fit down upon a radial stud held by bolts passing through the insulating bushings. To slide the brush holder stud off, it is simply necessary to loosen the nuts on the bolts passing through the bushings. By employing this method, all labor and expenditure of time usually consumed in removing the insulating bushings and washers from the brush holder yoke to remove the stud are avoided, and the change can be effected in a very few minutes. Fig. 1 shows the two phase side of the converter. Upon the collector rings press numerous leaf brushes, having a long contact on the rings, and a very large current carrying capacity.

To obtain the necessary variation in the continuous current of the rotary converter the General Electric Company have furnished with it two special 60-cycle transformers each of 220 k. w. capacity (Fig. 2.) These have been designed to operate with a primary potential of 2,000 volts, and a secondary potential varying from 165 to 220 volts. The variation is obtained through a dial switch over which passes a contact plate cutting out or throwing in, more or less turns of the primary winding and thereby varying the secondary potential. The switch is

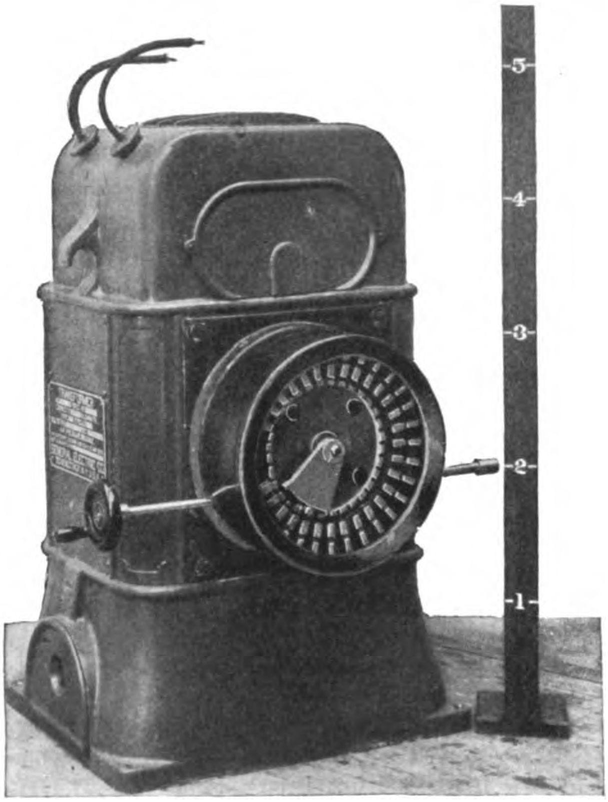

FIG. 2.—G. E. 60 CYCLE TRANSFORMER.

operated by a wheel handle, and the potential may be varied rapidly in either direction, the contact plate snapping from contact to contact in one direction as well as in the other. The dial switch is applied to the transformer itself instead of being a separate device, and the entire construction is singularly compact.

The rotary converter before shipment was subjected to a more than usually severe test. It is now operating satisfactorily in the station, running under heavy loads without sparking or cutting at either the commutator or collector rings.

ELECTRIC HEADLIGHTS. In some of the States the Railroad Commissioners appear to be urging the equipment of locomotives with electric headlights, because "they will save more property and lives each year than all the other safety appliances combined."

FIFE, SCOTLAND. From Fife comes the news that a communistic gin mill makes a yearly profit of £500 in a Fifeshire village of twelve hundred inhabitants. With part of these profits the villagers are equipped with reading and recreation rooms, and they now propose to light the village with electricity and put electric lights in every house at half what it costs.

[Entered as second-class matter at the New York Post Office, April 9, 1888.]

Vol. XXV. NEW YORK, MAY 26, 1898. No. 525.

An Object Lesson for Municipal Plant Advocates.

IT is now about ten years ago that the then Mayor Grant of New York ordered the electric light poles in this city to be hacked down with axes and the wire carted to the city junk yard. This policy of violence was the first step toward the placing of the wires underground, and although no one would now go back to overhead wires the method adopted for bringing about the result will always be considered to have been arbitrary and uncalled for. In striking contrast with the New York ex-Mayor's procedure is the painstaking and intelligent manner in which the officials of Providence, R. I., have gone about adjusting questions of this kind with the local lighting contractors, the Narragansett Electric Lighting Co. The latter company has an exclusive franchise for electric lighting in the city, but instead of abusing its privilege, has steadily increased its hold on the public confidence by its policy of fair dealing, emphasized by a steady reduction in rates. Recently a committee of the City Council was appointed to report upon the placing of high tension wires underground, and the committee's report now lies before us. Before formulating its report the committee undertook a trip of inspection of underground work in various cities, and that it was not a junket is evident from the fact that the committee traveled at its own expense. The proposition which it sanctions for adoption by the City Council is substantially that submitted by the electric lighting company. This contract provides for the gradual removal within three years of all the overhead wires and their placing in underground conduits within what is termed the first building district of the city. At the same time the lighting company agrees to a gradual reduction of the price for lighting from 35 cents to 30 cents, to take effect in 1903, for 2,000 c. p. arc lights burning 4,000 hours per year. Considering the expense which the burying of the wires will entail the rate just quoted will be conceded to be eminently low—one, indeed, that will require the highest economy in all departments of station work. But President Perry, of the Narragansett Co., has always had a reputation for wanting the best that money can procure, and we doubt not that under his management the company will, as heretofore, remain among the most substantial electric lighting properties in the country. At the same time we must express our gratification in these days of municipal ownership agitation that the City Council of Providence has among its members men who are sufficiently intelligent and patriotic to weigh and determine the questions submitted to them in a spirit of fairness to the interests both of their constituents and of their lighting contractors. We feel certain that if every city in the Union had adopted the arrangement entered into by the city of Providence and the Narragansett Electric Lighting Co., by which the latter is limited to a profit of 8 per cent. on its share capital, in lieu of the grant to it of an exclusive franchise, very little would be now heard of municipal ownership of electric lighting plants in this country.

Motormen and Car Control.

THE electric railway has stood during its brief existence of ten years, more than its just share of public abuse and denunciation. At first it was the unsightly and deadly trolley, then the inadequate and offensive storage battery, and now we hear the cry against the poor design or management of the controller. This phase of the subject and the injury done to the public was recently discussed editorially in the New York "Herald." After crediting the cable cars with a slight improvement in their starting and stopping, the article continues:

"But the electric cars have now taken up the running, and they surpass the wildest vagaries of their cable prototypes. Their motormen are not satisfied with one violent jerk. They give us two and sometimes three as they start. Between the step of the car and the seat on which the exhausted passenger is finally flung there is no safety or refuge. Men and women are tossed into each other's arms and laps with constant injury to clothes, to the human frame in general, and to the nervous system in particular. The journey from the Post Office to Harlem is rather more dangerous than if the Spaniards lay in wait for the travelers. Whether these systematic jerks are due in part to an imperfect equipment or wholly to the unskilfulness of the motormen they are equally dangerous and disagreeable. It is quite time for the company to say whether they propose to give us a better service."

To say that the above criticism is uncalled for would be inconsistent with facts, for it is true that the sudden jerks in stopping and starting the cars are altogether too frequent and extremely annoying. It only remains to fix the blame and suggest remedies for this public nuisance. To the electrical engineer who has carefully watched the gradual development of the electric car and the labor, money and care which has been expended on each detail, nothing would seem as absurd as to place the blame of the nuisance on the electrical or mechanical equipment. The body of the car itself is a model of mechanical skill, well balanced and proportioned. The truck has received careful attention from well known engineers, car wheels and track construction have been brought well nigh to perfection, and much care has been bestowed on the braking mechanism. The electric motor has gone through many stages of development, until now it has reached a point of perfection seldom attained in machinery as heavy and as much tried. Motor suspension and the driving mechanism have been carefully studied problems, and the methods of suspension used at present, as well as the single reduction method of connection make it possible to start and stop a car without a jar or jolt. Having failed to fix the blame on any of the above, it only remains to examine into two more possible causes, which, by the way, are the most probable ones namely, the speed controller and the motorman himself. The mechanism of the former, having reference to the series parallel controller, which is the one in use on the roads in question, has been specially designed with a view of insuring perfect flexibility of operation. The motors, which are connected in series when the car is at rest, are gradually by nine successive steps changed to a parallel connection, by which time the car has attained its maximum acceleration by apparently insensible gradations. Each step in the transaction has its specific purpose, and it is the neglect of the motorman to allow the full effect of each step to exert itself, which causes the disagreeable and avoidable shock to the passengers. This is due either to the lack of training of the motorman or his endeavor to make schedule time. The same causes are responsible for a city electric road requiring from 15 to 25 per cent. more energy to operate it than would be required were all the motor-

men to handle their controllers carefully and intelligently, with a view to using as little current as possible without getting behind time. The efficiency of the series combination at the start is totally destroyed by the rapid turning on of the power, and the armatures are overloaded by cutting in the field shunts too soon. One remedy for this has already been suggested by Mr. J. R. Cravath, in the use of his "excessive current recorder," described in The Electrical Engineer, January 20, 1898, which is designed to furnish an electric railway management with the knowledge of the excessive use of current by various motormen without interfering with the operation of the road. While thus insuring the management against an uneconomical use of the current, the public is equally benefited by the correct use of the controller. But it appears as if simpler remedies than the above could be devised, namely, the correct training of motormen and the fixing of a schedule which permits the men to use the necessary care and discretion in the starting and stopping of the cars.

Cutting the Manila Cable.

OUR recent remarks on the importance of having competent marine electricians on board a fleet that is likely to have cable cutting to do or wants to use cables after they are cut, find confirmation in the reports that arrive from the Philippine Islands. Just what the rights of the cable companies are, nobody knows exactly, despite the rules and regulations that have been drawn up and recognized as a code. But whatever those rights may be, it is certain that in time of war, a country like the United States would not allow a cable to be long used as a means of offence or attack against it, and that is just what happened at Manila, when the Spaniards, controlling a cable owned by neutrals, would not allow our fleet access to it. We thereupon cut the cable, doing just the right thing; but as our fleet had no operators and the Spaniards would not permit the use of any from the island or of apparatus, there was a deadlock, which nothing can relieve until this country is as fully master ashore as it is afloat, in the Philippines. In this connection we may quote the comments of the London "Electrical Review": "In any case, the importance, from a practical point of view, of equipping every war vessel with the simple apparatus necessary for establishing communication through a cable, when need be, is more than evident. With the old marine galvanometer no readable signals could be obtained, but the Sullivan galvanometer, now used in our Navy, is adapted for both testing and signalling purposes, and with but a little practice, naval men should become expert in exchanging messages through cables, whenever the occasion may arise. We believe our war ships now have the means for grappling cables in shallow or moderate depths of water, as well as suitable electrical apparatus."

If this be the case, our own ships should be similarly equipped, and the need in Cuban waters to-day for good marine electricians is as great as in the Far East. This is one of the things that must be seen to.

The Advisability of Frequent Reinspection.

THE recent fire at the Union League Club, Chicago, caused by the crossing of electric light and annunciator wires and the deterioration of the insulation of both wires by moisture, is to be sincerely regretted, and is another reminder of the absolute necessity of frequent inspection and reinspection of electric installations. It would certainly seem as if the new "National Code," which is the result of the united efforts of the various electrical, insurance, architectural and allied interests, would be a safeguard against such calamities, if the rules and requirements laid down therein were closely followed by the companies installing electrical apparatus, and were enforced by the boards of fire underwriters and inspectors.

In view of the danger involved and the severe punishment imposed for the violation of these rules, we may without reserve express the opinion that the regulations are generally adhered to and that the frequent fires are caused by the superficial and uninspected work done, or repairs made after an installation has been completed. This, as well as the destruction of the insulation of wires due to abrasion or other mechanical injury or the disastrous effect of the slightest presence of moisture, at once suggest the necessity of frequent reinspection of electrical installations. One need not seek far in our own city for reckless examples of provisional wiring, installed by men who apparently did not fear or expect a reinspection of the installation. It would be well for the Board of Fire Underwriters to look into this matter and appoint a staff of reinspection, whose duty it shall be to see that no new wiring of whatever nature is installed anywhere unless it conforms in every particular with the rules and regulations contained in the "National Electrical Code." Such measures as are now in force appear inadequate.

The Electric Railway Controller and Motor Suspension Decisions.

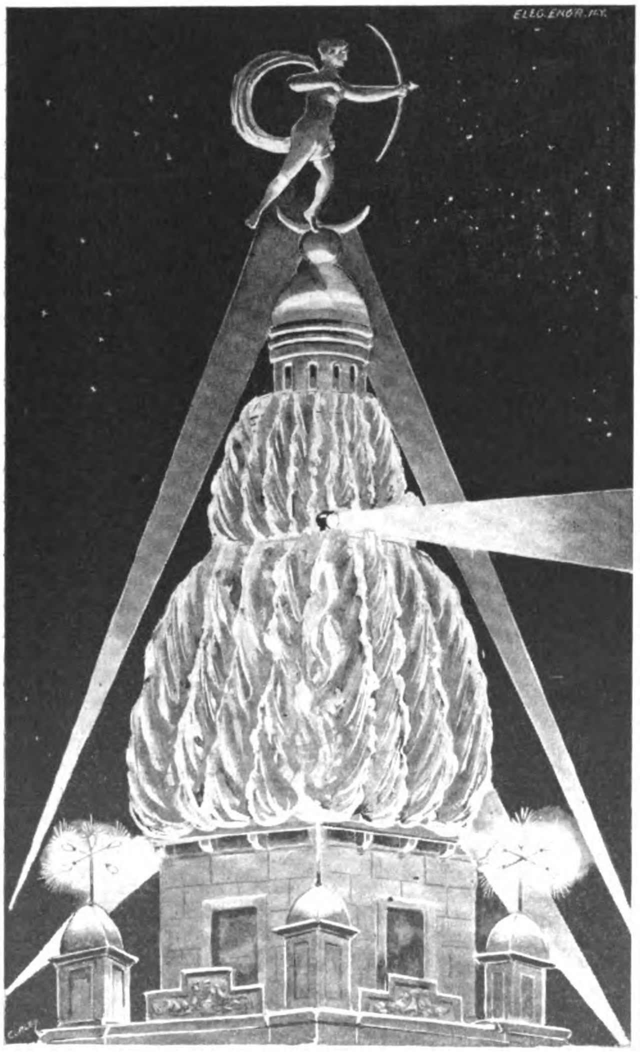
LAST week we announced that the Edison compound winding patent had been declared void by the courts, and called attention to the fact that this was another of the series of so-called controlling patents which had gone the way of everything earthly. But that conclusions ought not to be drawn too hastily as to the true value of existing patents in the art is manifest from two decisions just rendered which promise to have an important effect upon the electric railway industries. One of them sustains the broad claims upon the series parallel controller, and the other sustains claims covering the spring suspension of motors centered upon and geared to the car axles.

The two fundamentals of electric car propulsion are the electric motors and the electric controllers. Practical development has discarded all methods of control other than that known as the "series parallel." This involves, however, something further than the mere idea of coupling the motors in series when starting and in parallel when running at full speed. That suggestion entered early into the field, but was abandoned for the difficulties attendant upon the heavy electrical discharges and inertias of current which accompanied a change from one relation of circuits to the other were so great as to be regarded as insurmountable. The wasteful rheostatic method, therefore, remained in use until Mr. Condict, working in the storage battery fields of traction, came forward with his solution of the difficulties. His plan involved the use of "dead" resistances which could be introduced gradually into the circuit before a change in the circuit connections from series to parallel or from parallel to series and are then gradually cut out of circuit. There are thus two uses of the dead resistances; first, the protecting use at the time of shifting the circuit connections, and, second, the temporary use of supplementary resistances at times when it is not necessary to make changes in the circuit-connections, but it is desired to obtain minor gradations of speed. When it is considered that this method of control has superseded all others, that it is regarded as absolutely essential, and that every modern electric car controller is now built upon this principle, the rendering of Judge Townsend's decision awarding the merit of its discovery to Mr. Condict is a compliment of which any inventor might be justly proud.

The decision of the Circuit Court of Appeals on the spring suspension of electric motors is another important factor in the future of electric railroading. All manufacturers of electric railway motors have thus far found it necessary to flexibly support one end of the motor and to sleeve the other end upon the axle of the car. This was as true of the old double reduction motors as it is of the present single reduction motor. Thus far at least no other way of supporting motors appears to have been found practical. Although the effect of these two decisions may be somewhat severe, it must nevertheless be encouraging to the developers of electrical arts to know that it is possible to sustain good patents. As the patent laws are primarily designed to encourage invention, it is a matter for congratulation whenever an original inventor has the satisfaction of having his patent sustained.

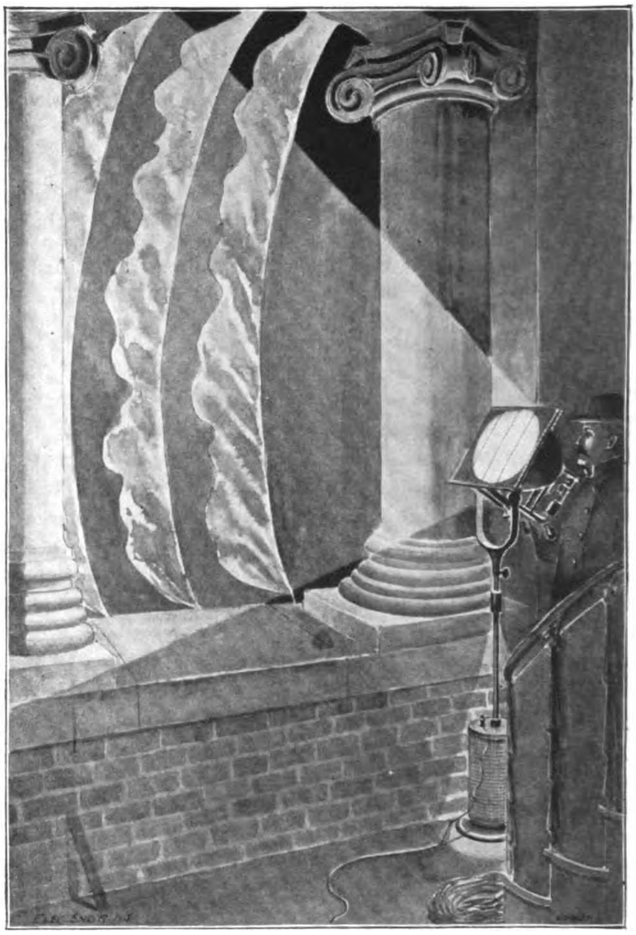
The Lighting of the Madison Square Tower.

FAR reaching as the educational and commercial influence of the second Electrical Exhibition is, and lasting as the impression will be which it has made on the minds of those who have seen its numerous magnificent displays and special features, the illumination of the tower of Madison Square Garden will probably be longer remembered by the citizens of Greater New York as a whole. Never in the history of the Garden has its exterior presented so gorgeous an appearance as it has during this time. The tower, which is in itself a model of architectural design, has for this occasion been so enhanced by means of electrical light effects, that it has become one of the features of New York at night. The goddess Diana, heretofore hidden from view after sunset, now becomes visible at night. The effect produced by the multi-colored beams from fourteen searchlights behind a mass of very thin white silk gauze is beyond description, and unless our readers are fortunate enough to see the beautiful display, we again refer them to an account published in the "Evening Post," and reprinted in our issue of May 12. This short sketch, however, left the reader without a knowledge of the means employed to produce these effects, and a few of the technical details will certainly be of interest.



THE TOWER OF MADISON SQUARE GARDEN, SHOWING ELECTRICAL DECORATIONS.

The upper three tiers of the tower, which is shown in the illustrations, were covered with about 2,000 yards of very thin, silky material, of the same nature as that used by Loie Fuller in her celebrated skirt dance. The gauze is fastened to the tower, from tier to tier, in vertical columns, each one yard in width, the halyards on which they are mounted being loosely strung between the columns supporting the tier above. Surrounding the lower tier, which is 30 feet in height, there are thirty of these strips; around the middle tier, which is 25 feet high, there are twenty-four strips, and eighteen of them surround the upper tier, which is 15 feet in height. Behind this mass of delicate gauze, which stands out in graceful undulating curves when swayed by the wind, are placed eight Ziegler stage lamps with colored screens, the color for each tier being different. These lamps, which are in charge of stage lighting experts, are specially well adapted for this work, on account of the right angled arrangement of the carbons. The reason for this is obvious, for it is well known that the light is projected from the positive carbon, which in this case points directly at the object to be illuminated. These lamps throw their light directly behind the gauze, while six more similar lamps stationed on the parapet below add to the effect by throwing their colored rays obliquely against the lower folds of the fluttering material. The current is led up to the tower by three large feeders of the Edison three-wire system, and when all the lights are in operation a current of about 300 amperes is used. It is said that the radiant effect is clearly visible at a distance of many miles from New York city in every direction.



THROWING COLORED PROJECTION BEAM ON DRAPERY FROM WITHIN THE TOWER.

WAR NEWS.—The announcement of news from the seat of war which has now become a regular feature of the Show is being highly appreciated by the large number of visitors. The bulletins are thrown on a large screen in the Main Hall and Concert Hall as soon as they are received from the most authentic sources.

General Notes of the Exhibition.

The past week at the Electrical Exhibition has been marked by a steady maintenance of the popular interest. In fact, it has been surprising to see how large the crowds are on wet nights, which unfortunately have been much more numerous than the fine ones. On fine evenings the Show is sure to be thronged in every quarter, and the utmost interest is taken in every feature, whether of mere novelty or for educational purposes. The Moore Chapel has always its long waiting line, the crowds around the wax tableaux are often five and six deep; the explosion of mines in the tank draws without fail, while all the other fifty features are constant centres of attraction.

During the past week an exhibit of unusual interest was added in the Assembly Rooms, adjoining the other relics and curios. It has been loaned by Mr. Daniel Davis, of Phillipsburg, N. J., and embodies some of the work of his modest but talented father, such as the very rare book that he wrote on electricity and magnetism. The chief features of this special exhibit are the early examples of electro-deposition in gold and copper. One of these is of a little child's arm, taken fifty years ago, and probably the very first instance of electroplating the human body. There are also examples of japonica leaves, buds, etc., and a portrait in electro-deposition of Daniel Davis himself. One very interesting exhibit is that of a gold medal awarded in 1847 to him for his electrical instruments by the Massachusetts Charitable Mechanics' Association. Being "hard up" and really in need of food, as the result of his zeal in experimenting, he took casts of the medal, used the medal itself for plating the two shells, filled the inside with wax, and preserved this electrotype, meantime using the real medal, which he melted down, as a means of providing bread and further resources for investigation.

During the present week all the regular features of the Exhibition will be maintained in full swing. On Thursday an important lecture will be delivered in the Concert Hall before the New York Electrical Society by Prof. S. H. Short. This well known engineer will speak on "Heavy Electric Traction," and the lecture will be illustrated by lantern slides and the projectoscope. The following night, the Society will celebrate its recent work and the election of its new officers by a dinner at the St. Denis Hotel, Broadway, at 7:30 p. m.

The influx of children to the Show during the past fortnight has been very notable, and is an excellent thing, both for the Exhibition and for the rising generation.

Exhibit of the Edison Electric Illuminating Company.

THE exhibit of the Edison Electric Illuminating Co., of New York, occupies, in three sections, the first of the larger spaces on the main floor, containing about 800 square feet to the right of the main entrance. Within a spacious and highly artistic Grecian temple, surmounted by a dome brilliantly illuminated by 4,000 miniature incandescent lamps, are shown the more important and novel applications of electricity to industrial and household purposes. In the central section, beneath the dome, which is devoted to electric lighting, are shown miniature and candelabra lamps, ranging from 1 to 8 c. p.; standard lamps from 8 to 100 c. p.; reflected ceiling lighting, the lamps being concealed from view; the new English reflector lamps, which will soon be introduced into this country; sign lighting and advertising designs, as shown by the lettering around the upper portion of the temple; artistic decoration and variation effects illustrated by the beautifully lighted dome. In arc lighting are shown enclosed arc lamps of the Bergmann, General Electric, MacIntire, Pioneer, Ajax, Bijou, and Standard types, ranging from 400 to 2,000 c. p., and burning continuously with one trimming of carbons, from 100 to 150 hours; Colt projectors, for photographic and stage purposes, throwing varied colored beams of light around the exhibition hall. Under supported lamps, feeding from below, very suitable for post and doorway lighting, are also shown. Very artistic MacIntire post lamps guard the entrances to the booth. A Thomson meter is connected to a bank of lamps and the attendants take special pride in showing how this splendidly balanced instrument registers accurately the current consumed by one single lamp. There is also exhibited a box containing several sections of feeders such as are laid down by the company in the streets of New York.

The end section of the exhibit, nearest the entrance, is devoted entirely to electric heating and cooking, the numerous devices being in actual operation. There are shown in this space the cooking devices manufactured by the American Electric Heating Corporation, such as electric ovens, chafing dishes, farina boilers, tea kettles, coffee pots, egg boilers, heating coils, coffee and hot water urns, as well as irons for boudoir as well as heavy tailoring work, soldering irons, an apparatus for vulcanizing patches on bicycle tires, curling irons, foot warmers and radiators. A picture of the Edison Co.'s celebrated electric kitchen is also shown. This kitchen has in its entirety been transported lately to Sandy Hook, where it is supplying the electrical corps with food far daintier and certainly better prepared than the rations dealt out to other defenders of our coasts and harbors.

The third section of this magnificent exhibit is devoted to power, largely "direct connected." Here are shown a printing press direct connected by friction pulleys to a G. E. motor; and a rotary printing press driven by a Crocker-Wheeler slow speed motor placed under the table carrying the press. This press prints, cuts and delivers 36,000 to 60,000 copies an hour. There are also a Morrison direct connected book binder; a drill press with Crocker-Wheeler motor; an ironclad motor connected by means of a long flexible shaft to a drill press; a Lundell motor

THE NEW YORK EDISON CO.'S EXHIBIT.

direct connected to a Quimby rotary pump, controlled by a Zimdars & Hunt switch; Singer sewing machines driven by self-contained Diehl motors; and a stereotyping outfit for meteorological work. A new refrigerating plant, built by the Hygienic Refrigerating Co., operated by a C & C motor, shows the actual freezing of water and does work equivalent to the making of 500 pounds of ice per day at a cost not exceeding the prevailing price of ice. Besides these exhibits at the booth, this company, which is by far the largest and most successful electricity supply company in the world, has placed around the main hall several arc lamp posts such as they have installed in several New York streets and avenues. They also supply current for the lighting of the building and that used for the vacuum tube lighting in Moore's Chapel.

A description of this enterprising company's exhibit would be incomplete without the mention of the following entertaining and instructive features which have made this booth a Mecca for the visitors of the Show. All cooking apparatus is in working order, and tea and biscuits are freely served to all by Mrs. Helen Hyde and her numerous assistants. The printing presses are at work turning out war dispatches received in the company's booth by special telephone arrangements. A beautiful self-playing piano is sending out its melodious strains and invites all to come hither and partake of the hospitality of the Edison Company, ably represented by such well known engineers as Messrs. Arthur Williams, John van Vleck and J. W. Lieb, Jr., assisted by Messrs. W. D. White, D. Burnett, C. A. Littlefield, H. D. Betts, and W. D. Brown. The entire exhibit was authorized by Vice-President R. R. Bowker before his departure for Europe, and reflects great credit on all who have shared in the carrying out of the project.

The Bullock Electric Mfg. Co.'s Exhibit.

THE Bullock Electric Manufacturing Company, occupying an attractive booth on the right hand side of the centre aisle, have one of the first exhibits noticeable upon entering the hall. The display consists of one 25 k. w., 125 volt slow speed direct driven generator; one 25 k. w., 125 volt moderate speed belted generator; one 7½ h. p. moderate speed open motor, and one 10 h. p. slow speed enclosed motor.

The direct driven generator is receiving unusual attention. The perfect symmetry, finished details and compactness of form attract the eye, and the many peculiar points of construction hold the attention for deeper investigation.

Of the various claims of the company for the apparatus here shown may be mentioned the extreme stiffness of field obtained by an original construction of the field poles. These field poles are built of very thin laminations of soft iron, in such a way that the pole face contains but one-half as much iron as the pole proper. By this means a strong density is obtained where the lines of force enter the armature, accomplishing the same result as would a wide and dense air gap, with a considerable saving in current required for excitation. By virtue of this stiff field, field distortion is reduced to a minimum. The thin laminations completely break up eddy currents. By thus ridding the fields of the choking action of these eddy currents when the compound coil is producing this effect an extremely quick acting field is obtained. The field coils are separated, allowing perfect ventilation, and being wound upon separate forms, are readily removable.

The enclosed motor represents the latest practice in this kind of machinery. It is thoroughly protected from dirt and water, and is so constructed that by removing the small cover the commutator may be inspected.

Mounted upon a board in the rear of the booth is one of the company's type "T" controllers wired to this motor. Although this controller is remarkably small, it permits six different speeds in forward or reverse direction, and also operates an electric brake, by means of which the motor can be brought to immediate rest, from full speed. With this controller the armature can be moved inch by inch—a valuable point when running certain kinds of machinery. The Bullock exhibit is noticeable for its neat arrangement, and the prominence which is given to the essential features of the machinery. It should be added that the John Thomson platen press used on the opening night, and since then doing splendid work with fine half tones, in circulars for distribution, is operated by a direct connected Bullock motor.

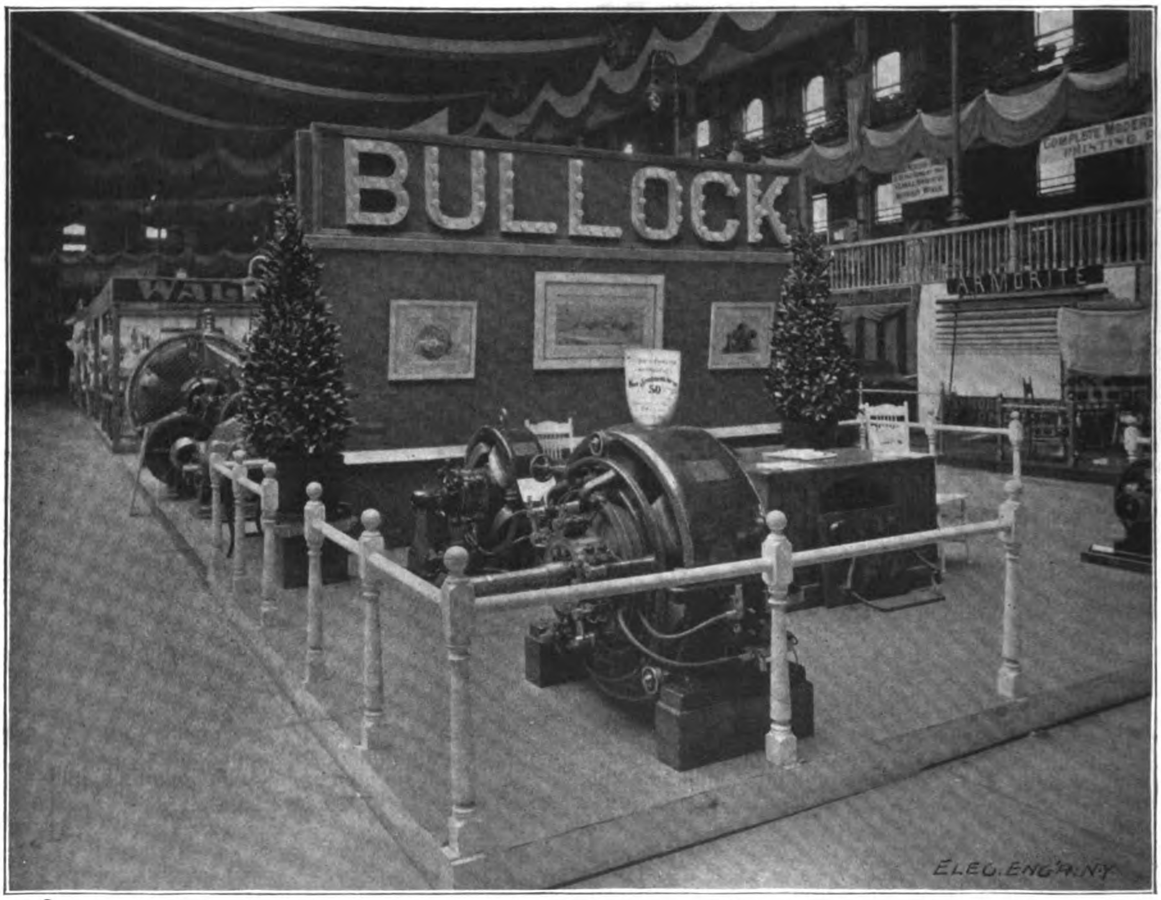


EXHIBIT OF THE BULLOCK ELEC. MFG. CO., MAIN FLOOR.

The Pope Mfg. Company's Columbia Electric Carriage Exhibit.

ONE of the most striking indications of the rapid advance taking place in electrical engineering is the development of the electric automobile road carriage. The Electrical Exhibition at Madison Square Garden, New York City, offers a very strong illustration of the fact. The opportunity to observe this new branch of electrical transportation is an exceptional one.

In the exhibit of the Pope Manufacturing Company, what is probably the very latest development in this branch of electrical engineering is shown in the form of a "Columbia Carriage Mark IV," as it is termed. This vehicle consists of a very elegant appearing double-seated road carriage. It is large enough to carry four people very comfortably, and six people without discomfort. The illustration given shows the general style of vehicle.

Its electrical equipment consists of 42 cells of storage battery capable of very high discharge rates, and the general abuse that traction batteries are called upon to stand. A novel feature of these batteries is the fact that there are three positive plates and two negative plates in each cell. The positive plates are of a Planté formation and are made extremely porous, so that a certain amount of the active material on the outside surface is available. The 42 cells are arranged in six similar boxes, seven cells being sealed in each box. The total weight of the battery is

1,500 pounds, and its capacity at a 40 ampere rate of discharge is 120 ampere hours. This is sufficient to drive the completed carriage with five occupants thirty miles on fair roads, and more on good roads, at an average speed of ten miles per hour. The vehicle complete, ready for service, weighs 3,000 pounds.

While the exhaustive tests that the Pope Manufacturing Company carried out before their selection of a storage battery indicated that a much lighter battery could be produced which would give the same work as the one in the carriage, yet no such battery would be practicable in the hard, every-day service in which these carriages are intended to operate. It is claimed to have been the aim in the designing of the electrical equipment for this vehicle to strike a conservative compromise between a commercially practicable length of life and the least possible weight. From the figures given, it certainly seems that this compromise has been judiciously taken.

The carriage is fitted with a specially designed controller for the duty in hand, which groups the six boxes of batteries in three different groups, giving three different voltages. The motors are wound and the gearing arranged so that these different voltages give the following speeds: 2¾, 5½, and 11 miles per hour. The operation of the controller is, of course, very

HORSELESS CARRIAGE EXHIBIT OF THE POPE MFG. CO.

similar to that on an electric street car, except that it is much more convenient to the operator, enabling him to give his principal attention to the guiding or steering of the vehicle. The controller is operated by a fore and aft moving lever grasped by the left hand. The notches are very distinctly felt, and the question of speed control seems to be perfectly met in every particular.

The principal feature that strikes the electrical railroad engineer in the motor equipment is the similarity between it and the approved street railway construction, except in the matter of motor suspension. No spring is provided. The motors are rigidly fast to the running gear of the vehicle and geared to the driving wheels through single reduction gearing. The makers of the carriage have found that with the pneumatic tires which they use there is no necessity for a spring suspended motor. The tires annul all the shocks from the road, and as is evident by the condition of the commutator in a carriage which has been operated continuously for over a thousand miles, the controller seems to provide for the shocks of starting.

Unlike a street car, however, it is necessary on a road carriage which is fitted with rubber tires to provide for the outside wheel turning faster than the inside wheel when turning corners. This is accomplished very happily by the providing of two motors, one for each driving wheel. The difficulty of overloading the motor driving the inside wheel is overcome very ingeniously by so arranging the connections that the armatures are always in series. In some cases where particular graduations of speed are required, the motor fields are coupled in numerous combinations of series and parallel, but the armatures are invariably in series. This, of course, solves the problem of turning corners, as far as overloading the armatures goes. The carriage is enabled to start from a standstill in a very muddy road with the steering wheels cramped to their maximum without any difficulty being experienced in current consumption or sparking at the commutators.

The Pope Manufacturing Company reports that one of the most difficult problems in the development of the electrical road carriage for popular use was getting a battery which would stand the abuse that the untechnical public seem unable to avoid occasioning. The principal abuse is what is called "starving" the batteries, or not putting back into them as much current as has been taken out.

To overcome this, an ingenious system of electrical measurement has been developed. It consists principally in a specially designed recording wattmeter. The current passing out of the batteries and into the motors when running the carriage passes through this wattmeter and causes it to register accurately in watt hours. When the carriage battery is re-charged, the connections are such that this wattmeter runs in a backward direction, or as it may be termed, returns toward the "Full" position. It runs, however, at a slower rate when the batteries are being re-charged and therefore does not arrive back at the full position until a certain excess in ampere hours over what was taken out has been returned to the batteries. This excess, of course, provides for the losses occurring in the battery. The meter is, furthermore, provided with a small cut-out device so that when the recording finger reaches the position known as "Full," the main switch of the carriage is automatically thrown, thus cutting out the charging current. The purchaser thus has the charging of the batteries taken entirely out of his hands. When he makes the necessary connections through a regular charging plug and cable that are furnished with the carriages and closes his charging switch, there is absolutely nothing more for him to do until the batteries are full.

"Starving" the batteries is thus very successfully avoided and all of the numerous troubles following upon failure to immediately re-charge after a long, severe discharge are overcome. The excess returned to the batteries is enough to provide for the necessary de-sulphating and losses that take place from slight and unavoidable inter-cell leakage.

Another interesting feature from an electrical standpoint in these vehicles is what is termed the "running plug." It consists of a small aluminum, specially shaped plug which is inserted in the main circuit which is led up to the seat convenient to the left hand of the operator. The removal of this plug prevents the carriage from being started, and also provides an immediate switch in the event of the remote possibility of anything happening to the controller preventing it being returned to the "Stopped" position.

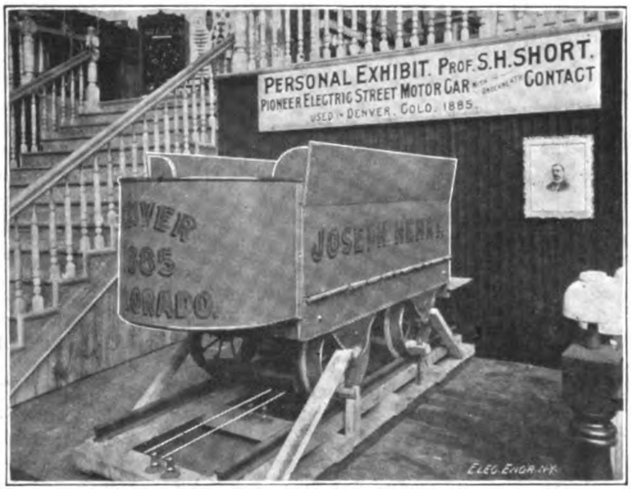
The brake is a most powerful one and consists of two metallic bands surrounding pulleys arranged on the armature shaft. A very light application upon the foot-pad exerts a very strong retarding effect. An emergency brake is also provided which applies shoes directly to the tires of the driving wheels. A lever actuating this brake extends up outside of the carriage, also convenient to the left hand. Incandescent electric lights are provided which give an illumination for night running, of course, far superior to any other form, and adds its share in making these vehicles truly representative of the period. All of the mechanical parts are entirely housed so that no moving parts are seen when the vehicle is running, other than the wheels. This gives a very simple effect in favorable contrast to the average motor carriage of the past. The finish of the carriage is one of its most striking features. In every particular it is essentially up to the standard of the most elegant equipages in use to-day.

Prof. S. H. Short's Personal Exhibit—The Denver Car.

FEW exhibits at Madison Square Garden can compare in interest and importance with that which has been kindly loaned by Prof. S. H. Short, namely, his quaint pioneer car used in Denver as long ago as 1885. This car has been placed near the exhibit of the Walker Co. (of which Prof. Short is the electrical engineer) on the main floor; while just across the hall is the regular type of New York Metropolitan car, operating upon a stretch of the latest type of Walker conduit. What a significant history of tremendous development lies between these two extremes!

The Denver car was built while Mr. Short was Professor of Physics in the University of Denver, and it is shown running on underground conductors. Prof. Short was a firm believer

even in those early days, in underground methods, and had a track three or four hundred feet long laid in the University grounds, over which this car, the "Joseph Henry," operated, a company called the Denver Electric & Cable Company being formed to do this, and also to build longer lines, until at last several miles were equipped and operated, with three regular cars in service. At that time, Prof. Short made a resolute effort to employ the series system in the transmission of the current, and the operation of the various lines; and he pursued his purpose with characteristic and laudable tenacity until he had thoroughly satisfied himself and the electrical public at large, that electrical roads must be operated on the multiple arc method. This exhaustive work of Prof. Short was a service to the art, the value of which cannot be overestimated,



THE "JOSEPH HENRY" DENVER CAR OF 1885.

and should be as fully counted to his credit as a bold pioneer as any of the earlier or later successes that he has made.

The car at the Exhibition is well preserved, and with its bright yellow paint catches the eye at once. Underneath it are shown the contact wires, over which the collecting bars or contact brushes ran—for Prof. Short was indefatigable in the means that he tried, and the same struggle was necessary as was required to work out practical forms of overhead trolleys. As a matter of fact, Prof. Short, then quite a young man, experimented with about all the devices that are feasible, and had slotted conduit tubes, shallow conduits, sectional conduits, circuit closers, conduits of the cable type, lights in the cars from the railroad circuits, electric gongs, single reduction motors, and a variety of other features, many of which are now so thoroughly embodied in the art that it would be difficult to reconstruct the art without them. It must be considered fortunate that the Exhibition includes so interesting a memento as this famous pioneer car.

The Exhibit of the Electric Storage Battery Co.

THE Electric Storage Battery Company's 50 foot sign at the eastern end of the building is one of the first features that attracts attention upon entering the Garden. Just below this sign there is mounted a row of large glass jars, each one carrying one letter of the words, "Chloride Accumulator," the well known trade-mark of the Company. Dummy lugs are used for connecting the jars together, and they present the appearance of a fully equipped battery. When illuminated from within, as it is each night, the sign presents a particularly attractive and novel appearance.

A novel use of battery plates is also shown in the sign which extends along the rear wall of the space. Twenty-seven plates of type G are exhibited, each plate showing, in unformed lead, one letter of the Company's name, the portion of the plate around the latter being peroxodized.

The operation of the chloride accumulator in a number of important applications is demonstrated. At the rear of the space, and mounted upon a handsomely finished stand, is a battery of sixty chloride accumulators of type F-11. This battery supplies power for operating the scores of motors, the sizes ranging from the smallest to the largest, in the adjoining space occupied by the Sprague Electric Co. As these motors are constantly being thrown on and off, the load on the battery is a varying one, having fluctuations of from 0 to 250 amp. The battery, connected across the line and charged from a constant source of supply, operates as a regulator of potential, the voltmeter needle remaining absolutely constant under the variations in load stated above. This application is a very interesting one as demonstrating the use of chloride accumulators in connection with electric elevators and on trolley lines.

Near the front of the exhibit are two large central station cells. One containing 27 plates 15½x32, is placarded as being the largest central station cell in operation at the time of the last Electrical Exhibition in New York, in May, 1896. The adjoining cell is from the largest storage battery in the world, and is one of the 166 cells which are being installed for the Chicago Edison Co. The front of the cell is cut away, permitting a very interesting view of the method of construction and plate suspension. The tank is 76⅜ inches long x 40½ inches high x 21½ inches wide, and contains 83 plates, each 15½x32 inches.

At the other end of the exhibit is a 25 foot electric launch of the most modern type built by the Electric Launch Co. at Morris Heights, N. Y., and equipped with chloride accumulators

EXHIBIT OF THE ELECTRIC STORAGE BATTERY CO., MAIN FLOOR.

A chloride accumulator for welding work is also shown. This outfit consists of one cell of type F-11 with a normal discharge of 50 amp. connected by heavy cables to copper clamps, by which the metal to be welded is gripped. In the welding

operations that are being shown, the cell discharges at rates ranging from 400 amps. to 1,000 amps.

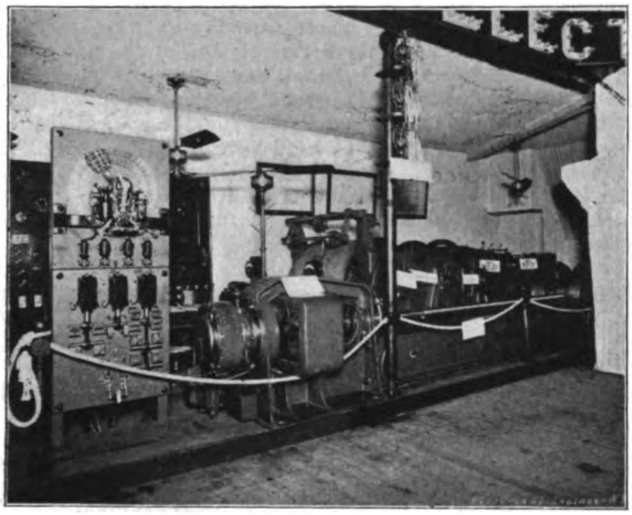
Chloride accumulators in portable form are shown operating phonographs, spark coils, fan motors, lamps, etc., and are also in use by a number of other exhibitors who have appliances calling for small powers.

The Battery Co. distributes a very neat folding foot rule, which is much appreciated by the recipients.

The exhibit is in charge of Mr. Chas. Blizard, manager of the Company's New York office, and Messrs. Albert Taylor, T. B. Entz, G. A. Robertson, W. H. Palmer and Carroll Hodge, all of whom are most courteous in their attentions to the countless visitors making all kinds of inquiries and asking all kinds of questions.

The Sprague Electric Co.

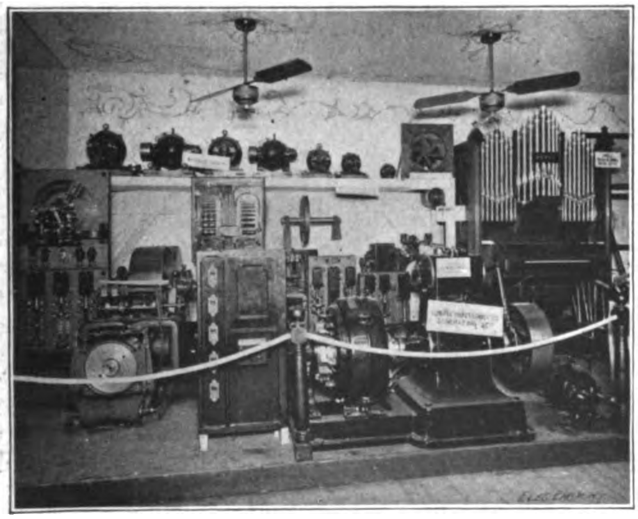
THE exhibit of the Sprague Electric Company at Madison Square Exposition is a remarkably fine one and quite characteristic of the Company. It is located at the east end of



SECTION OF THE SPRAGUE ELECTRIC CO.'S EXHIBIT. MAIN FLOOR.

the Garden, and occupies a space of considerable depth and 65 feet in width, illuminated by a very large and striking electrical sign. Although the space is large it is completely filled with exhibits of the various products of the Sprague Company.

Chief among these, perhaps, and in the foreground, is the



SECTION OF THE SPRAGUE ELECTRIC CO.'S EXHIBIT, MAIN FLOOR.

electric elevator exhibit. Therein are shown types of machines all the way from an ammunition hoist up to the now famous multiple-sheave and ball-nut machine in use in so many of the high office buildings in this country. Another notable elevator exhibit is a machine known as type "S," forty-nine of which are soon to be installed in London, England, for the underground railway of that metropolis. This type of machine is said to be the largest ever manufactured.

The Sprague exhibit seems to have been happily designed to excite popular interest, and the organ, almost continuously in operation, by means of a Lundell blowing outfit, and the dainty little house elevator machine always at the service of visitors, for operation, have caused the Sprague exhibit to be the constant centre of an interested throng. There are, of course, Lundell fan motors, power motors, dynamos, direct-connected generating sets, brass and iron armored conduit, and all the other specialties which have made possible the enormous business of the Sprague Company. Printers are a good deal interested in a two-revolution four-roller press, which is in operation, driven by a direct-connected slow speed Lundell motor.

All told, the Sprague exhibit is a striking feature of a striking show.

J. Jones & Son's Exhibit.

THE magnificent exhibit of Messrs. J. Jones & Son, of 64 Cortlandt street, which is located on the main floor at the right hand side of the Garden, by the first stairway leading to the Promenade, has at all times during the Exhibition been a centre of attraction by reason of the fine display, tasteful arrangement of the various instruments, extremely courteous treatment extended to all and the novel features frequently shown. At the entrance of the booth is a beautiful figure of the goddess of liberty, dressed by Mrs. E. A. Lowe, wife of the energetic and genial manager of this enterprising house. During the Exhibition all little girls visiting the Garden have been requested to write their name and address upon a card prepared for them and drop it in a slot at Miss Liberty's feet. At the

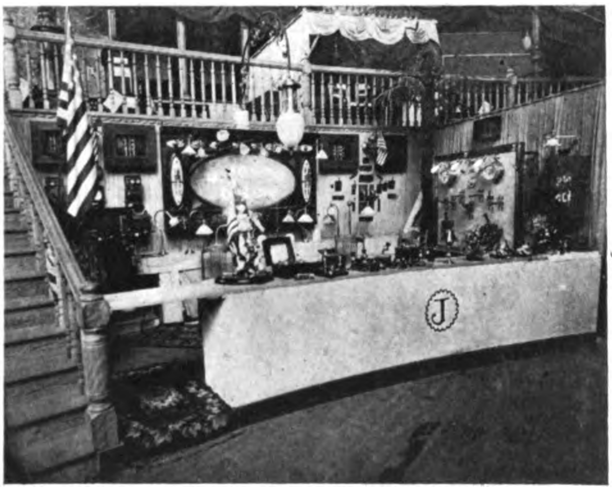


EXHIBIT OF J. JONES & SON, MAIN FLOOR.

close of the Exhibition this box of cards will be well shaken, and one card drawn out, the name of the little girl announced, and Miss Liberty will be sent to her address free, with the compliments of J. Jones & Son. At the back of the booth, which has been handsomely draped, is fixed a display board, the centre of which is a large oval panel, smaller panels running along the top and bottom and the two sides. The top panels are surrounded by various styles and sizes of incandescent lamps. Around the two side panels and the bottom panels are placed single and double pole switches.

In the large central panel, on a blue plush background, the name of "J. Jones & Son" is set in 8 c. p. frosted incandescent lamps. On both sides of this handsome display board are shown panel boards, switches, a new Ward-Leonard circuit breaker, wall telephone sets and an automatic cut-off clock. On the counter in the back of the booth are shown artistic porcelain shades, and at the front of the booth, on a long counter, are displayed numerous articles, such as electric curling irons, sad irons, soldering irons, an electric stove, desk and inter-communicating telephone sets, medical batteries (a specialty of this company), fan motors, etc. At the right of the booth is a handsome switchboard made by the firm. It is fully

equipped with Jones switches, Weston volt and ammeters, and a Cutter circuit breaker.

In the left hand corner of the booth is a large Holtz static electrical machine with a chime of silver bells upon it. This has afforded the visitors infinite amusement by the sweet tone of the bells and the sharp crack of the blue spark, fully eight inches long, which is shown and aptly explained by the attendant as "pure lightning."

Hanging directly over the centre of the booth is a beautiful arc lamps, which has not attracted any particular attention until a few evenings ago, when to the astonishment and amazement of all, the lamp was burning without its outer globe, and the ornamental brass jacket also removed, thus exposing the lamp in its nakedness, and showing decidedly one of the simplest and most effective arc lamps in the market, one for which Mr. Lowe is now perfecting arrangements to give it to the public. Another step of this enterprising manager is the company's recent removal to 64 Cortlandt street, where they occupy the entire building. On the first floor is the salesroom, on the second floor are the offices, the basement is used for shipping, and the upper floors for stock, besides adding space to their already large factory in Brooklyn. This very creditable exhibit is in charge of Mr. W. B. Burtis, who very ably and courteously explains the numerous interesting features.

The Hornsby-Akroyd Oil Engine—Exhibit of the De La Vergne Refrigerating Machine Co.

IN the basement amongst the steam, gas and oil engines, the exhibit that has attracted a great deal of attention is that of the De La Vergne Refrigerating Machine Co., who show effect. They have departed entirely from the beaten track of illuminated signs and the stringing of lamps, and have endeavored rather to represent the effect of interior illumination—a matter of some little difficulty, in view of the location and surroundings, and the fact that heavy machinery lends itself very little to interior decoration.

The whole of the decorative effect is in pure Empire style. A very handsome screen forms the background on which are painted two scenes illustrated with the use of "Hornsby-Akroyd" engines in connection with electric lighting. Each of these pictures is surrounded by the gilded frames of the conventional wreath and the typical Empire torches. The one represents a country home lighted up at night, while the other illustrates the use of the "Hornsby-Akroyd" oil engine in connection with searchlights. The effect is enhanced by illuminating these paintings from behind, and the searchlight is very effective. A man-of-war is painted on the back of the screen, and when the lights in front of the screen are turned off and those behind the scree turned up the searchlight is suddenly projected and the man-of-war springs into view. The illumination screen is very effective and worked in as part of the decoration. A light is placed in each of a series of Empire wreaths forming a frieze along the top, and in addition to these there are four very handsome wall brackets all in correct style. The stand is raised about 6 inches above the ground and is covered by a canopy of blue cloth richly studded with the imperial bee, as are likewise the two curtains enclosing the stand. The floor is in hardwood parqueted, and the furnitures, consisting of a desk and chairs, are authentic specimens of the finest Empire work. The introduction of costly furniture and fittings produces a very rich and pleasing effect.

HORNSBY-AKROYD OIL ENGINE EXHIBIT OF THE DE LA VERGNE REFRIGERATING MACHINE CO.

several examples of the "Hornsby-Akroyd" oil engine, of which they are the sole manufacturers in the United States.

It was to be expected that a firm of their reputation would make a creditable display, and it must be acknowledged that they have succeeded in producing a very unique and pleasing

All the lights on the stand are produced by a Hornsby-Akroyd oil engine running a C. & C. generator by link belt. The dynamo is placed behind the engine, so that the space occupied is not much greater than the floor space required for the engine. The De La Vergne Co. prefers the use of a belt with a single en-

gine (although the Hornsby-Akroyd oil engine has been built with two cylinders and directly coupled to dynamos with satisfactory results), for the reason that they are unwilling to sacrifice the great characteristic of the engine, viz. its simplicity, by introducing the application of several cylinders.

It is claimed, and apparently not without reason, that this engine can be run by a coachman or gardener, and as a matter of fact hundreds of these engines are in constant operation on plantations and farms where skilled labor is entirely out of the question.

A good deal of the prevalent skepticism as to the possibility of obtaining a steady light with an internal combustion engine will be dissipated by an examination of the light produced on this exhibit. The elaborate display of the De La Vergne Co. would have been of little account if the running of their engine had not been of the highest quality, and the total absence of flickering of the light is the subject of much favorable comment.

The engine itself is so well known as to need hardly any comment. It was put on the market about five years ago, and without any blowing of trumpet or beating of drum, it has steadily worked itself into public favor until it has attained an unassailable position. The Hornsby-Akroyd engine is in use in all parts of the world, and has been adopted by most of the European Governments in the face of the fiercest competition. The United States Government has not been behind, and is using it practically to the exclusion of all others for lighthouse service, torpedo service and searchlights.

It is interesting to note that the engine now running at Madison Square Garden is identical with over thirty recently ordered for the United States torpedo stations. Among other well known Government applications it may be mentioned that the Statue of Liberty is lighted by a Hornsby-Akroyd engine, and that the largest searchlight in the world at Navesink Heights will also be operated by this engine. In fact, over 100 of the Hornsby-Akroyd engines are, or shortly will be, in use by the United States Government.

It appears to be an engine admirably adapted for use in a country house, for lighting, pumping water, etc. The claim of absolute reliability seems to be justified by the fact that on every day since the opening of the Exhibition it has been started before 2 o'clock and shut down at 11 o'clock at night, and in no single instance has there been a stoppage for any reason whatsoever during those hours. Its simplicity is obvious from an inspection, there being a total absence of hot tubes, lamps, electric igniters, batteries, air compressors, etc.

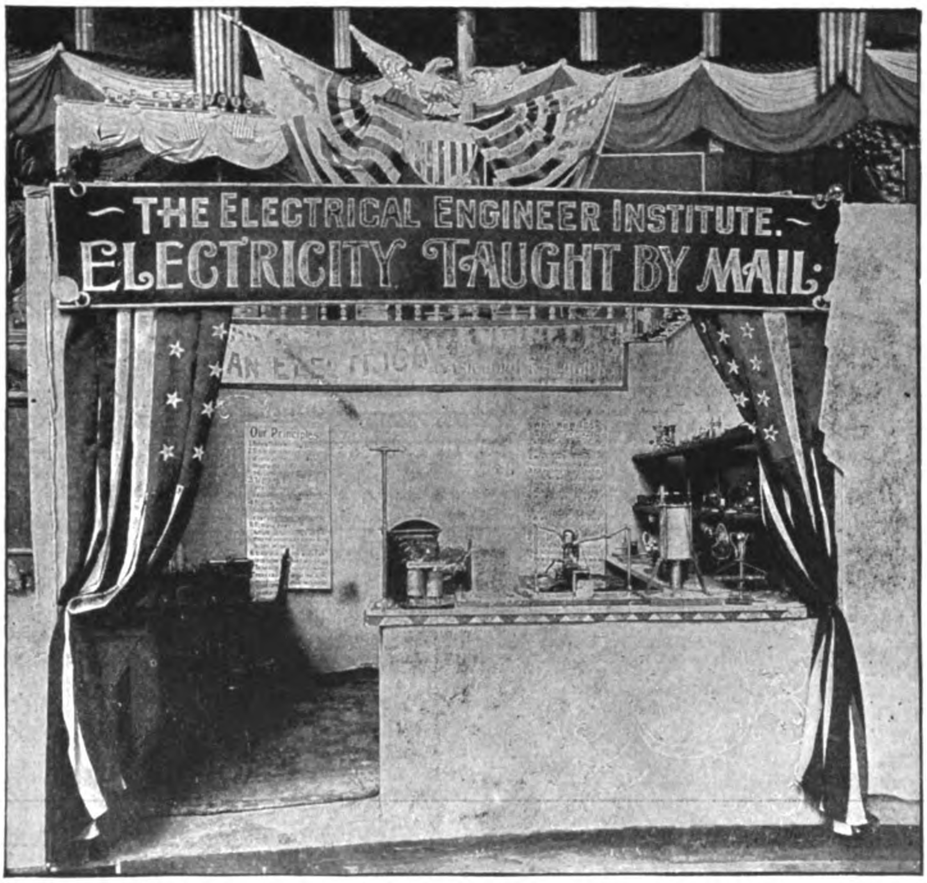
In the exhibit are displayed four engines, one of 32 h. p., one of 4 h. p. and two of 1½ h. p. each. The engines are very strong, of massive proportions and well adapted for the continuous hard work to which engines of this class are subjected. The rather large proportions for a given horse power are due to the fact that a very moderate pressure is produced by the combustion of the oil which conduces to the durability of the engine. Upon the whole it may be considered a thoroughly practical engine, designed for continuous hard work in the hands of unskilled labor rather than a scientific toy for the illustration of theories. The exhibit is in the efficient charge of Mr. E. H. Cox.

The Electrical Engineer Institute of Correspondence Instruction.

THE Electrical Engineer Institute of Correspondence Instruction has an exhibit on the main floor which is undoubtedly a great centre of attraction to both the layman and expert. This enterprising institution has, at great expense, fitted up a most complete laboratory at its booth, and nightly demonstrations are given with the various apparatus.

The experiments include almost all the important electrical manifestations, methods of generating electricity and many of the practical applications. The demonstrations begin about 8 p. m. and continue until the closing hour. The interest taken in these experimental demonstrations is clearly manifested by the large gatherings in front of the booth which almost block the aisle. There seems to be no thinning out of the crowd in front of this popular booth from the beginning to the end of the evening.

Mr. Joseph Sachs, of the Institute staff, is in charge of the laboratory, and in demonstrating the various experiments ac-



BOOTH OF THE ELECTRICAL ENGINEER INSTITUTE.

companies each with a clear and lucid description, worded so that even the non-technical mind can grasp the principles involved. To still further simplify and clear up the various electrical phenomena, a booklet entitled "Popularized Electrical Experiments" has been prepared, in which all the experiments are arranged in graded order, each being accompanied by an excellently clear, although concise, description. The audience of this popular lecture course is always eager to get these booklets, which are distributed free of charge and certainly furnish a most excellent syllabus of electricity and its applications. The elaborate and artistic Institute catalogues are also in great demand.

The experiments range from the elementary demonstration of the deflection of a needle to the more complex phenomena of the electric furnace and electro-chemical effects. Particularly prominent, however, are the production of calcium carbide, the electric water pail forge, electric welding, electric arc metal working, and the experimental demonstrations of the principles upon which the motor and dynamo are based. Many who are at first attracted by these fascinating experiments become intensely interested, and a large number of students have already been enrolled at the Exhibition. Judging from the multitude of inquiries and the favorable opinions of prominent electrical men at the Show, the Institute is an important factor in electrical engineering education.

As an educational effort the "Popularized Electrical Experiments" are undoubtedly worthy of the highest commendation. The Exhibition management, fully appreciative of this fact, has requested the Institute to present the lecture on a larger scale in the Concert Hall. This invitation has been accepted, and popular lectures on electricity with brilliant experiments are now delivered by Mr. Sachs three nights each week. These lectures are free to all and are to be regarded as a contribution to popular education by the Institute.

Mr. Herman A. Strauss, general manager of the Institute, and an able corps of assistants, including Mr. Willard M. Miner, Mr. Edward Hyans, and Mr. M. Cushner, are at the Exhibition every evening. They are almost continuously in consultation with eager inquirers, and enrolling students.

The fact that the guarantee of The Electrical Engineer accompanies all the Institute's work has proven to be an inducement to many, who fully appreciate the absolute good faith, trustworthiness and technical reliability of the instruction offered them.

Exhibit of the Fort Wayne Electric Corporation.

THE Fort Wayne Electric Corporation, of Fort Wayne, Ind., are ever at the front in presenting novel features of display. To the right of their space, which by the way, is a most prominent one, being directly to the west of the centre, and surrounded by four aisles, is a 37½ k. w. low frequency (60 periods) alternator, generating current at 1,000 volts, whose current, after passing through transformers, reducing the voltage to 100, is utilized in showing the operation of the Corporation's new enclosed alternating current arc lamps, and their latest types of lamp hour, ampere hour and kilowatt hour, alternating recording meters. The operation of these meters, on different loads, is gracefully shown by the addition of an ammeter and several banks of lamps connected to lamp switches. The visitor is shown two kilowatt hour meters connected in series and operated on a single lamp. The straight line law common to these meters is clearly shown by observing the number of revolutions on a given bank of lamps, the revolutions per lamp minute of the meter being known. The alternating current generated is further utilized by one of the Fort Wayne Electric Corporation's self-starting single phase synchronous motor of 5 h. p. capacity. Although these machines have been but two years on the market they have made a vast number of acquaintances and friends. Their load starting feature insures a great popularity. The alternator is directly connected to a four-pole motor, which operates it at a speed of 900 revolutions per minute.

To the left of the space one of the well known "Wood" arc dynamos is represented in the shape of an 80-light 2,000 c. p. unit. The improved regulator with which this machine is equipped is conspicuous for its compactness and simplicity, being entirely on

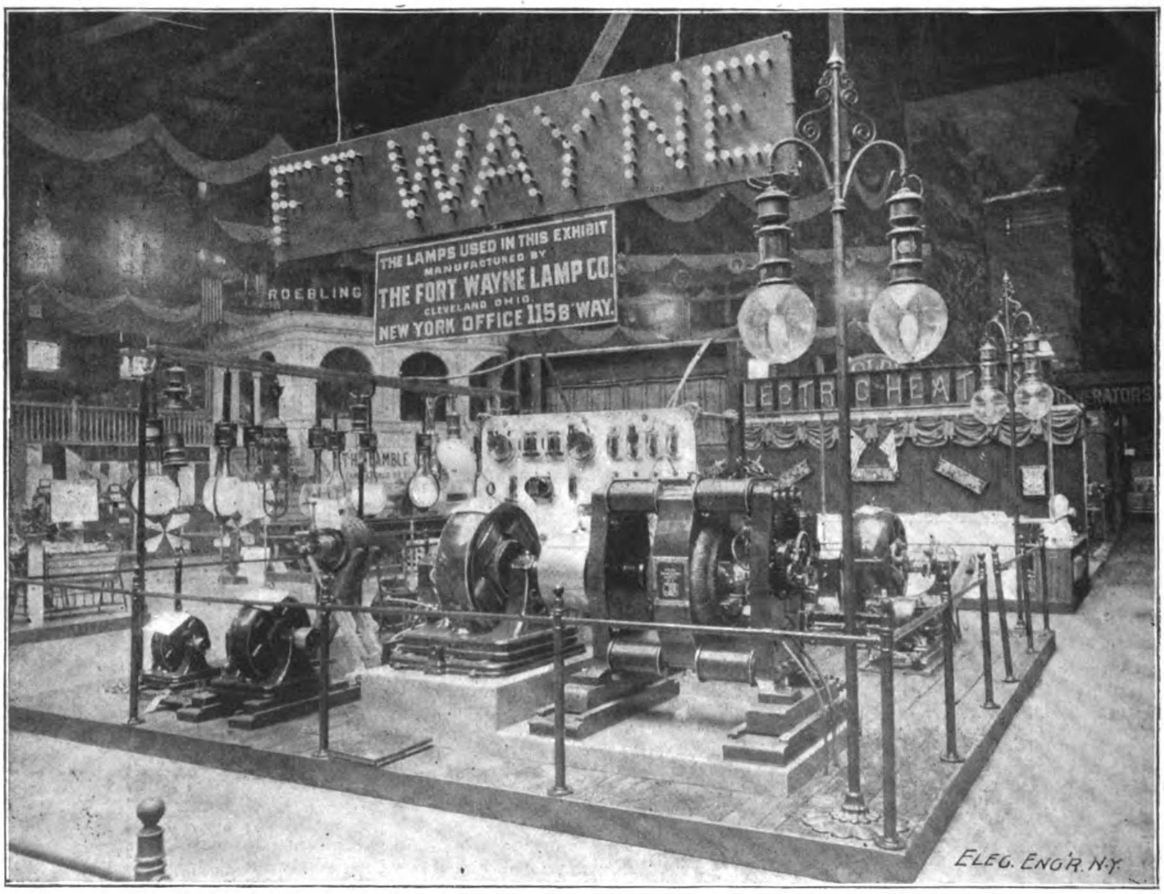


EXHIBIT OF THE FT. WAYNE ELECTRIC CORPORATION AND THE FT. WAYNE LAMP CO.

the machine, so that all wall controlling devices and outside regulator connections are done away with. The arc dynamo is connected to a rack of arc lamps which, although they do not load the machine, are sufficient to show its operation. The machine is driven by a belted direct current multipolar motor.

The rest of the exhibit includes lighting transformers, arc light transformers, small motors and a handsome marble combination switchboard containing necessary apparatus for the handling of the alternating and arc circuits. Mention should also be made of a new commutator burning device shown in operation. It consists of a simple tool operated by hand for facing the commutator perfectly true with the bearings, a most valuable adjunct to an electrical plant. The Fort Wayne Electric Corporation is ably represented here by Mr. F. A. Wunder, assisted by Mr. J. C. Lott and Mr. Thos. A. Nathans, from the New York office, at 115 Broadway.

The Fort Wayne Lamp Co., of Cleveland, O., who are connected with the above, and who exhibit, in conjunction with it, have a unique display of their famous tipless incandescent lamps. The frosted lamps in the massive "Fort Wayne" sign, on the meter board, and in several large baskets distributed about the booth, give the visitor an opportunity of minute examination, as well as an appreciation of their general artistic effect. Mr. T. E. D. Ritchie, Eastern sales agent, is in charge, and explains very effectually the merits of the lamps.

The Apparatus for the Telegraph Tournament.

J. H. Bunnell & Co., with wonted enterprise and generosity fitted up the platform in the Concert Hall at the Electrical Exhibition with apparatus for the telepraph tournament, and Mr. Bunnell was himself most active in his efforts to have things go smoothly and well. As an old-timer he has lost none of his interest in achievements at the key, and he keeps in close touch with all the new men coming to the front or "going to the front."

The R. Thomas & Sons Company's Exhibit.

A VERY striking and instructive exhibit on the main floor is that of the R. Thomas Sons Company, of East Liverpool. Ohio. The booth is beautifully draped in blue and white, and on a star surrounded by small porcelain knobs appears the name of the company in gold letters. They are exhibiting their well-known porcelain specialties, among which should be mentioned the triple petticoat insulator which is said to be puncture proof and the strongest insulator mechanically as well as the best electrically. The attendant at the booth shows the latter quality

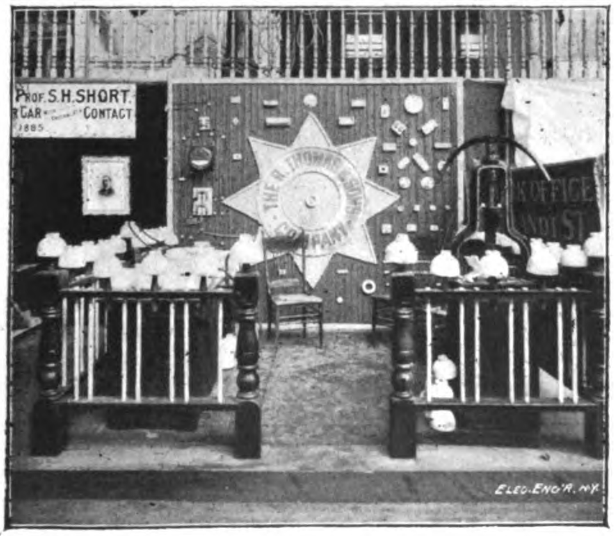

EXHIBIT OF R. THOMAS & SONS.

very strikingly by submitting insulators submerged partly in salt water and thoroughly drenched with it, to a potential of 60,000 volts, which is produced by a Westinghouse testing transformer. The current which at first leaks over the surface will jump a number of inches from one terminal to the other after the surface has become dry. These tests are made on glazed as well as unglazed insulators and all of them stand the test admirably. Besides these insulators, the company exhibit the "Boch Glaze Filled" high potential insulators, described in The Engineer, April 7. A miniature triple petticoat insulator is given away by the company as a souvenir.

The Exhibit of the Peckham Truck Co.

THE Peckham Truck Company are exhibiting their numerous and well known products in various portions of the Exhibition. In their own space on the main floor are found neat and carefully constructed models of the 14-B short wheel base swivel trucks and one of their 14-D swing bolster maximum traction trucks. They are also exhibiting one of their Metropolitan special high speed single trucks under the car

EXHIBIT OF THE PECKHAM TRUCK CO.

body in the Stephenson Car Co.'s exhibit. There is also found in the Walker Co.'s exhibit one of the company's 7-B-X Excelsior trucks, showing a different arrangement of the cantilever side frame design, which is the distinguishing feature of the Peckham single trucks. These two applications of the Peckham trucks are the operative portion of their exhibit, and are in constant use during the evening. A detailed description of the company's exhibit appeared in our issue of May 12.

Paragon Fan and Motor Exhibit.

ANYONE whose good fortune has permitted him, or rather whose good sense has taught him to supply himself with a fan motor during the summer months, can understand why

EXHIBIT OF PARAGON FANS AND POWER MOTORS.

the space wherein 106 fan motors are all in continuous operation is constantly surrounded by an appreciative throng. Such an exhibit is that of Mr. J. P. Williams, the well-known manufac-

turer of the "Paragon" fan and power motors. In pyramidal form he has mounted 106 14-inch and 16-inch fan motors of various colors and design, of the bracket as well as desk types, and the whole is capped by a huge Paragon motor in the form of a big white windmill rotated by a $\frac{1}{4}$ h. p. motor, and having affixed to its large white wooden blades 150 incandescent lamps. The effect of this display is refreshing, and were it not for the cooling of the air around this booth, one would hardly know that the motors were in operation, so noiselessly do they run.

There are shown besides these motors, $\frac{1}{4}$, $\frac{1}{2}$ and 1 h. p. power motors, a 1 h. p. generator, and a $\frac{1}{2}$ h. p. motor with prolonged shaft, having mounted on one end an emery wheel and on the other a buffing wheel. Numerous ceiling and column fans are shown and in one corner of the booth is shown one of the special features of the show, namely, a cradle rocked by means of an electric motor. Within this cradle is a large doll, and above it is a sign bearing the inscription, "The hand which rocks the cradle rules the world." And no one will deny, after seeing this splendid "Paragon" exhibit, that the domain over which the electric motor holds sway is extensive and important. The exhibit is in charge of Mr. J. P. Williams, assisted by Messrs. J. H. Campbell and A. W. Turner.

Notes on Various Interesting Exhibits.

THE BABCOCK & WILCOX CO., who have furnished the two 265 h. p. boilers of their complete forged steel construction, built for 200 pounds' pressure, referred to in detail in our issues of May 5 and 12, have lately added a very interesting

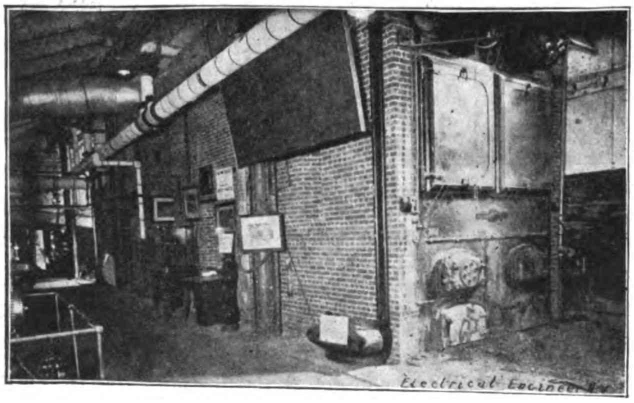

EXHIBIT OF BABCOCK & WILCOX BOILERS, BASEMENT.

feature to their thoroughly practical and useful exhibit. It is a complete model of a longitudinal section of a B. & W. boiler, showing the construction of every portion of the boiler as well as the setting. It is placed under a glass case and is always surrounded by interested visitors to the Exhibition.

THE BOSSERT ELECTRIC CONSTRUCTION CO. have

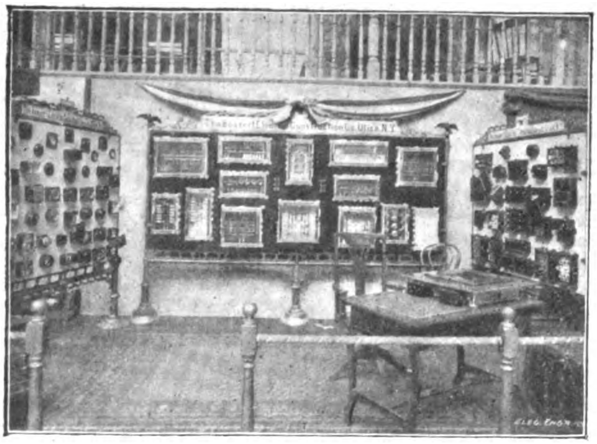

EXHIBIT OF THE BOSSERT ELECTRIC CONSTRUCTION CO.

arranged a very tasteful exhibit on the main floor, showing a complete line of steel drawn outlet and switch boxes, representing the latest improvement in wall boxes, as they are constructed entirely of one piece of wrought steel, being absolutely indestructible and thoroughly fireproof. They also exhibit various types of steel-clad, self-contained main junction and distribution boxes. This type of box is designed especially to meet the objection of the underwriters and electrical engineers generally to a combustible box enclosing a panel board. They are thoroughly fireproof and are designed for any number or arrangement of circuits with or without switches.

THE K. & W. COMPANY, of Pittsfield, Mass., manufacturers of Hardy incandescent lamps, composite dynamo brushes, hanger boards, spark arresters and anti-spark lubricating compound, are making a very creditable exhibit of these products,

EXHIBIT OF THE K. & W. CO.

in charge of Mr. C. Houliston. A detailed description of the exhibit was given in our issue of May 5, but special mention may again be made of the excellent incandescent lamp product of this company, which attracts no small amount of attention.

THE AMERICAN ENGINE CO., of Bound Brook, N. J., have arranged a very tasteful exhibit in the generating section

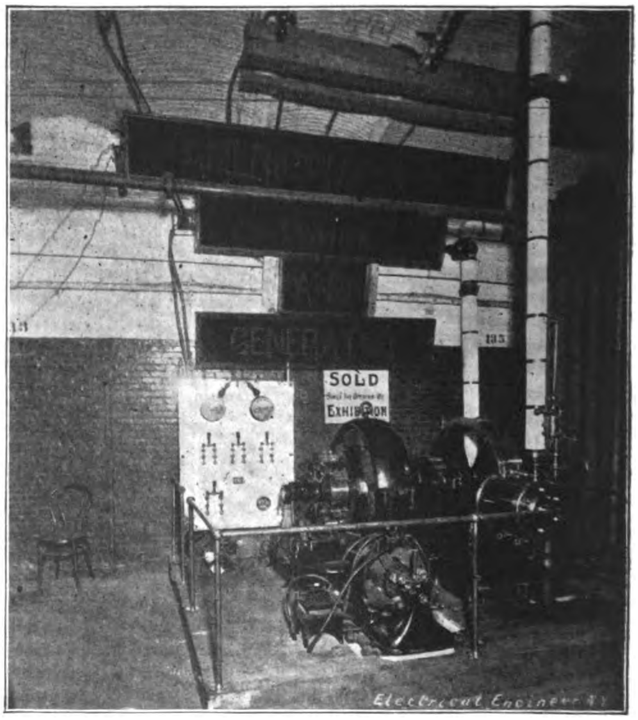

EXHIBIT OF AMERICAN BALL ENGINE AND DYNAMO, BASEMENT.

opposite the battery of boilers and adjoining the Engineering Picture Gallery. They are showing an American-Ball engine direct connected to a 25 kilowatt generator, and unless a person

were to get very close to the unit, so that he can actually see it moving, he would never know that it was in operation, so well balanced are the engine and dynamo. It operates absolutely noiselessly and is a model of mechanical and electrical design. Besides this unit there are shown a 5 h. p. multipolar motor and a neat switchboard equipped with switches, measuring instruments and rheostat. An attractive sign composed of red miniature incandescent lamps announces the exhibit which might almost pass unnoticed, due to the noiselessness of the operating machinery. The exhibit is in charge of Mr. Jos. Englesby.

The Nowotny Electric Co.'s Exhibit.

The Nowotny Electric Company, Cincinnati, Ohio, are exhibiting in a handsomely decorated booth their new style enclosed arc lamp, which is claimed to be superior to other lamps in that the general arrangement of the lamp is such that it is extremely easy for even an inexperienced person to recarbon and take care of it. The resistance being inside the outer globe, prevents any possible danger of burning out the magnet coil or scorching the ceiling. There are no adjustments to get out of order. Owing to the simple manner in which the inner globe is held in position there is ample room for it to expand without danger of breaking it. The outer globe is held in position in such a manner that it can be raised or lowered without detaching it. Another feature of the exhibit which is quite new and is attracting considerable attention is an arc lamp connected singly across a 220 volt circuit taking 2½ amp., with 160 volts across the arc. Mr. Chas. A. Aull, the electrical engineer of the company, and the designer of the lamps, represents the company at the Exhibition.

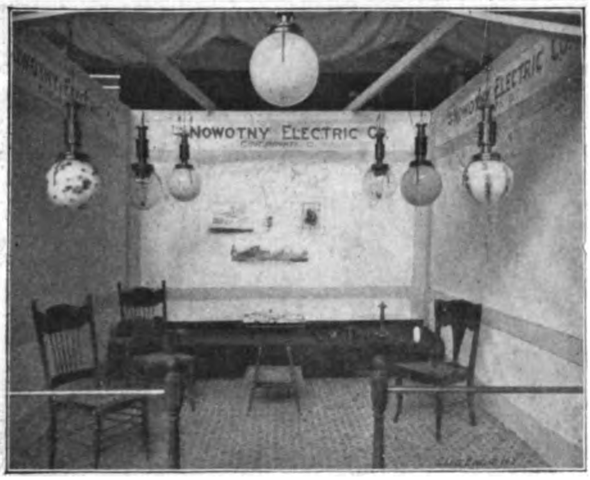

EXHIBIT OF THE NOWOTNY ELECTRIC CO.

The Diesel Motor Co.'s Exhibit.

UNDOUBTEDLY no exhibit in the operating department at Madison Square Garden attracts more attention than that of the Diesel Motor Co., and for good reasons. The remarkable performances of the Diesel motor had served to whet the curiosity of power users, and many are the inquiries which the company's representatives are obliged to answer.

The Diesel motor on exhibition is of 20 horse power, coupled directly by a rigid coupling to the armature shaft of a C & C generator. The motor was not built for electrical work, but it is an ordinary 20 horse power stationary motor intended to run machinery by belt drive. It runs at only 170 revolutions per minute, is a large cylinder motor, and like all internal combustion motors, works on the four stroke cycle. Time was not available to change the gearing for higher speed, desirable as that appeared for electrical work. It seemed therefore a bold undertaking to attempt to make it drive an electric light generator. But public interest in the Diesel motor has been so aroused and the opportunity to exhibit it at the Electrical Exhibition seemed so favorable, and above all, the directors of the company have such absolute faith in the motor, that they determined to exhibit it even under these adverse conditions.

Delays in shipment and in the custom house, reduced the time for preparation. The only change that could be made in the time available, was to supply the engine with a somewhat heavier fly-wheel than necessary for its ordinary work, and after two days of preparatory run, it was set up in the Exposition and carries its load of lights with less than 1½ per cent. variation in speed. It requires less than a minute to start the engine

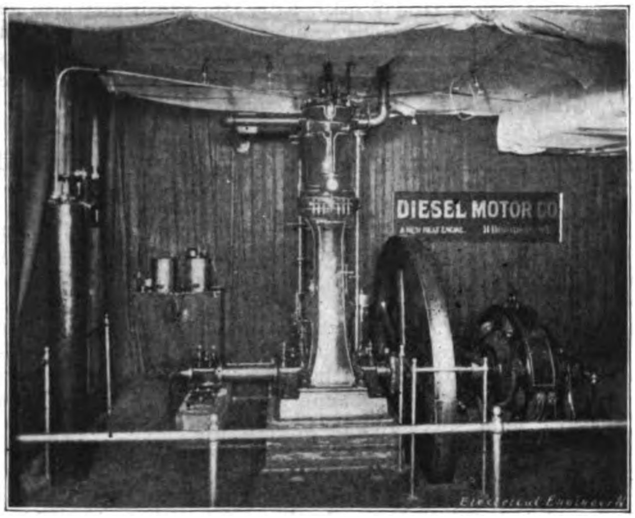

EXHIBIT OF DIESEL MOTOR CO., BASEMENT.

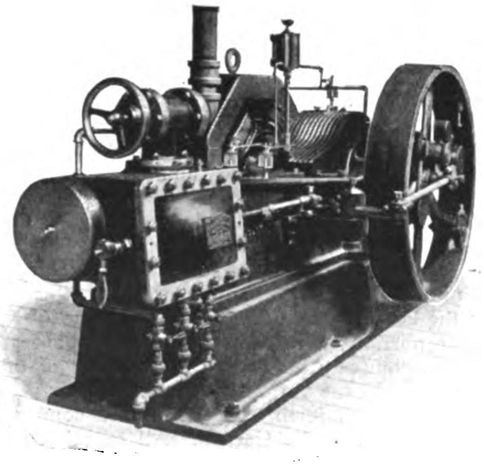
when perfectly cold, and within two minutes it is running at full speed with its load. We believe that this is the first instance on record that a single cylinder internal combustion engine has ever accomplished these results. Those who have studied the working of the Diesel motor find the reason for this success in its controlled and perfect combustion and the absence of any explosive action. A full description with illustrations of the internal construction of this interesting machine will be found in The Engineer of Feb. 17, 1897.

Burhorn and Granger.

Messrs. Burhorn & Granger, 136 Liberty street, New York, and Stephen Girard Building, Philadelphia, Pa., are exhibiting in operation a 9 inch by 12 inch "Woodbury" high speed engine, direct connecetd to a 25 kilowatt "Eddy" generator. This engine is of the latest improved type, equipped with "Shepherd" governor with which they guarantee a regulation of one-half of one per cent. for all variations of load, and also their automatic oiling system, to which they invite attention. The regulation can be tested by visitors with the aid of a recording Schaffer & Budenberg tachometer at the exhibit.

Another portion of their space is taken up with a sectional model of the "Woodbury" cylinder and steam chest, showing



"WOODBURY" ENGINE DIRECT CONNECTED TO EDDY GENERATOR.

the "Woodbury" valve, the method of adjustment and means of providing for entrained water. This portion of the exhibit proves very interesting to visitors, who are thus enabled to see the inside of the same size engine as that which is running.

Attention is called to Messrs. Burhorn & Granger's exhibit by a revolving illuminated sign, aided by an attractive souvenir card which they distribute and on which announcement is made of the various houses which they represent, including the Stearns Mfg. Co., of Erie, Pa.; Harrisburg Mfg. and Boiler Co., of Harrisburg, Pa.; Philadelphia Engineering Works, Philadelphia, Pa., and Union Iron Works, Erie, Pa., and it may also be noted that since the previous exhibition they have opened a Philadelphia office under the management of Messrs. Charles E. Machold, M.E., and A. H. Riddell. The exhibit is in charge of Mr. Granger.

The Joint Exhibit of Stanley & Patterson and the Ziegler Electric Company.

ON account of the great variety of products displayed, their tasteful arrangement and excellency, the large booth jointly occupied, on the Arena Circle, by Messrs. Stanley & Patterson, of New York, and the Ziegler Electric Co., of Boston, has always been a centre of attraction at the Show. At the back of the booth against pale green drapery are arranged the various products of Stanley & Patterson, such as telephone supplies, consisting of long distance and exchange telephones, toll line cabinet sets, electric light specialties, switches, etc., electric bells, annunciators, wire, fans, desk lights, shades and Shelby incandescent lamps. These lamps are tastefully arranged so as to form the letters S. & P. and present all colors of the rainbow. Fifty-five of these lamps are used, which are particularly striking on account of their splendid natural coloring, and the globes without tips. Two incandescent arc lamps are suspended from the ceiling.

The Ziegler Electric Co. are exhibiting on the counter at the front of the booth and in glass cases, their numerous products, embodying many decided novelties and improvements. There

STANLEY & PATTERSON'S AND ZIEGLER ELECTRIC CO.'S EXHIBIT.

are shown measuring instruments and testing sets of an infinite variety, such as voltmeters and ammeters, galvanometers, bridges, keys, etc., medical apparatus, Geissler tubes, and a complete X-ray outfit, consisting of induction coils, tubes, condenser, etc., as well as of batteries, fan motors, lamps, fixtures and switches. The chief feature of the exhibit, however, is the searchlight and stage lamp manufactured by this company. Fourteen of the latter are used for the illumination of the tower, and in another portion of this issue their admirable features are explained. The company have placed a number of their well-known searchlights in the various booths, and their penetrating, steady rays have called forth many favorable comments from the numerous visitors at the Garden. All questions regarding the Ziegler products are cheerfully answered by Mr. Chester Snow, the treasurer of the company, and Mr. A. F. Stanley is on hand to look after the interests of Messrs. Stanley & Patterson.

COMR. F. E. BARKER, of the Massachussetts Gas and Electric Light Board, was in New York last week, and a visitor to the Electrical Exhibition.

The Faries Mfg. Company's Exhibit.

THE Faries Mfg. Co., of Decatur, Ill., manufacturers of the Faries universal adjustable electric lamp holders, aluminum and steel electric lamp shades, and fire and water tube boiler cleaners, have recently established an Eastern office at 136 Liberty street, New York city, under the management of Mr. A. W. Koenig, who has arranged a very neat, attractive and interesting exhibit at the Electrical Exhibition, which is illustrated below. The exhibit is located on the promenade just above the main floor, adjoining the New York Telephone Company's Theatrophone exhibit, and we would advise all our readers who visit the show to call and see it, as we are positive the universal adjustable electric lamp holders exhibited by this firm will interest everybody, electrical contractors, engineers, electricians, electrical supply dealers, as well as the general public, who may be fortunate enough to use electricity in their offices or private residences. The placing of the Faries universal adjustable electric lamp holders before the public meets the long felt want of being able to get your light just where it will be of service to you, both in reading and working. Some of them are adjustable in four or five places, so that it is very easy to arrange them to throw your light anywhere that you may wish it, by merely adjusting the fixture at any angle necessary. These fixtures are manufactured of the finest material, and the best of workmen are employed only by the firm, so that no efforts are spared to turn out the best fixtures on the market, at the most reasonable prices. They are made in about thirty different designs of portable and stationary desk

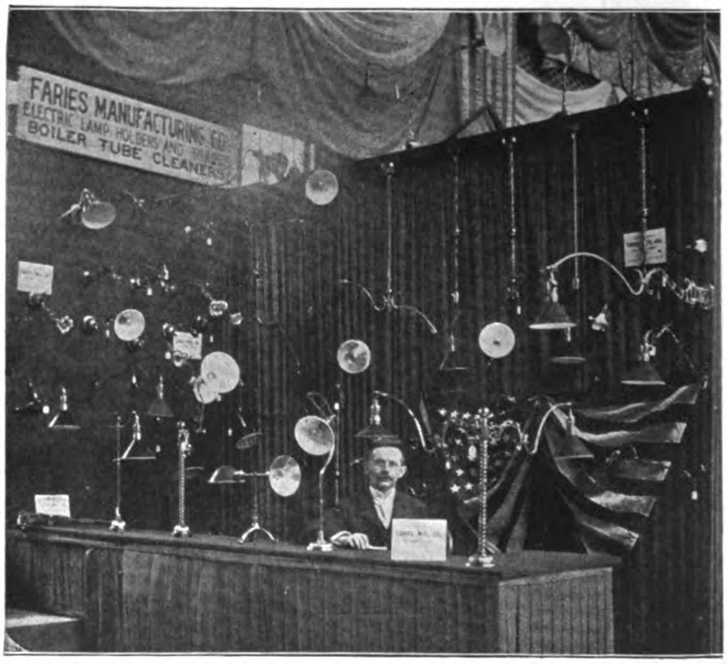


EXHIBIT OF THE FARIES LAMP HOLDERS AND FIXTURES.

and table lamps, side wall fixtures, chandeliers, pendant hall lamps, and dental lamps. They are all very unique and attractive in design, while not at all elaborate, thus making the cost very reasonable. The aluminum and steel electric lamp shades or reflectors are made in three styles—the parabola or half shade, the cone shaped, and the ceiling shade. They are not only shades, but reflectors of the very highest order. The holder reaches well over the shank of the lamp, leaving the shade to begin at the top of the filament, thus enabling a smaller shade of same angle to cover the lamp, as well as a larger one with old style of holder. Being smaller, it is lighter and less in the way; being lighter it is easier to handle and to be borne by light fixtures at different angles, and is not apt to rack or pull the socket to pieces as heavier shades are. They fit any socket and are easier put on or off, and have a neater appearance than the old style of shade and holder. They are seamless, and are made both of steel and aluminum; both are enameled either black or green outside, and the steel ones are finely enameled white inside, while the aluminum ones are highly polished inside. The parabola has the further advantage of throwing the light from the side of the lamp, which gives evener illumination, and

as the holder swivels on the socket, the shade can be turned to throw the light to any angle.

The advantage of the fire and water tube boiler cleaner manufactured by this firm is that it expands when shoved forward in the tubes and collapses when pulled backward, so that it will never get stuck. It is easily adjusted for variations in sizes of tubes, and has a ram which enhances the ease and facility of operation, especially when tight and uneven places in the tubes are encountered. There is no leather or rubber about the cleaner, and it does the entire work without the use of steam or water. Mr. A. W. Koenig, who is in constant attendance, will be pleased to answer all questions relating to the above products or send catalogues to any one on application. He would also request the company's patrons in the Eastern States to send inquiries and orders to the New York office, in order to save time and expense in shipping.

The Barrows Vehicle Company of New York.

THIS company are represented by the president, Fred. W. Duncan, and have on exhibition two types of their tricycle electric vehicles; these vehicles differ from all the others in that they have only three wheels and the load and steering is done by means of the single wheel which runs in front, being modeled closely after bicycle methods. They have another peculiarity in that the body is interchangeable so that different styles of bodies may be mounted upon the same running gear, one being independent of the other. The frame is of steel tubing and bent

EXHIBIT OF BARROWS ELECTRIC VEHICLES.

in the form of a goose-neck, the end of which rests upon the top of the single wheel.

As noted above, a framework or saddle is provided in which the batteries are carried on each side of the driving wheel, and these, mounted a little below the centre, give the vehicle great stability. The motor is mounted against the carrying frame in rear of the batteries and is geared for one or two horse power, depending upon the size of the vehicle. The power is communicated by means of a pinion working on an internal gear attached to the spokes of the driving wheel. The gear is of large diameter, giving to the motor great leverage and permitting of a very simple construction in that the power is applied so near to the rim of the wheel, that heavy axle strains are avoided. The driving wheel is 38 inches in diameter and the rear wheel 28 inches; all of the bicycle pneumatic tire type.

The leads from the batteries are brought up to a circular controlling apparatus in front of the driver and by a movement of the handle three speeds are obtained, four, eight and twelve miles per hour forward and a backward speed of four miles. The front wheel is so evenly balanced that the steering is very easily done. A bicycle type of lamp is employed and the light is produced by means of acetylene gas.

The brake is applied by means of a foot lever and works on the rim of the tires of the rear wheels. All the wheels are provided with ball bearings, and all the equipment is light and graceful having sufficient strength, however, for all purposes. The weight of the smaller vehicle is 1,200 pounds; 640 pounds is assigned to the batteries. The batteries are a special type manufactured by Sipe & Sigler, Cleveland, Ohio. The small vehicle exhibited has a capacity for a run of 20 miles and the large one for 40 miles where the roads are reasonably good; the company do not recommend the electric type of horseless vehicles where there are steep hills, or where mud and sand or snow predominate. The batteries are charged with 110 volts direct current, and, where they are charged from city mains, the average cost, it is claimed, is about one and a half cents per mile, but with the special plant which the company design and

EXHIBIT OF THE BERLIN IRON BRIDGE CO., MAIN FLOOR.
(For description see issue of May 12.)

furnish and which they recommend, consisting of a dynamo and gas or gasoline burning engine, the charging is estimated at less than one-third of a cent per mile. The batteries are guaranteed for five years service, and the cost of maintaining is claimed to be not over $75 per year, while that of the motor is estimated at $10. Counting the care of horses and the comparative amount of room occupied by horseless vehicles with that of the ordinary vehicles together with the animals, the expense is very much less than that of maintaining the ordinary vehicles, for, unlike the horses the batteries eat only when they work.

LETTERS TO THE EDITOR

Early Trolley Roads.

Let me assist Mr. Henry in the matter of early trolley roads. In 1886 a double trolley road was in operation, connecting the village of Montreux, Chillon, and Villeneuve, at the head of Lake Geneva, in Switzerland.

The two conductors were hollow brass or copper tubes, open at the bottom. In these tubes were metallic plungers 8 to 10 inches long, with wire brushes at each end of them, to make good contact with the tubes.

The wires were fastened to the centre of these plungers. They were flexible cords twisted into a rope, and as the car ran, it dragged the plunger after it.

The power came from a dynamo, up the mountain side, moved by a water wheel; and the boy up there, who acted as chief engineer of his power station, was telephoned from time to time, for more or less current.

Altogether this little road was a curious affair. Where it wound through the narrow, crooked streets—too narrow for sidewalks and poles—the trolley tubes were supported by handsome iron brackets, projecting from the building fronts.

I presume the road is still in existence. When I saw it, in 1886, it was in good order, and bade fair to run for years. I do not know how long it had been built.

Buffalo, N. Y. H. HASKINS.

SOCIETY & CLUB NOTES

Mr. A. E. Kennelly, Prest. A. I. E. E.

Mr. A. E. Kennelly.

The American Institute of Electrical Engineers in electing its new Council has done well in the choice of Mr. A. E. Kennelly for the presidency. That gentleman illustrates in his career the wide range of Anglo-American interests, for, born of English parents in Bombay in 1861, he has been resident in this country for ten years past, and has done much to raise the standard of American electrical engineering. Mr. Kennelly was for many years active in submarine cable work, and in 1887, received the premium of the Institution of Electrical Engineers of England for a paper on localizing cable faults, as well as the Institution Fahie premium in 1888. During the latter year, he resigned from the service of the Eastern Telegraph Company and became electrician to the Edison laboratory. In 1894 he joined Prof. Houston in establishing the professional firm that bears their name, and in the publication of a large amount of valuable literature, such as the "Electrical Engineering Leaflets," published by this journal. Mr. Kennelly is a fellow of the Royal Astronomical Society, a member of the Franklin Institute, the English Institution of Electrical Engineers, etc., etc. In 1895 he received the honorary degree of Doctor of Science from the University of Pennsylvania for original work in electrical research.

American Institute of Electrical Engineers.

The annual meeting of the Institute for the election of officers and the transaction of other general business was held in New York city on May 17. The report of the Council was submitted, giving, among other things, the membership of the Institute as 1,098, made up of 2 honorary, 352 regular and 744 associate members. The income for the year amounted to $10,027. Committees were appointed to count the ballots and examine proxies. While these committees were at work attention was called to the large number of associate members in comparison with the number of regular members, and it was suggested that the Examining Committee recommend to such members as it considered eligible that they apply for transfer to full membership. The fact that only 150 of the new badges had been sold during the year, and that only 23 old ones were exchanged was commented on. The election of the following officers was announced: President, Arthur E. Kennelly; Vice-Presidents, Prof. Robert B. Owens, William Stanley, Jr., Dr. Cary T. Hutchinson; Secretary, R. W. Pope; Treasurer, George A. Hamilton; Managers, Herbert Lloyd, Dr. Samuel Sheldon, Prof. George F. Sever and Charles P. Steinmetz.

At the meeting of the Executive Committee in the afternoon the following associate members were elected: Felix Louis Cadou, Superintendent and Electrician, Washington Street Railway Co., Washington, Ind.; Thomas Dempster Electrical Engineer, General Electric Co., Schenectady, N. Y.; Paul Letheule, Electrical Engineer, commissioned by French Government, 24 Front street, Schenectady, N. Y.; Livingston Johnston, Jr., Islip, N. Y.; Howard Joslyn, Assistant Engineer, Snoqualmie Falls Power Co., Seattle, Wash.; James J. Mahony, Engineering Assistant to Manager Railway Department, General Electric Co., 115 West 47th street, New York city; Irving A. Taylor, Motor Inspector, Edison Electric Illuminating Co., 360 Pearl street, Brooklyn, N. Y.; Wallace Rupert Turnbull, Foreman of Experimental Room, General Electric Lamp Works; residence, 29 South Arlington avenue, East Orange, N. J.; James H. Winfield, Superintendent Eastern Division, Nova Scotia Telephone, Limited, New Glasgow, N. S.; Fred. W. Wood, General Manager, Los Angeles Railway Co., 1722 South Flower street, Los Angeles, Cal. Total, eleven.

The following associate members were transferred to membership: Edward Burch, Electrical Engineer, Twin City Rapid Transit Co., Minneapolis, Minn.; G. A. Redman, General Superintendent Electrical Department Brush Electric Light Co., and Rochester Gas and Electric Co., Rochester, N. Y.; L. S. Boggs, Pioneer Electric Co., Ogden, Utah; Gustave J. Fischer, Engineer for Tramway Construction Public Works Department, Sydney, N. S. W.; James B. Scott, Electrician and Mechanical Engineer, 227 East German street, Baltimore, Md.

Lecture By Prof. I. Fujioka Before the New York Electrical Society.

FOLLOWING up its success with the lecture by Dr. S. S. Wheeler, the New York Electrical Society made another hit with the lecture on Thursday evening last by Prof. I. Fujioka, on "Electrical Developments in Tokio and the Empire of Japan Generally." The Concert Hall was crowded, and the large audience not only heard an excellent lecture, but was delighted and surprised with a long series of admirable lantern slides of Japan, of Japanese warships and of the war in Corea and China. The latter slides, of purely Japanese origin, were very clever and spirited, and were welcomed with the keenest interest, as were Prof. Fujioka's brief explanations of them. In spite of the fact that he spoke in English, the Professor's remarks were closely followed, owing to his ready command of the language.

Prof. Fujioka's lecture dealt chiefly with the telegraph, telephone, electric light and power, and electric railway work; and it gave statistics in regard to each of these departments. In 1896 Japan had 12,000 miles of land telegraph pole line and 1,122 telegraph offices. The number of messages sent and received in the interior was 22,250,000. At the end of 1896, there were 6 local telephone exchange systems, with 540 miles of pole line and 3,232 subscribers. There are now some 40 central station lighting companies in Japan, and in Tokio alone the number of lights supplied is 50,000, of which 40,000 are furnished by the Tokio Electric Light Co., which has five stations of various types, including three-phase and Edison three-wire. A number of companies have been formed to carry out power transmission enterprises. Two at Tokio are going to develop about 30,000 h. p. from water, transmitting the current forty or fifty miles at 10,000 to 20,000 volts.

Two cities in Japan, Kyoto and Nagoya, have electric street railroads. Two companies have been organized which will equip Tokio with an ultimate 200 miles of trolley road. A large number of other lines are being projected or laid out, making a total of two or three hundred miles, and in much of the work Prof. Fujioka is interested. American apparatus is freely used.

At the close of the lecture a hearty vote of thanks to the lecturer was passed.

New York Electrical Society.

The Society will give a dinner on Friday evening, May 27, at 7:30, at the St. Denis Hotel, Broadway and West Eleventh street, in celebration of its recent work and growth. The price per cover is $2.50. There is much interest in the affair, and the attendance will probably be very large. The dinner will be accompanied by music, etc., and followed by speeches from prominent men.

THE STOCK MARKET

Steady and Dull Markets.

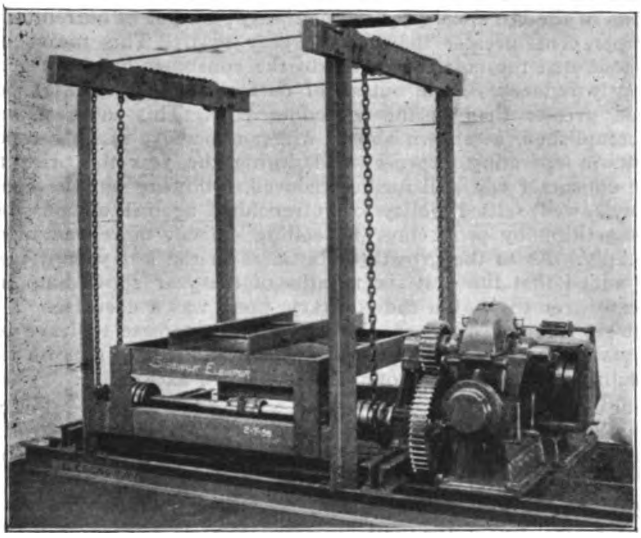
Pending the occurrence of some striking event in the field of war, the various markets of the country have remained quite steady and a trifle dull. Stocks particularly have awaited developments. During the week, 18,889 shares of Western Union were sold, around 88 to 90. General Electric, on sales of 3,237 shares, rose to 36¾. Bell Telephone in Boston was inert. New York Edison was dull at 125.

NEWS AND NOTES

Elevator for Handling Storage Batteries on Cars.

ONE of the greatest troubles experienced in operating storage battery cars in the past has been caused by the difficulty of placing the batteries on the cars, and of replacing the discharged battery with the charged. This unsatisfactory feature was entirely overcome when the battery was placed on the truck of the car instead of under the seats, and was hoisted up from below on to the truck, instead of being shoved in either at the ends or sides of the car. This new arrangement was first used on two storage battery cars which were operated on the Madison Avenue street car line in New York City about three years ago. This feature was further perfected in the equipment of The Englewood & Chicago Electric Street Railway, Chicago, Ill., and has been most successfully in operation on that road for the past eighteen months.

In the first installation a stationary elevator was used for raising the batteries to the car truck. In the Chicago installation there were two elevators placed on a large transfer car



ELEVATOR FOR HANDLING STREET CAR BATTERIES.

which ran at right angles to the street-car track, the whole apparatus being controlled by a man standing on a centre platform of the transfer car. This arrangement was fully described in The Electrical Engineer of Dec. 2, 1896.

During the past few months two of these Chicago cars have been in operation on the Grand Street Cross Town line in New York, but here it was not necessary to use such a large piece of apparatus as the transfer car in Chicago for transferring the batteries. The accompanying engraving shows an elevator which was constructed for the purpose. This elevator was placed below the street-car track, the drum shaft being at right angles to the latter. On the platform of the elevator will be noticed two short pieces of channel iron held rigid and parallel by two tie rods. The small truck on which the battery was placed in the charging pit ran on to these channel irons from a small track placed in the bottom of the pit. When the elevator was at its lowest position, the top of the channel irons was at a level with the head of the pit rail.

A charged battery would be run on to the elevator, and would then be raised by the motor shown in the cut to its position on the car truck above, where it was automatically locked. When the street car had made its appointed run, so that the battery needed recharging, the power would be brought above the elevator, an empty battery truck would be raised, and the battery lowered into the pit. A fully charged battery on this truck would then be pushed on to the elevator, and raised into position as before.

By this method of putting the batteries on the cars, several advantages are gained: 1. As the battery is placed on the car truck, no space is taken up in the body itself. This will allow of putting any sort of a body on the truck desired by the railway company. 2. There is no space taken up in the car barn by the batteries, as they are handled and charged entirely in the battery pit beneath the tracks. 3. There is no odor on the car itself from the acid fumes, and no spilling of acid in the car. 4. The battery is compact, occupying only the space between the two axles on the truck, and is in one tray, instead of two or more trays under the seats.

The operation of The Chicago & Englewood Street Railway has illustrated that a storage battery street railway is a commercial success. The batteries have now completed nearly 20,000 miles without any repairs whatever, and give promise of continued service in the future. As the operation brings down the cost of maintenance of the battery to such a low figure, the total cost per car mile will, it is predicted, compare favorably with any other system of street car propulsion.

Electricity in the Miehle Printing Press Factory at Chicago.

THE Miehle Printing Press Mfg. Co. has made several applications of electrictiy to the work in its factory at 80 North Clinton street, Chicago, which are decidedly in the line of progress, and which go to show that this concern is striving to be thoroughly up to date in its methods. The first application of electricity, aside from shop lighting, was that of driving the portable drills used for boring holes in press frames while the presses are being assembled. It is out of the question to drill many of these large frames in a drill press, as it is desirable to drill most of the holes at a time when the press is being put together. Heretofore some of these holes were drilled by hand. Others were drilled by power furnished by a kind of rope transmission from shafting overhead. Hand drilling was of course slow and expensive because of the labor involved. The rope drive was exceedingly inconvenient and cumbersome as can readily be imagined when it is considered how much work it is to arrange the driving apparatus for drilling in the endless variety of positions called for in the construction of a printing press. There is also constant trouble with the ropes slipping and wearing out. The electric motor offers a very easy solution of this drilling question. It can be put anywhere it is wanted and moved to suit the requirements. The company now has two motors devoted to this work. Each one is mounted on a small hand truck that can be wheeled around from one place to another. On the truck there is not only the motor, but the rheostat and reverse switch. The whole is enclosed in a ventilated box for protection against dirt and flying metal. From the motor to the drill the connection is made by 6 to 8 feet of flexible shafting.

The two motors now in use differ somewhat in details, though both are of the same capacity, 3 horse power. One is a compound wound Excelsior motor with Cutler-Hammer rheostat. The flexible shaft can be attached either direct to the armature shaft or to a shaft geared to the armature shaft to give considerable speed reduction and increased torque on the drill. Any other desired speed reduction can be obtained by the rheostat.

The other drill motor is a 3 horse power Gibbs, placed by Kohler Bros. It has four speeds of spindles to which the flexible shaft can be attached. The armature shaft runs 950 revolutions per minute, the next shaft 543, the next, 428, and the fourth 252 revolutions. The gears are encased in an oil tight gear case. These shafts are all 1 inch in diameter.

With these motors, holes up to 7/8-inch diameter are drilled, and holes 2½ inches in diameter are counterbored.

It is expected to put in circuit breakers to protect the flexible shafts against breaking due to drill sticking or overload.

The power circuit is 220 volts and is maintained separately from the 110 volt lighting circuit. Excelsior machines have recently been put in for both light and power.

Another new feature that this company has adopted is that of testing with an electric motor every press turned out of the factory to find the exact power it takes. This move is one that buyers of presses will appreciate very much, as in these days when no printing office is considered strictly modern unless employing electric motors for the individual driving of each press, of any size, purchasers are anxious to know in advance how much power a press will take, so that the electrical engineer of the installation can intelligently draw up his plans. The

electric motor offers by far the easiest method of testing the power required by a press. The presses will all be tested both with and without type and rollers. In this way any slight defects in the press that might cause it to run unnecessarily hard may be discovered, when otherwise they would not.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued May 17, 1898.

Alarms and Signals:—

ELECTRICAL SAFE PROTECTION SYSTEM. I. Freed, Harrisburg, Pa., 604,033. Filed June 15, 1897. Details of construction.

Conductors, Conduits and Insulators:—

APPARATUS FOR JOINING TELEGRAPH CABLES. H. Menier, Paris, France, 604,258. Filed Dec. 28, 1897. Comprises an elastic cylinder to inclose the cable joint, hollow chambers about the cylinder and means for admitting fluid pressure to the chambers to compress the cable joint.

Dynamos and Motors:—

ELECTROMAGNET HAVING ROTATING FIELDS. W. Langdon-Davies, London, England, 604,055. Filed May 23, 1896. An electromagnet having a rotating field resulting from two windings carrying current differing in phase asymmetrically arranged upon the core and inclined the one to the other at an oblique angle which is the supplement of the angle by which the currents in the two windings differ in phase.

COMMUTATOR BRUSH HOLDER. W. B. Stull, Bayonne, N. J., 604,220. Filed Feb. 12, 1898. Comprises the follower connected with the brush and lazy-tong levers at one end connected with the follower and levers at the other end to the holder, combined with means for exerting spring-pressure laterally against the sides of the levers.

Electro-Metallurgy:—

APPARATUS FOR ELECTRICALLY WORKING METALS. J. D. Bishop, New York, 604,137. Filed May 6, 1897. Particular adapted to the production of continuous lengths of electrical conductors.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. F. W. Steinacker & E. F. Cowley, Cleveland, O., 604,219. Filed April 12, 1897. A lamp of the incandescent arc type adapted for use on a constant potential or incandescent lamp circuit.

Railways and Appliances:—

ELECTRIC LIGHTING SYSTEM FOR RAILWAY CARS. W. F. Richards, Buffalo, N. Y., 604,081. Filed Sept. 16, 1897. The dynamo is driven from the car axle by a belt and the dynamo is movable toward and from the driving axle, so that the belt slips when the speed of the driving axle exceeds that which is necessary to properly drive the dynamo.

ELECTRIC LIGHTING SYSTEM FOR RAILWAY CARS. W. F. Richards, Buffalo, N. Y., 604,082. Filed Sept. 22, 1897. Similar to above.

ELECTRIC LIGHTING APPARATUS FOR RAILROAD CARS. W. F. Richards, Buffalo, N. Y., 604,083. Filed Sept. 25, 1897. Similar to above.

ELECTRIC LIGHTING APPARATUS FOR RAILROAD CARS. W. F. Richards, Buffalo, N. Y., 604,084. Filed Oct. 11, 1897. Similar to above.

ELECTRIC LIGHTING APPARATUS FOR RAILROAD CARS. W. F. Richards, Buffalo, N. Y., 604,085. Filed Oct. 14, 1898. Similar to above.

RAIL CONDUCTOR FOR ELECTRIC SYSTEMS. L. E. Walkins, Springfield, Mass., 604,098. Filed Aug. 18, 1897. Comprises the combination of several rails in end-to-end arrangement, an intermediate one consisting of two opposite longitudinally ranging metallic sections and an intermediate rail of non-conducting material supporting and insulating the sections, end portions of the intermediate rail overlying the ends of the metallic sections and serving to insulate the respective metallic side sections of their ends from the rails adjoining the ends of the intermediate sectional rail.

ELECTRIC LIGHTING APPARATUS FOR CARS. W. E. Wilhelm and W. F. Richards, Buffalo, N. Y., 604,101. Filed Oct. 23, 1897. Combines with a railway vehicle and its axle, an inclined track arranged lengthwise on the under side of the vehicle, a carriage mounted on the track, a dynamo adjustably attached to the carriage, and a frictional driving mechanism whereby the dynamo is driven from the axle.

TROLLEY FOR ELECTRIC RAILWAYS. S. H. Short, Cleveland, Ohio, 604,196. Filed Sept. 26, 1896. Consists of an overhead conductor, and a trolley arm mounted upon a car, combined with a horizontal cylindrical roller mounted upon the upper end of the trolley arm, a sleeve secured upon the roller between its ends, a rod extending through the roller and the ends of the arm and ball bearings placed upon the rod, and fitting in the ends of the roller.

Switches, Cut-Outs, Etc.:—

CIRCUIT CLOSER. W. D. Kennedy, Easton, Pa., 604,157. Filed March 25, 1895. Comprises a base, a thermostatic plate thereon, a central manual closer, a perforated guard for the thermostat, and a cap for the manual closer engaging and securing the guard on the base.

Telephones:—

TELEPHONE SWITCHBOARD PLUG. J. Taylor, Heathercliffe Helsby, England, 604,094. Filed Nov. 21, 1896. A triple contact plug embodying a single central bolt, which, with the aid of suitable nuts, binds together all the respective parts of the stem and interior so that the loosening of the nuts on this bolt enables the plug to be taken entirely to pieces.

COMBINED ANNUNCIATOR AND SPRING JACK. G. W. Sutton, New Rochelle, N. Y., 604,340. Filed April 8, 1897. Combines a switching device and an apertured pivoted shutter barring access to the same, except through the aperture whereby a plug for operating the switching device must be passed through the shutter to reset it.

REPORTS OF COMPANIES

The Chicago Edison Co.'s Annual Report.

THE statement of the Chicago Edison Company for the year ending March 31 last makes an even better showing than anticipated. Gross earnings increased about 8 per cent., while operating expenses increased less than 4 per cent. Operating expenses, in proportion to gross earnings, are now the smallest in the company's history. The way in which the company has broadened its business and at the same time, by liberal expenditures on plants, reduced operating expenses, is partially illustrated by a comparison between the figures for the last fiscal year and those for the fifteen months ending March 31, 1894, the latter including the whole World's Fair period. In the fifteen months of 1893-'94 gross earnings were $480,000 more than in the last twelve months, but operating expenses were $475,000 larger, so that in the last year the company earned practically the same amount net as in the fifteen months ending March 31, 1894. The fiscal statement, however, does not begin to show what the company has really accomplished in the way of reducing cost of production and enlarging its field. The figures as to output are much more striking. Thus in the last fiscal year the company's output of current was 70 per cent. greater than in the year 1894. This means, of course, that the cost of current to the consumer has been very greatly reduced. The output of current this year was 15 per cent. greater than in the preceding year. This increase was accomplished, as shown above, with an increase of only 4 per cent. in operating expenses and during the year the price to the consumer was still further reduced, following out the company's well settled policy of intrenching against all possible competition by producing and selling current more and more cheaply. As to the growth of business in the last year it may be added that the first six months of the year showed no increase over 1896. On the contrary, there was a decrease. The last six months, however, showed enough increase to leave receipts for the twelve months $113,255 ahead. From 1894 on the results achieved by the company are shown as follows:

Year ending March 31.	Gross.	Optg.	Earned on stk.	Per ct. optg.
1895	$1,437,042	$953,377	$328,537	66.3
1896	1,461,084	898,517	404,432	61.5
1897	1,548,608	948,934	419,340	61.3
1898	1,661,863	985,338	449,844	59.3

The last year, as compared with the preceding year, shows larger earnings, reduced proportion of operating expenses and a larger surplus after dividend requirements were met. Out of this year's surplus $40,000 was charged to depreciation reserve. The figures for 1898 and 1897 are:

EARNINGS.

	1897-98.	1896-97.	Increase.
Gross	$1,661,863	$1,548,608	$113,255
Operating expenses	985,338	948,934	36,404
Net	676,524	599,674	76,850
Interest	226,680	180,334	46,346
Earned on stock	449,844	419,340	30,504
Dividends	398,072	397,518	554

The growth of the business during the year is shown by the following statement of business connected:

Incandescent lamps	259,496
Arc lamps	5,896
Motors (horse power)	8,415
Total equivalent in 16 candle power lamps, March 31, 1898	436,083
Total equivalent in 16 candle power lamps, March 31, 1897	355,140
Increase for fiscal year	80,943

The capital stock is the same as a year ago, but the company has issued $708,000 of the new bonds during the year. The proceeds went to improvement of plants, as that item increased $922,878. These are the only important changes shown by the balance sheet. The following gives all the items for two years with comparisons:

ASSETS.	March 31, 1898.	March 31, 1897.	Changes.
Plants, real estate, etc.	$9,553,208	$8,630,330	Inc. $922,878
Work in progress, etc.	161,549	136,405	Inc. 25,144
Accounts received	211,110	197,799	Inc. 13,311
Cash	86,826	206,541	Dec. 119,715
Open accounts	48,457	......	Inc. 48,457
Total	$10,061,151	$9,171,075	Inc. $890,076

LIABILITIES.			
Capital stock	$4,975,900	$4,975,900	......
Bonds and debentures	4,458,000	3,750,000	Inc. $708,000
Accts. and notes payable	279,213	131,066	Inc. 148,147
Open accounts	......	17,842	Dec. 17,842
Depreciation reserve	240,000	200,000	Inc. 40,000
Insurance fund	28,000	20,000	Inc. 8,000
Surplus	80,038	76,267	Inc. 3,771
Total	$10,061,151	$9,171,075	Inc. $890,076

Depreciation reserve as here shown represents amounts charged out of earnings and set aside for permanent improvements to plants.

The company improved its already commanding position during the year by a number of operations which resulted in landing some small electric light companies in the hands of friendly interests, where they will be operated in harmony with the Edison Company's ideas. Thus the property formerly owned by the Chicago Illuminating Company, the Hyde Park Thomson-Houston Company, the Englewood Electric Light Company and the Western Light and Power Company, has during the year changed ownership and come into the possession of people who will be entirely in harmony with the Edison Company. In fact, President Insull of the Edison Company has been elected president of two of these smaller concerns.

A dispatch from Chicago, dated May 17, says: "The Edison interests are now in absolute control of the entire electric lighting business of the City of Chicago. They have within a few months purchased the stock of every independent electric light company in active operation in the territory bounded by South Evanston on the north, and the Indiana State line on the south, and these companies are now operating under the direction of President Samuel Insull of the Chicago Edison Company.

Among the concerns taken in are the following: Hyde Park Electric Light and Power Company, Hyde Park; Thomson-Houston Electric Light Company, Mutual Electric Light Company, People's Light and Power Company, People's Electric Light Company, Motor and Power Company, Englewood Electric Light and Power Company, Chicago Illuminating Company, Western Light and Power Company, Edgewater Electric Light Company, West Chicago Electric Light and Power Company, and Enterprise Power, Light, and Heat Company.

These companies are not to be merged with the Chicago-Edison Company, but will be consolidated into one company, under the name of the Commonwealth Electric Company, which will be controlled by the same interests as the Chicago-Edison Company.

PERSONAL

MR. E. W. ROCKAFELLOW, of the Western Electric Co., who was stationed at Camp Townsend as First Lieutenant of Company B, 47th Regiment, has been appointed Captain of Co. M, 47th Regiment, now stationed at Camp Black. Mr. Rockafellow is to be congratulated on his promotion.

SIDNEY LANIER. The appreciation of Sidney Lanier, by Th. Bentzon (Madame Blanc) which "The Living Age" presents in translation in its numbers for May 14 and May 21, is probably the fullest, most discerning and most delicate tribute ever paid to this poet, whose qualities have been imperfectly appreciated among his own countrymen.

MR. JOHN RICE, who is so well and favorably known to the carbon consuming trade, has accepted a position with the Phoenix Carbon Mfg. Co., of St. Louis. We wish Mr. Rice every success in his new home in St. Louis.

MR. J. J. MOORE, the well-known electrical engineer, and now president of the Auburn, N. Y., Electric Light Co., has just celebrated his silver wedding at Springfield, Mass. His son, J. D. Moore, is a graduate of the Massachusetts Institute of Technology, and is in the profession.

MR. E. W. LITTLE, so well known in the electrical field from his long connection with the management of leading concerns in it, has become associated with Nicoll, Herrick & Berg, the bankers and brokers, and has opened a branch office for them in the Townsend Building, 25th street and Broadway. His many friends will wish him abundant success.

LEGAL NOTES

The Condict Electric Car Controller Patent Sustained—Electric Car Co. of America and Thomson-Houston Co. vs. Hartford & West Hartford Co., et al.

Last week Judge Townsend, of the United States Circuit Court for the District of Connecticut, handed down a decision sustaining on its main points the patent granted to George H. Condict, No. 393,323. This patent refers to a car controller, originally designed for storage battery cars, so arranged that at the time of changing the connections resistances are inserted to cut down the current so as to prevent sparking, these resistances being cut out of circuit as soon as the new connection is made. The patent also shows four ways of coupling the motors in series parallel arrangements. The defendants apparatus was constructed under the von Zweigbergk patent, No. 546,664, which embodies a "dissipator."

In its opinion the Court says: "In view of all the facts proved, I find and hold that the invention of Condict is a broad one; that he is entitled to the beneficial uses of his invention as developed in the development of the art, and that defendants in thus using his combination infringe the patent. Condict was the first inventor of a practical embodiment of this system of co-operating resistances. His invention has been modified and developed to meet the exigencies of the greater voltage and other inventions in the railway trolley art.

The Court holds that claims 20, 21, 22, 27, 28, 29 and 31 of the Condict patent are infringed and orders an injunction and accounting.

The complainants, General Electric Co., were represented by Messrs. Betts, Sheffield & Betts; Messrs. Charles E. Mitchell and William F. Henney appeared for the defendants.

The Sprague Railway Motor Suspension Patent—Claims 2 and 6 Sustained by the U. S. Circuit Court of Appeals—Sprague Electric Railway & Motor Co. vs. the Union Railway Co. and Walker Co.

The United States Circuit Court of Appeals has rendered a decision in the suit brought by the General Electric Co. against the Walker Co., for infringement of the Sprague patent No. 324,892, covering the method of railway motor suspension. The claims said to be infringed read as follows:

"2. The combination of a wheeled vehicle and an electro-dynamic motor mounted upon and propelling the same, the field-magnet of said motor being sleeved upon an axle of the vehicle at one end, and supported by flexible connections from the body of the vehicle at the other end, substantially as set forth."

"6. The combination, with a wheeled vehicle, supported upon its axles by springs, of an electro-dynamic motor flexibly supported from such vehicle, and centered upon the driving-axle thereof, substantially as set forth."

"9. The combination, with a wheeled vehicle, of an electro-dynamic motor centered upon the driving-axle thereof at one end, a spring-support for that end of the motor from the truck or body of vehicle, and relieving axle wholly or partly of dead-

weight, and a spring support for the other end of motor from the truck or body of vehicle, substantially as set forth."

In an opinion written by Judge Shipman, the Court, after reviewing the case at length, holds that claims 2 and 6 are infringed, and orders an accounting on those claims. Claim 9 is held not to be infringed.

Condenser Electro-Magnets.

During the past three years an important interference contest has been pending in the United States Patent Office on one of the patents owned by the American Bell Telephone Company, and an application for patent of Mr. John T. Williams, the inventor of the "portelectric" carrier system, the subject of which is the condenser electro-magnet; that is, an electro-magnet embodying in the same structure an electrical condenser. In this device the winding of the magnet forms one electrode or plate of the condenser, while another interwound conductor forms the other electrode, the insulating material of the wires serving as the dielectric. The purpose of this invention is to suppress the evil effects of self-induction in the magnet winding, and so to quicken or sharpen the response of the armature, and is especially effective on alternating or rapidly interrupted current circuits. The case was recently finally decided in favor of Mr. Williams.

Mr. Wm. A. Rosenbaum, of New York, appeared for Mr. Williams, while Mr. W. W. Swan, of Boston, and Messrs. Pollock & Mauro, of Washington, D. C., represented the Bell Company.

Telephone Switchboard Litigation in Detroit.

The Western Electric Co. has brought suit against the Detroit Telephone Co. and W. L. Holmes to restrain them from alleged infringement of the Leroy B. Firman patent on multiple switchboards, which was recently sustained in California, but, it appears, expires in January, 1899.

TRADE NOTES & NOVELTIES

The Upton Midget Enclosed Arc Lamps.

The manufacturers of the Upton Midget enclosed arc lamps, recognizing the fact that many plants using enclosed arc lamps for alternating currents which at the present time are operated at the high frequency, may desire to change over to the low frequency current at no distant day, have so designed their lamp that it will operate on both frequencies without change of adjustment. When called for by customers the lamp is furnished so that the only change required is in the terminal connection on the lamp in the binding posts, which are properly marked. The lamps can be adjusted to take from 4 to 6½ amperes, as may be desired; that is, an average consumption of from 300 to 500 watts per hour. The Standard Thermometer & Electric Company are also prepared to equip each lamp with a reflector over the arc, and opal shade in place of an outer globe. The Standard people claim that the sales of their lamp are increasing from users all over the country on account of its steady burning and noiseless operation.

They also report that their enclosed arc series lamp for constant current circuits of from four to seven amperes has proved to be the best lamp of this type on the market. Large numbers of them are being sold for commercial lighting, and also for street service. Among recent sales for street lighting they mention the municipal lighting plants at Taunton and Hudson, Mass.; the Tecumseh Electric Light Co., Tecumseh, Mich.; Fox River Lighting Co., Green Bay, Wis.; Oshkosh Gas Light Co., Oshkosh, Wis., all of which made their purchases after thorough tests.

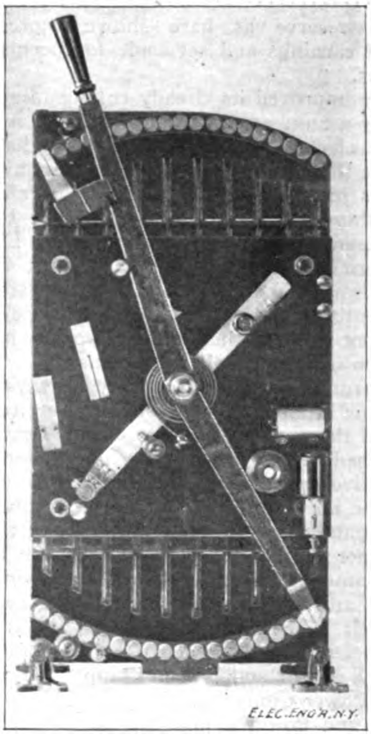
The Standard people have recently issued a new catalogue which gives full description and cuts of their enclosed arc lamps for all circuits. Copies of this catalogue will be mailed on application to the home office at Peabody or any of their branch offices mentioned elsewhere in this paper.

The Ward Leonard Printing Press Rheostat Controller.

A rheostat for accomplishing all that is desired in the control of a printing press is not an easy thing to produce as many press builders can testify. The Ward Leonard Electric Co. have devoted special attention to this work, and we illustrate herewith one of their latest forms of printing press controllers.

The rheostat occupies very little room, and can be attached on the side of a press in the most convenient place for operating it without taking up enough space to be objectionable on this score. The rheostat has 35 steps, so that all sparking at the contacts is eliminated absolutely, yet the operating lever is only moved through about 50 degrees from one extreme limit to the other. The rheostat contact lever can be left in any position and thus any resistance desired can be kept in circuit with the motor. The resistance of the rheostat is so great that when all of it is in circuit the press can be stopped under conditions of lightest load.

The movement of the rheostat lever to insert all of the resist-



WARD LEONARD PRINTING PRESS RHEOSTAT CONTROLLER.

ance causes it to engage with a separate automatic switch lever which it moves to a position in which the circuit is closed. After being thus closed the automatic switch lever is held closed under normal conditions by a shunt magnet across the full e. m. f. A vertical solenoid magnet having a plunger like the ordinary circuit breaker provides the overload safety device. Upon overload current from any cause this plunger is drawn upward by the action of magnetism acting against gravity and knocks open a switch, opening the circuit of the holding magnet, and thus causing the release of the automatic switch lever which opens the circuit, the final breaking of the current occurring on renewable carbon contacts, as shown in the illustration.

At various points around the press, as desired, push buttons are placed by which the automatic switch lever can be released by merely pushing any one of these buttons, thus instantly stopping the press. One of these buttons is also placed on the rheostat plate itself, thus providing the simplest and quickest means of opening the circuit and stopping the press.

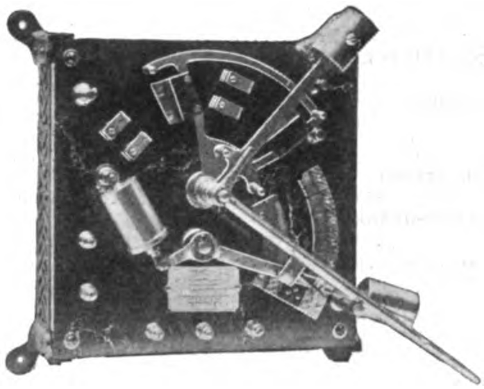
The rheostat shown in the illustration is regulating a 15 h. p. 250 volt Thresher motor upon a printing press in the establishment of Munroe & Co., of New York city.

THE PARTRIDGE CARBON CO., Sandusky, Ohio, have succeeded in producing a carbon for enclosed arc lamps which they claim is as good as the best imported carbons on the market. These carbons are now burning in the lamps of McIntire, Adams-Bagnall, Nowotny and Bergmann makes, at the Electrical Exhibition.

New Zimdars & Hunt Automatic Motor Starter.

WE illustrate herewith a new type of automatic motor starter which has just been put upon the market by Zimdars & Hunt, 127 Fifth avenue, New York. This device is extremely simple in its operation and has many features which should recommend it to prospective users of such apparatus. The various operations required to properly start a motor are accomplished automatically by the interaction of a number of suitably disposed levers, two of which are weighted.

In operating, the main arm is raised (by rope or other suitable means), and this carries the rheostat lever up over the rheostat contacts, inserting the full starting resistance into the armature circuit. Immediately the rheostat arm reaches the top contact the main knife switch is closed, the field energized and the circuit closed through the armature and its starting resistance. At the time the main switch is closed the rheostat lever is auto-



ZIMDARS & HUNT NEW AUTOMATIC MOTOR STARTER.

matically released and travels downward, under the action of gravity, over the rheostat contacts gradually cutting out the starting resistance. The rate of travel of this rheostat lever can be regulated over a wide range by a pivoted air dash-pot of improved form. The point of release can also be adjusted with relation to the time of closing of the main switch.

This starter bears evidence of careful designing throughout, the absence of springs, solenoids, and other devices of an unreliable character being especially noticeable. The details are representative of the latest and most approved practice, all contacts, for instance, being of the knife form, with those of the rheostat being capable of adjustment.

The workmanship on these articles is up to the well-known standard maintained by this firm, and calls for no further comment. For motors operating on elevator, pump, crane, blower, and such other work, these starters should be found especially desirable. On account of the simplicity of the design the firm is enabled to sell these articles at remarkably low prices. A very attractive folder, "Bulletin C 1," just issued, gives complete prices in all sizes, from ½ to 25 horse power for all voltages, and can be obtained upon request from the above firm.

The Pyramids Not in It For Longevity.

The Leclanche Battery Co., of 117 East 131st street, New York, have received the following letter from Wells & Gunde, jewelers, New Haven, Conn.:

"We have two of your Gonda cells in a self-winding clock in our store. They have been in use not quite eleven years and now they do not work as they should. The zinc and solution have been renewed two or three times, but nothing else has ever been done to them and we think there must be some trouble with the carbons. Will it be necessary to get new batteries, or can you furnish us with new carbons, and if so how much will they cost?"

The Jersey Electric Company's Standing Offer.

THE renewal of burned-out incandescent lamps and making them as good as new has been brought to such a state of perfection by the recently organized Jersey Electric Company, of 744 Broad street, Newark, N. J., that they are now making a standing cash offer for 1,000,000 or more burned-out lamps. They put in new cellulose filaments and sell the renewed lamps at a greatly reduced rate. Besides carrying on an extensive business in renewed lamps, the company purchase scrap copper, for which many uses can be found in the arts. Mr. Harry Gregory is treasurer and general manager of the company, and is well known in electrical circles. Mr. Thomas G. Westcott is general sales agent and is now establishing several large sales agencies throughout the States.

Willard Batteries in Paris.

Messrs. Sipe & Sigler have received orders for Willard batteries from the Riker Electric Motor Co., of New York, and the Fischer Equipment Co., of Chicago., for motor vehicles sold in Paris.

Berly's Universal Electrical Directory for 1898.

This excellent directory, published by H. Alabaster, Gatehouse & Co., London, covers its immense field in an admirable manner, improving yearly. There are about 1,100 pages of directory matter, including in the following sections 23,794 distinct names, as follows: British, 9,918; Continental, 7,872; American, 4,080; Colonial, 1,924. This is a gain of 1,136 names over 1897. The main groups are subdivided and classified in various ways for convenient reference, and a great deal of useful, miscellaneous information is given.

NEW YORK NOTES.

AMERICAN DISTRICT STEAM CO., of Lockport, N. Y., is constructing an exhaust heating plant at Erie Pa., which will utilize the exhaust from the Merchants and Mfr's Electric Light Co.'s station, and also that from the station of the Electric Motor Co. The supply from these two stations will be brought together and distributed through a 12-inch main for heating the principal public buildings and residences of the city. A similar plant is being constructed at York, Pa., for the Edison Electric Light Co. of that place.

MESSRS. H. B. COHO & CO. have issued an exquisite little brochure with dark green paper cover. In it they call attention to the apparatus they sell; some of their recent installations, among which may be mentioned the panel boards for the Empire Building; to their guarantee to make good any defects which appear in their installations within one year from completion; and their aim to do only high grade work, which means low operating cost, with high efficiency. Messrs. Coho & Co. are now well located in their new quarters at 30 Cortlandt street, with vastly increased facilities for conducting the growing business which has made this concern so prominent.

NEW YORK EDISON CO. reports for April gross income of $260,609, an increase of $54,466 over April, 1897; or a gross increase for the four months of $212,656 and a net increase for the four months of $73,168.

LONG ISLAND R. R. CO. is issuing this year two handsome books entitled "Unique Long Island," made up of phototones, and "Long Island," a descriptive pamphlet. The summer train schedule goes into effect June 23, and, with fine trolley service all over the western end of the island, makes this seaside resort more attractive and available than ever.

WESTERN NOTES

THE WALKER CO., of Cleveland, has arranged with Mr. W. H. Emanuel, a large machinery merchant, to represent it in Denver, with headquarters on Tremont street, opposite the Brown Palace Hotel.

ELECTRIC APPLIANCE CO. have recently concluded the general distribution of their Fan Catalogue for the season of 1898. In sending out catalogues to a very large list of buyers it is very often the case that some are overlooked. The Electric Appliance Company would be very pleased to hear from any of the trade who have not received a copy of this handsome catalogue, as they are anxious to place the same in the hands of every possible user or purchaser of fan motors.

THE OHIO ELECTRIC SPECIALTY MFG. CO., of Troy, Ohio, are making an exhibition of dynamo brushes at the Elec-

trical Exhibition, the material being in charge of Messrs. Machado & Roller.

THE new air tight open circuit battery called the Badt Hermetic Cell is receiving the approbation of all engineers and electricians who have been obliged to deal with the troublesome question of primary batteries. The oil seal, which so positively prevents the evaporation of the liquid, the creeping of salts, and the constant premature disintegration of zincs, is the latest novelty in batteries, and is a feature which strongly recommends this cell for use. The Western Electric Company of Chicago, which recently announced in its advertisement that it was headquarters for batteries of various kinds, desires to state that the Badt Hermetic Cell is also added to its list of batteries.

NEW ENGLAND NOTES

BROOKFIELD, MASS. The new power station and car house being erected by the Spencer, Warren & Brookfield Street Railway Company, at Brookfield, Mass., will have steel roof trusses and covering furnished by The Berlin Iron Bridge Company, of East Berlin, Conn. The dynamo and engine room roofs of this building will be lined with the Berlin Company's patent anti-condensation roof lining, which is now almost universally used for roofs of this nature throughout the country. It prevents the condensation of moisture from the underside of the roof covering, which, if it should collect and drop upon the machine beneath, would cause considerable damage.

PHILADELPHIA NOTES

ORDERS FOR STORAGE BATTERIES. The Electric Storage Battery Company has closed a $150,000 contract with the Government for batteries to be used in torpedo boats. Recent contracts with the Government for mines, etc., amounted to $250,000.

ERIE BALL ENGINES.—The city of Union Springs, Ala., is about to instal an electric light plant. Mr. Charles Doughty, Randolph, Mass., has recently ordered for his electric light plant at Randolph, Mass., a 200 vertical cross compound engine direct connected to 120 k. w. generator. Both these engines are furnished by the Ball Engine Co., Erie, Pa.

ADVERTISERS' HINTS

A. N. PALMER & CO., 219 E. Baltimore street, Baltimore, Md., are carrying a full stock of electrical supplies and will cheerfully send prices on all goods in that general line.

JAHL & CO., 123 Liberty street, New York, submit a list of sizes of batteries they carry in stock, one variety of which is specially made to operate spark coils.

A. L. BOGART is now located at 123 Liberty street, New York, where he will continue to supply the many gas lighting specialties manufactured by him.

HART & HEGEMAN MFG. CO., Hartford, Conn., will, on request, send a catalogue of the famous "Hart" switches, containing wiring diagrams and other useful data.

THE AUTOMATIC SWITCH CO., Baltimore, Md., have added to their "ad" a list of agents and the territory in which they are represented.

THE FULLER CO., Detroit, Mich., claim to manufacture the cheapest, most compact and efficient motor for independent service of any nature.

ALBERT B. HERRICK, E.E., is now located at 120 Liberty street, New York.

THE AMERICAN ELECTRIC HEATING CORP., Cambridge, Mass., say that it only needs a little encouragement on the part of central station managers to make electric heating apparatus fully as popular with the public as gas or oil stoves.

THE WAGNER ELECTRIC MFG. CO., St. Louis, Mo., advertise single-phase self-starting alternating current power motors.

THE C & C ELECTRIC CO., 143 Liberty street, New York, announce that they have in preparation a new bulletin treating upon electric hoists fitted with their celebrated closed type iron-clad motors, which will soon be ready for distribution.

THE K. & W. CO., Pittsfield, Mass., offer incandescent lamps at interesting figures.

THE M. C. BULLOCK MFG. CO., 1183 W. Lake street, Chicago, call attention to their central valve engines and invite requests for full information.

ELECTRIC LIGHTING

The Development of the Central Station.—II.[1]

BY SAMUEL INSULL, President Chicago Edison Co.

It is not my wish to address you on the scientific or technical side of central station development. I have thought it necessary to go at length into the early work of the art more for the purpose of giving you some idea of the position to which Mr. Edison is entitled as the father of central station work. My limited knowledge of the technique of the business would not permit me, even if I wished, to discuss the details of his early work, or of the early work of other experimenters; but I assure you that daily familiarity with the operation of one of the largest central stations in this country gives me a higher and higher appreciation of the simplicity and thoroughness and adaptability to all purposes of electrical distribution of the great work accomplished by the "Wizard of Menlo Park."

As a result of the experiments at Menlo Park, Mr. Edison, early in the winter of 1880, started to get together the necessary data for the establishment of a central station and distributing system in New York, in the district bounded by Wall street on the south, Nassau street on the west, Peck's Slip on the north, and South street on the east, a territory covering about 2,000 feet square. He had each house thoroughly canvassed to show the number of lights in use, the number of hoistways and elevators, and the horse power of the engines running machinery. You will find on the walls around us the blue prints of these original canvasses. On one blue print you will find an enumeration of the power in use in that district, and on the other blue print a record of the lights there used. As a result of this canvass, the Edison Electric Illuminating Company of New York was formed, and drawings prepared for a central station, which was erected at 255 and 257 Pearl street, the capacity of the station being 2,000 horse power, and the district fed by a system of half-round copper mains and feeders, the mains being enclosed in lengths of iron pipe and insulated by a bituminous compound, each length of main being between twenty and twenty-one feet, so that it was possible to take off a service at each house.

Time will not permit me to go into the details of construction of this, the first central distribution system. You will see, by referring to the outline drawings of the station which I have with me, that the boilers were placed down below and were of the horizontal water-tube type, made by Babcock & Wilcox, carrying a pressure of 125 pounds, the steam machinery and dynamos being of the direct connected type and placed on a steel structure not dissimilar to that of some portions of the elevated railroad structure in New York.

Great care was taken in figuring out the system of mains and feeders, an immense plot of the district being represented by a series of resistances showing in miniature the probable consumption of current in the various parts of the district. It should be remembered that the path to be followed was practically unknown, that electrical distribution on a large scale was as much of a hidden secret as an unexplored continent, and the remarkable thing is that this first experimental system was a practical success and a return on the money invested was being earned before electricians at home and abroad would recognize the success of the undertaking. It is but natural that many devices were used which were subsequently absolutely discarded. For instance, an elaborate system of resistances placed in series with the feeders was employed for maintaining an even pressure, entailing a considerable waste of energy. The lamp employed was not more than one-half as efficient as that used to-day, while the cost of manufacture was many times greater, and it had not one-quarter of the life of the present commercial incandescent lamp.

It might be well to pause for a moment and picture the condition of the art at that time: I refer to the winter of 1880. The plans for the central station were completed, the details of construction of the conductors in the street were all on paper, the dynamos and electrical instruments had no existence except on the draughting board, practically nothing was known of modern methods of insulation or house wiring, the socket and switch in use to-day had not been thought of, the miscellaneous devices now considered necessary in connection with house wiring had not been considered. In addition to the development of the system and its installation, manufacturing establishments had to be created in which to manufacture the first material needed, and Mr. Edison and his corps of assistants had to abandon the experiments of the laboratory and the designing of the draughting room to equip and manage shops in which to manufacture the apparatus necessary, from the generator to the lamp. Others have followed the beaten track, others have improved upon the methods employed, but the conception of the system, the perfecting of the original apparatus, its manufacture, its installation, and its early operation were all borne by an enthusiastic but small band of workers having an almost idolatrous belief in their chief as the pioneer of this great industry.

I have brought with me to-night a photograph of the original direct connected steam generator known as the "Jumbo" machine, used in the Pearl street station, composed of an engine manufactured by Armington & Sims, of Providence, R. I., of the single cylinder type, running at a speed of 350 revolutions, with what is practically the old form of Edison bipolar machine changed from a vertical to a horizontal position, the armature instead of being wound with coils of wire, being built up of copper discs and bars. If you will glance from this to the picture of a modern central station unit composed of a compound, triple, or quadruple expansion engine, with a multipolar dynamo connected directly on the engine shaft, you will find that the same broad engineering idea is alike apparent in the earliest and latest central station unit. The improvements in dynamo manufacture have enabled us to use lower speed engines, but the broad principle of direct connection is alike the same in both. That we should come back to exactly what Mr. Edison used in the earliest central station work is no mean tribute to him as an engineering authority.

The delay which necessarily occurs in carrying every new enterprise to a financial success acted as a wet blanket on central station development. Efforts were made to cheapen construction when it was found that capitalists in large cities were unprepared to risk their money in the enterprise. The apparatus was adapted to the requirements of smaller communities, and, as a result, a number of small stations were established throughout the country, especially in Pennsylvania, Ohio and Massachusetts. The development of the central station business for several years was confined to this class of work. The service was far from reliable, owing mainly to the necessity of doing the cheapest possible engineering and construction in order to meet the necessities of the slim exchequers of those who were bold enough to embark their capital in this business; but the Pearl street station, started on September 5, 1882, with 5,500 lamps, rapidly developed, and in the fourteenth month of continuous running had 508 customers, wired for 12,732 lamps. Comparatively little work was done in central station lighting in Europe. A small station was started in Dijon, France, in June, 1883, and in the same year an installation was made in Santiago, Chile; in Milan, Italy; on Holborn Viaduct, London, and in Manchester.

The success of the Pearl street station resulted in the extension of the New York system and the building of two stations uptown in New York, one in Twenty-sixth street, and the other in Thirty-ninth street. This was followed by a station in Boston and another in Brooklyn. In 1887 the building of the first station in Chicago was started, the average load, as shown by the composite ampere curves of that station, which I have with me, being not much over 500 amperes for the year 1888. These

[1]Through the courtesy of Mr. Insull and of the Purdue University, we are able to present our readers with the text of a lecture delivered on May 17, before the School of Electrical Engineering at Lafayette, Ind. An illustrated edition of the lecture will be published by the University.

latter stations, the two in New York, the one in Boston and the one in Chicago were equipped with high speed engines belted to Edison bipolar dynamos of the Siemens armature type, in some cases the engines and dynamos being on the same floor, in other cases the engines being belted to the dynamos on the floor above. Numerous other stations were started, so that by 1890 upwards of sixty cities were equipped with the direct current low tension system, all of which, and numerous others, are to-day so remunerative that their securities are considered among the most desirable local investments, especially in cities of the first and second rank.

The success of the low tension system was followed by the introduction of the alternating system, using high potential primaries with the converters at each house, reducing, as a rule, from 1,000 down to either 50 or 100 volts. I am not familiar with the early alternating work, and had not, at my disposal, sufficient time in preparing my notes to go at any length into an investigation of this branch of the subject; nor do I think that any particular advantage could have been served by my doing so, as it has become generally recognized that the early alternating work with a house-to-house converter system, whilst it undoubtedly helped central station development at the time, proved very uneconomical in operation and expensive in investment, when the cost of converters is added to the cost of distribution. The large alternating stations in this country have so clearly demonstrated this that their responsible managers have, within the last few years, done everything possible, by the adoption of block converters and three-wire secondary circuits, to bring their system as close as they could in practice to the low-tension direct-current distribution system. I do not want to be understood as undervaluing the position of the alternating current in central station work. It has its place, but to my mind its position is a false one, when it is used for house-to-house distribution with converters for each customer. The success of the oldest stations in this country, and the demonstration of the possibilities of covering areas of several miles in extent by the use of the three-wire system, resulted in much capital going into the business. One of the earliest stations of a really modern type installed on either side of the Atlantic, was built by the Berlin Electricity Works. The engineers of that station, while recognizing the high value of the distributing system, went back to Edison's original scheme of a compact direct connected steam and electric generator, but with dynamos of the multipolar type designed and built by Siemens & Halske, of Berlin, the engines being of vertical marine type.

This was followed by the projecting in New York of the present Duane street station, employing boilers of 200 pounds pressure, triple and quadruple expansion engines of the marine type, and direct connected multipolar dynamos. Almost immediately thereafter, the station in Atlantic avenue, Boston, somewhat on the same general design so far as contents is concerned, was erected. In 1891 a small station, but on the same lines, was projected for San Francisco, and in 1892 the present Harrison street station of the Chicago Edison Company was designed, and benefiting by the experience of Berlin, New York and Boston, this station produces electric current for lighting purposes probably cheaper than any station of a similar size anywhere in this country.

It is not necessary for me to go into detail in explanation of the modern central station. You are all doubtless quite familiar with the general design, but if you will examine the detail drawings of the Harrison street station, which I have brought with me, you will find that every effort has been made to provide for the economical production of steam, low cost of operating, good facilities for repairs and consequently low cost, and for permanency of service. You have but to go into any of the modern central stations in midwinter, to see them turning out anywhere from 10,000 to 30,000 amperes with a minimum of labor, to appreciate the fact that central station business is of a permanent and lucrative character.

To go back to the question of alternating currents, the work done in connection with the two-phase and three-phase currents and the perfection of the rotary transformer has resulted in introducing into central station practice a further means of economizing the cost of production—by concentration of power. According to present experience, it is (except in some extraordinary cases) uneconomical to distribute direct low tension current over more than a radius of a mile and a half from the generating point. The possibility of transmitting it at a very high voltage, and consequently low investment in conductors, has resulted in the adoption of a scheme, in many of the large cities, of alternating transmission combined with low tension distribution. The limit to which this alternating transmission can be economically carried has not yet been definitely settled, but it is quite possible even now to transmit economically, from the centre of any of our large cities to the distant suburbs, by means of high potential alternating currents, distributing the current from the sub-centre of distribution by means either of the alternating current itself and large transformers for a block or district, or else if the territory is thickly settled, by means of a system of low tension mains and feeders, the direct current for this purpose being obtained through the agency of rotary transformers.

There are various methods of producing the alternating current for transmission purposes. In some cases the generators are themselves wound for high potential; in others they are wound for eighty volts, and step-up transformers are used, carrying the current up to whatever pressure is desired, from 1,000 to 10,000 volts. In other cases, dynamos are used having collector rings for alternating current on one side and a commutator for direct current on the other side of the armature, thus enabling you, when the peak in two districts of a city comes at two different times, to take care of this peak by means of the same original generating unit, furnishing direct low tension current to the points near the central station, and alternating current to the distant points. In other cases, where a small amount of alternating current is required on the transmission line, it has even been found economical to take direct current from a large unit, change it by means of a rotary transformer into alternating current, step up from 80 to, say, 2,000 volts, go to the distant point, and step down again to 80 volts alternating, and then convert again by means of a rotary transformer into a low potential direct current.

The introduction of alternating current for transmission purposes is probably best exemplified in large cities, in the station recently erected in Brooklyn, where alternating current is produced and carried to distant points, and then used to operate series arc light machines run by synchronous motors, the low tension direct current network being fed by rotary transformers, and alternating circuits arranged with block converters, and even in some cases separate converters for each individual customer in the scattered districts.

It would be very interesting to go at length into the details of cost in this, the latest development of central station transmission, but time will not permit, nor have I the time at my disposal to go at length into the central station business as developed by the electric street railways now so universally in use, or another phase of the business as exemplified by the large transmission plants, the two greatest examples of which, in this country, are probably those at Niagara Falls, N. Y., and Lachine Rapids, near Montreal. So far as street railways and power transmission are concerned, I would draw your attention to the fact that the same underlying principle of multiple-arc mains and feeders originally conceived by Mr. Edison is as much a necessity in their operation as it is in the electric lighting systems, whether those systems be operated on the old two-wire plan, the three-wire plan or by means of alternating currents.

Passing from a review of central station plants and distribution system naturally brings us to the operating cost and the factors governing profit and loss of the enterprise. In considering this branch of the subject, I will confine my remarks to the business as operated in Chicago by the company with which I am connected.

Our actual maximum last winter came on the 20th of December, our load being approximately 12,000 h. p. A comparison of the figures of maximum capacity and maximum load of last winter shows that we had a margin in capacity over output of about 20 per cent. The load curves shown this evening represent the maximum output of last winter (December 20), an average summer load last year (June 4), and an average spring load of this year (May 2). For our purposes we will assume the maximum capacity of the plant and the maximum load of the system to be identical. The maximum load last winter occurred, as I have stated, on December 20, about 4.30 o'clock in the afternoon, and lasted less than half an hour. It should be borne in mind that the period of maximum load only lasts for from two to three months, and that the investment necessary to take care of that maximum load has to be carried the whole year. It should not be assumed from this statement that the whole plant

as an earning factor is in use 25 per cent. of the year. The fact is that, during the period of maximum load, the total plant is in operation only about 100 hours out of the 8,760 hours of the year; so that you are compelled, in order to get interest on your investment, to earn the interest for the whole of the year in about 1½ per cent. of that period, on about 50 per cent. of your plant.

This statement must bring home to you a realization of the fact that by far the most serious problem of central station management, and by far the greatest item of cost of your product, is interest on the investment. It may be that the use of storage batteries in connection with large installations will modify this interest charge, but even allowing the highest efficiency and the lowest cost of maintenance ever claimed for a storage battery installation, the fact of high interest cost must continue to be the most important factor in calculating profit and loss. This brings home to us the fact that in his effort to show the greatest possible efficiency of his plant and distribution system, it is quite possible that the station manager may spend so much capital as to eat up many times over in interest charge the saving that he makes in direct operating expenses. It is a common mistake for the so-called expert to demonstrate to you that he has designed for you a plant of the highest possible efficiency, and at the same time for him to lose sight of the fact that he has saddled you with the highest possible amount of interest on account of excessive investment. Operating cost and interest cost should never be separated. One is as much a part of the cost of your current as the other. This is particularly illustrated in connection with the use of storage batteries. Those opposed to their use will point out to you that of the energy going into the storage battery only 70 per cent. is available for use on your distribution system. That statement in itself is correct; but in figuring the cost of energy for a class of business for which the storage battery is particularly adapted, the maximum load, that portion of your operating cost affected by the 30 per cent. loss of energy in the battery, forms under 4½ per cent. of your total cost, and it must be self-evident, in that case at least, that the 30 per cent. loss in the storage battery is hardly an appreciable factor in figuring the operating cost of your product. So far as I have been able to ascertain, it would appear to be economical to use storage batteries in connection with central station systems, the peak of whose load does not exceed from two to two and one-half hours.

In order to illustrate the important bearing which interest has on cost, I have prepared graphical representations of the cost of current, including interest under conditions of varying load factors. For the purpose of this chart I have assumed an average cost of current, so far as operating and repairs and renewals and general expense are concerned, extending over a period of a year, although of course these items are more or less affected by the character of the load factor. For the purpose of figuring interest, I have selected seven different classes of business commonly taken by electric light and power companies in any large city. Take, for instance, an office building. It has a load factor of about 3.7 per cent., that is, the average load for the whole year is 3.7 per cent. of the maximum demand on you for current at any one time during that period; or, to put it another way, this load factor of 3.7 per cent. would show that your investment is in use the equivalent of a little over 323 hours a year on this class of business. This is by no means an extreme case. You can find in almost every large city customers whose load factors are not nearly as favorable to the operating company, their use of your investment being as low as the equivalent of 75 or 100 hours a year. Take another class of business, that of the haberdasher, or small fancy goods store. As a rule these stores are comparatively small, with facilities for getting a large amount of natural light and little use for artificial light. The load factor as shown by the chart is about 7 per cent., the use of your investment being not quite twice as long as that of the office building. Day saloons show an average of 16 per cent. load factor; cafetiers and small lunch counters about 20 per cent., whilst the large dry goods stores, in which there is comparatively little light, have a load factor of 25 per cent., and use your investment seven times as long per year as the office building. Power business naturally shows a still better load factor, say 35 per cent., and the all-night restaurant has a load factor of 48 per cent.

You will see from this that the great desideratum of the central station system is, from the investors' point of view, the necessity of getting customers for your product whose business is of such a character as to call for a low maximum and long average use. This question of load factor is by all means the most important one in central station economy. If your maximum is very high and your average consumption very low, heavy interest charges will necessarily follow. The nearer you can bring your average to your maximum load the closer you approximate to the most economical conditions of production, and the lower you can afford to sell your current. Take, for instance, the summer and winter curves of the Chicago Edison Company. The curve of December 20, 1897, shows a load factor of about 48 per cent.; the curve of May 2, 1898, shows a load factor of nearly 60 per cent. Now, if we were able in Chicago to get business of such a character as would give us a curve of the same characteristics in December as the curve we get in May; or, in other words, if we could improve our load factor, our interest cost would be reduced, an effect would be produced upon the other items going to make up the cost of current, and we probably could make more money out of our customers at a lower price per unit than we get from them now.

Many schemes are employed for improving the load factor, or, in other words, to encourage a long use of central station product. Some companies adopt a plan of allowing certain stated discounts, providing the income per month of each lamp connected exceeds a given sum. The objection to this is that it limits the number of lamps connected. Other companies have what is known as the two-rate scheme, charging one rate for electricity during certain hours of the day and a lower rate for electricity used during the balance of the day, using a meter with two dials for this purpose. Other companies use an instrument which registers the maximum demand for the month, and the excess over the equivalent of a certain specified number of hours monthly in use of the maximum demand is sold at greatly reduced price. The last scheme would seem particularly equitable, as it results in what is practically an automatic scale of discounts based on the average load factor of the customers. It does not seem to be just that a man who only uses your investment, say, 100 hours a year, should be able to buy your product at precisely the same price as the man who uses your investment, say, 3,000 hours a year, when the amount of money invested to take care of either customer is precisely the same. Surely the customer who uses the product on an average thirty times longer than the customer using it for only 100 hours is entitled to a much lower unit rate, in view of the fact that the expense for interest to the company is in one case but a fraction per unit of output of what it is in the other. This fact is illustrated by the interest columns on the graphic chart already referred to. Supposing that the central station manager desired to sell his product at cost, that is, an amount sufficient to cover his operating, repairs, and renewals, general expense, and interest and depreciation, he would have to obtain from the customer having the poorest load factor, as shown on the load chart, over four times as much per unit of electricity as it would be necessary for him to collect from the customer having the largest load factor. No one would think of going to a bank to borrow money and expect to pay precisely the same total interest whether he required the money for one month or for twelve; and for the same reason it seems an absurdity to sell electricity to the customer who uses it but a comparatively few hours a year at the same price at which you would sell it to the customer using it ten hours a day and three hundred days a year, when it is remembered that interest is the largest factor in cost, and the total amount of interest is the same with a customer using it but a few hours a year as it is with the customer using it practically all the year around.

I have dwelt thus at length on the question of interest cost in operating a central station system, not alone for the purpose of pointing out to you its importance in connection with an electrical distribution system, but also to impress upon you its importance as a factor in cost, in fact, the most important factor in cost in any public service business which you may enter after leaving this institution. Most of the businesses presenting the greatest possibilities from the point of view of an engineering career, are those requiring very large investment and having a comparatively small turn-over or yearly income. Of necessity in all enterprises of this character, the main factor of cost is interest, and if you intend following engineering as a profession, my advice to you would be to learn first the value of money, or, to put it in another way, to learn the cost of money.

Before leaving this question of interest and its effect upon cost, I would draw your attention to the fact that while interest

is by far the most important factor of cost, it is a constantly reducing amount per unit of maximum output in practically every central station system. When a system is first installed, it is the rule to make large enough investment in real estate and buildings to take care of many times the output obtained in the first year or so of operation. As a rule the gererating plant from the boilers to the switchboard is designed with only sufficient surplus to last a year or so. In the case of the distributing system the same course is followed as in the case of real estate and buildings, with a view to minimizing the ultimate investment. Mains are laid along each block facing, feeders are put in having a capacity far beyond the necessity of the moment, consequently interest cost is very high when a plant first starts, except, as I have stated, in the case of the machinery forming the generating plant itself. As the business increases from year to year the item of interest per unit of maximum output consequently will constantly decrease, owing to the fact that each additional unit of output following an increase of connected load increases the divisor by which the total interest is divided. The result is from year to year the interest cost of each additional unit of maximum output is a constantly reducing amount, and consequently the average interest cost of each unit of maximum output should, in a well regulated plant, grow less from year to year until the minimum interest cost per unit is reached. This minimum interest cost is reached when the capacity of the whole system and the total units of output at maximum load are identical, although of course it will always be necessary to have a certain margin of capacity over possible output, as a factor of safety.

This same rule, although to a less extent, applies to the operating and general expense cost, that is, the cost other than interest. To particularize, the manager's salary and other administrative expenses do not increase in proportion to maximum output of station; therefore the cost of administration per unit of output, if the business is in a healthy condition, must be from year to year reduced. There are a great many other expenses that are not directly in proportion to output, and these follow the same rule. In a well-run plant the percentage of operating expenses to gross receipts will stand even year after year, whilst the income per unit of output will be constantly reduced. This is an excellent evidence of the fact that the cost per unit of output is constantly being reduced, as, if it were not, the percentage of expenses to gross receipts would be increased in direct proportion to the reduction in price.

Moreover, it should be borne in mind that there are many difficulties in the way of universal use of electric energy from a central station system. It is the rare exception to find a house not piped for gas and water. In the case of the latter it is almost invariably the rule that owners are compelled to pipe for water, under the sanitary code of the municipality. On the other hand, in a large residential district, it is the exception to find a house wired for electric light, consequently the output of current per foot of conductor is at the present time very low as compared with the output of gas per foot of gas pipe in any of the large cities. The expense of wiring (which must of necessity be borne by the householder) is large, and it is often a barrier to the adoption of electric illumination, but as the rule to wire houses becomes more general, the output per foot of main will constantly increase, and therefore the interest per unit of output per foot of main will constantly decrease. This same rule will apply in the case of expenses in taking care of and repairing the distribution system, although to not so great an extent.

If you will take into account these various factors constantly operating toward a reduction of operating and general expense cost, and interest cost, the conclusion must necessarily be forced upon you that the price at which current can be sold at a profit to-day is in no sense a measure of the income per unit which it will be necessary for central station managers to obtain in the future. In 1881-2 it was difficult to make both ends meet with an income of 25 cents per kilowatt hour; to-day there are many stations showing a substantial return on their investment, whose average income does not exceed 7 cents per kilowatt hour, showing 70 per cent. reduction in price in less than two decades. How far this constant reduction in cost, followed by a constant reduction in selling price, will go, it is difficult to determine; but if so much has been accomplished during the first twenty years of the existence of the industry, is it too much to predict that in a far less time than the succeeding twenty years electric current for all purposes will be within the reach of the smallest householder and the poorest citizen? But few industries can parallel the record already obtained. If you will trace the history of the introduction of gas as an illuminant you will find that it took a much longer time to establish it on a commercial basis than it has taken to establish most firmly the electric lighting industry. All the great improvements in gas, the introduction of water gas, the economizing in consumption by the use of the Welsbach burner, have all been made within the time of those before me, and yet, notwithstanding that when these gas improvements started the electric lighting business was hardly conceived, and certainly had not advanced to a point where you could claim that it had passed the experimental stage, notwithstanding this, the cost of electrical energy has decreased so rapidly that to-day there are many large central station plants making handsome returns on their investments at a far lower average income per unit of light than the income obtained by the gas company in the same community. In making my calculations which have led me to this conclusion, I have assumed that 10,000 watts are equal to 1,000 feet of gas. This comparison holds good, providing an incandescent lamp of high economy is used as against the ordinary gas burner. To make a comparison between electric illumination and incandescent gas burners, such as the Welsbach burner, you must figure on the use of an arc lamp in the electric ciruit instead of an incandescent lamp, which is certainly fair when it is remembered that incandescent gas burners are, as a rule, used in places where arc lamps should be used if electric illumination is employed.

With such brilliant results obtained in the past, the prospects of the central station industry are certainly most dazzling. Whilst the growth of the business has been phenomenal, more especially since 1890, I think it can be conservatively stated that we have scarcely entered upon the threshold of the development which may be expected in the future. In very few cities in the United States can you find that electric illumination exceeds more than 20 per cent. of the total artificial illumination for which the citizens pay. If this be the state of affairs in connection with the use of electricity for illuminating purposes, and if you will bear in mind the many other purposes to which electricity can be adapted throughout a city and supplied to customers in small quantities, you may get some faint conception of the possible consumption of electrical energy in the not far distant future. Methods of producing it may change, but these methods cannot possibly go into use unless their adoption is justified by saving in the cost of production, a saving which must be sufficient to show a profit above the interest and depreciation on the new plant employed. It is within the realms of possibility that the present form of generating station may be entirely dispensed with. It has already been demonstrated experimentally that electrical energy may be produced direct from the coal itself without the intervention of the boiler, engine and dynamo machine. Whether this can be done commercially remains to be proved. Whatever changes may take place in generating methods, I should, were I not engaged in a business which affords so many remarkable surprises, be inclined to question the possibility of any further material change in the distributing system. Improvements in the translating devices, such as lamps, may add enormously to the capacity of the distributing system per unit of light; but it does seem to me that the system itself, as originally conceived, is to a large extent a permanency. Should any great improvements take place in the medium employed for turning electrical energy into light, the possible effect on cost, and consequently selling price, would be enormous.

The 220 Volt Lamp in Practice.

BY J. C. FISH.

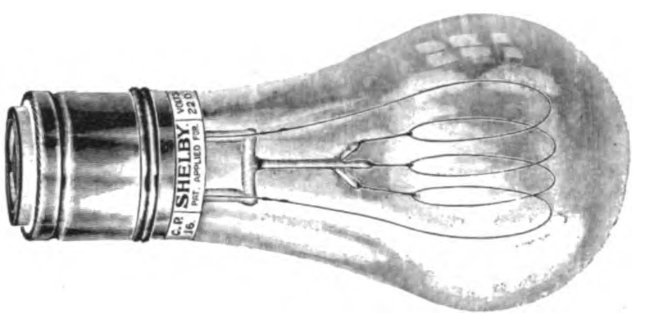
WE have been interested in an article which appears in the current issue of your valuable journal, on page 487, entitled "English Experience with 220 Volt Lamps," which points out the difficulties experienced in the use of lamps of high voltage, as discovered and experienced by Mr. Binswanger Byng, and described by him in a paper read before the London Institution of Electrical Engineers.

It is true that the lamp manufacturers in all parts of the world have been compelled, in order to meet the wishes of their trade, to supply 220 volt lamps at given candle powers in bulbs which should not be noticeably different from the bulbs used in the ordinary 110 volt lamp. The difficulties as shown by Mr. Byng are difficulties that have made it to a degree unsatisfactory to make high voltage lamps. The Shelby Electric Co., however, have secured patents on a type of lamp which permits them to use a

flashed carbon, made in the manner that is in certain respects different from other carbons and still permit it to be stowed away in the small bulb. This company is treating or flashing all of the filaments they use in 220 volt lamps, and consequently they get a much more even result at higher efficiency and less drop in candle power than it has been possible to attain when making lamps under the old principles.

A reference has been made to tests made by Mr. Robertson, which show that the unflashed carbon loses in candle power about 42 per cent., and in efficiency about 35 per cent. Tests made by The Shelby Electric Co. on various makes of 220 volt lamps substantiate the statements made by Mr. Robertson, and tests made on the treated carbons used by this company show that a lamp of 220 volts can be made that will give just as good satisfaction in regard to life, efficiency and maintenance of candle power as it is possible to obtain with any lamp of 110 volts

The accompanying engraving illustrates how the "Shelby" lamp is made, showing that the disadvantages, as stated in the article referred to, although conceded to be general, have been overcome by the Shelby Company. The separation between the leading-in wires is in excess of ½ inch, and thus the difficulty



SHELBY 220-VOLT LAMP.

referred to by Mr. Byng as a vital one, is overcome. Electrostatic effects which Mr, Byng truthfully stated increased with the voltage, have also been overcome by insulating the leading-in wires throughout, and consequently the "Edison effect or leakage current," which leads to short circuiting, is entirely overcome.

In the tests made by The Shelby Electric Company it has been demonstrated very thoroughly that a paste connection or deposit of paste on the anchors, can not be satisfactorily used in a high voltage lamp, as the carbon is necessarily so thin that the least amount of oxygen permitted to enter the lamp will certainly destroy it. This has also necessitated the use of platinum wire for anchors. A 220 volt lamp must be made in a manner that provides for all of the disadvantages as set forth in Mr. Byng's paper, but as the Shelby lamps embody principles by which all of these disadvantages have been overcome, we think it is not fair to say that 220 volt lamps are not a success.

The Shelby Electric Co., it may be added, have produced for experimental purposes, a number of 500 volt lamps, and they claim that patents which they have covering the manner of making these lamps will protect them from being met in competition should the time ever come when a 500 volt lamp should be needed.

Large Power Transmission Plant in Mexico.

The Westinghouse Electric and Manufacturing Company has closed a contract for twenty 300 h. p. two-phase generators, with switchboard and raising transformers, for the San Ildefonso-Tlalnepantla Transmission system, near the City of Mexico. The current is to be utilized for lighting and power in the city. The generators are to be direct-connected to water wheels. Transmission will be three-phase at 32,000 volts. The terms of the contract call for its completion by March 1, 1899. The introduction of so large an installation of American apparatus marks a long step forward in the electrical development of the abundant sources of water power in Mexico.

THE SPANISH SKETCHES by Pierre Loti, which "The Living Age" is printing in an excellent translation made for its pages by William Marchant, exhibit the picturesque descriptive powers of that charming writer at their best. One sketch in the first group gives a glimpse of the Queen Regent of Spain.

TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work.—XII.

BY A. E. DOBBS.

CABLE TERMINALS.

OF course all cables must have means for connecting the cable conductors to the lines outside or in some cases changing conductors from one cable to another.

There are only about two or three forms of cable terminals in common use, and one of the oldest of these is shown in Fig. 37.

In this terminal the top, front and back are made of hardwood, the two sides, D, being usually constructed of hard rubber,

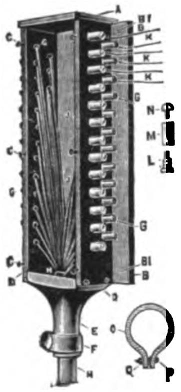


FIG. 37.

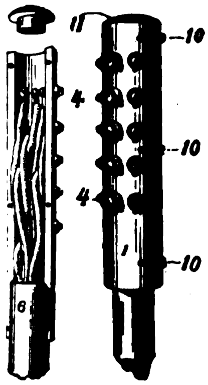

FIGS. 38 AND 38a.

in which are mounted the binding posts, c, by means of which a moisture-proof connection is established. The terminal is fastened against the back of the cable box, the end of the cable is

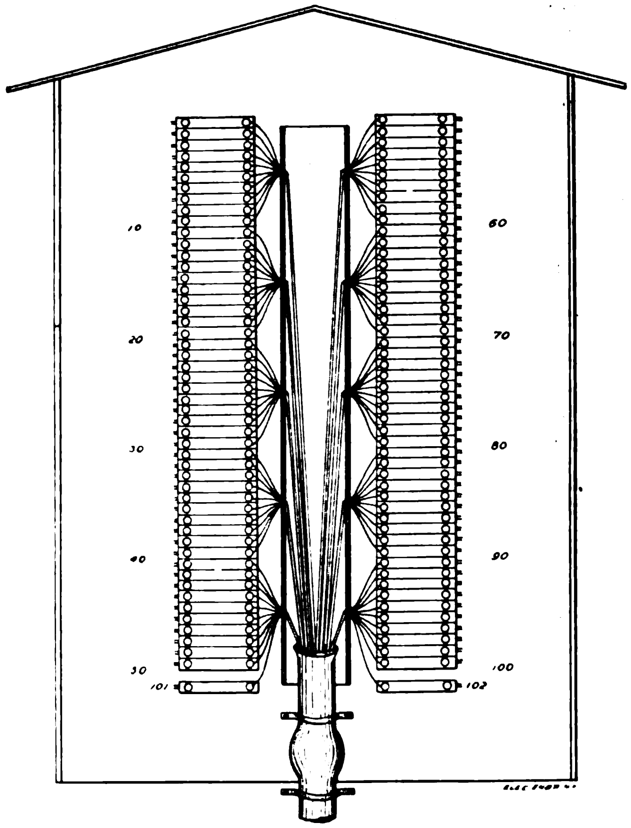

FIG. 39.

passed through the grip, E, and held there by the band, F (this can be soldered by a wiped joint if preferred). The cable conductors are then spread out, the necessary amount of insulation

[1]Figs. 37 and 38 are reproduced by permission from the handbook of the Standard Underground Cable Co., Pittsburg, Pa.

stripped off, and the wire passed through the back of binding post, which is shown in detail at L, M, U, and thus connection made to the wires outside.

Another form of this cable is simply a cast-iron box, with the back, sides, top and bottom in one piece, and the front in another, with a thin soft rubber strip underneath to make the joint airtight, the binding-posts being bushed with hard rubber. This is a very strong and substantial head. In both these forms it is common to fill part or all of the head with insulating compound poured in hot. The wires are frequently soldered to the binding-posts on the inside.

The tubular terminal (Figs. 38 and 38a) is considerably cheaper than the above mentioned, and its simplicity, lightness, and the small space it occupies, makes it very popular in many places.

It is composed of three parts; a split tube and a cap. One of these parts contains the binding posts, which after the end of the cable is stripped back is fitted down over it up nearly to the bottom posts. Alongside of each binding screw is a small hole in the rubber tube, through which the wire is pushed and connected to the lower part of the post outside, instead of inside the terminal, the line wire being fastened to the upper part.

After all these connections are made, the other half of the tube is fitted on and held in place by screws, and an insulating compound such as ozite or a mixture of rosin and beeswax is poured in until full, and the cap fitted on while it is still warm, thus sealing it up tight. Note—In pouring these compounds into the cable keep them hot till all air bubbles cease to rise, for then only is all dampness removed.

Fig. 39 shows a design by the writer, which, however, is not new. The cable is stripped back from the end as in making a cable joint; rubber insulated wire is then connected and soldered to the paper covered conductors, the wires being long enough to reach the binding posts. A lead sleeve is then slipped on long enough to cover all the joints, with room to spare, after which

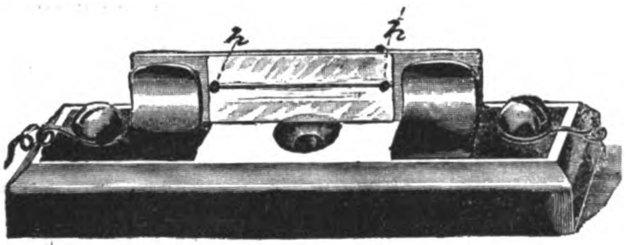

FIG. 40.

the sleeve is soldered on with a wiped joint and filled full and running over with hot insulating compound, which must be of a nature that will harden when cool.

The wires are distributed by means of two parallel wooden strips set up on edge and fastened to the back of the box, the wires being distributed directly to the line terminals without the intervention of binding posts.

These wooden strips, after all holes are bored, should be plunged into boiling paraffine, or thoroughly coated with P. & B. paint, though ordinary asphaltum or shellac will answer.

For convenience in counting, the wires in the illustration are divided into groups of 10 each. A ⅜-inch hole will generally be big enough for 10 wires.

COUNTING TERMINALS, ETC.

The system of connecting and numbering the posts on cable terminals should be uniform throughout the plant, the following being the usual way. For terminal posts on the side, Fig. 37.

Left Side.	Right Side.
●——— 1	●——— 51
●—— 2	●—— 52
●——— 3	●——— 53
●—— 4	●—— 54
●——— 5	●——— 55
●—— 6	●—— 56

It will be observed that most of these terminals are fitted up with 102 or 104 posts, in which case it is better to have the 26th post on each row regarded as an extra and called 101 and 102 respectively; this keeps the rows in multiples of 25 and facilitates counting, the same idea being shown in Fig. 39.

With tubular and some cast-iron terminals with four rows of posts down the front, the counting begins at the left hand row, and counts straight downward, except as to the 26th and 101st posts, which are left for 101 and 102, thus keeping each row ending on some multiple of 25. Follow a systematic method in keeping the pairs together, as 1—2, 3—4, 5—6, or 1 to 51, 2—52, 3—53, etc.; then if necessary to use metallic circuits, the pairs can be easily found and kept together.

In many places where cables are comparatively short, as at office poles, one side of each pair is connected to a bus-bar in the box, which is connected to the common return wire, thus keeping each circuit separate and full metallic out to the box, then, if a metallic circuit is needed, the conductor is simply disconnected from the bus-bar and connected directly through. This method is very much used in the latest work now being done. It has the merit of preventing a great deal of cross talk in the office end of the lines. With a paired cable there will be a tendency towards cross talk if the pair is run as two

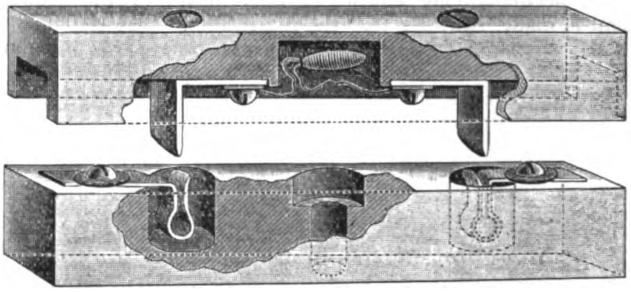

FIG. 41.

single lines, although it should be confined to those two only, if the cable is all right otherwise.

Speaking of those mixtures of rosin, beeswax and paraffine, I have not given the proportions of each because they have to be changed to suit the different conditions. In cable heads, for instance, harden by putting in more rosin, while on cable joints they should be soft. A few minutes experimenting will give the right proportion.

FUSES AND LIGHTNING ARRESTERS.

Fuses are used to open the circuit in case there is an excess of current on the line which might destroy the instruments. The best and most convenient types of fuses I know of are those shown

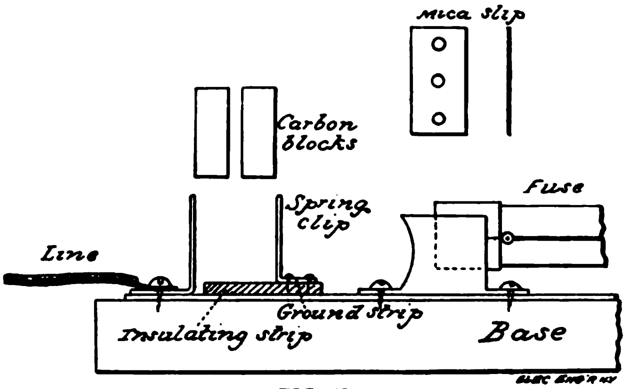

FIG. 42.

in Figs. 40 and 41. In Fig. 40 it is merely a mica strip, with thin sheet copper bent around the ends to which the fuse is soldered. There are two holes in the mica, h, h', which are designed to let two or three turns be taken back and forth, the fuse, of course, being insulated with a cotton or silk covering, and provides a greater safety factor by having about six or eight inches of length instead of three. Or, if lead fuse wire is used, it may be wound around the outside of the mica two or three times to obtain the same result.

Fig. 41 has insulated fuse wire done up in a coil to increase the length and also to furnish a spot not surrounded by free air so that the fuse will go quicker.

Both the above forms are very convenient in testing, as the clip has only to be pulled out to open the line. Another form which has found favor in many places, especially with the underwriters, consists of a spring strip held down by the fuse wire. As long as the fuse is in good condition the strip will stay down, but should it become opened the spring flies up, throwing the two ends far apart, thus preventing the arc which often follows the

destruction of a fuse. Even if highly heated, the tension on the spring will break the fuse and cut it out anyhow.

But forms, Figs. 40 and 41, are almost as free from arcing and just as reliable on account of their greater length of fuse wire, and when mounted on porcelain blocks an arc, on a half ampere fuse, cannot be very dangerous.

In order to protect the switchboard, the fuses should melt with any current above half an ampere within a reasonable length of time, say, five or six seconds. The easiest way to test this if an ammeter is not handy, is to take a 110 volt lamp, an old one that has burned 600 hours or more, which will pass from .60 to .75 of an ampere; connect the fuse in circuit, and if it doesn't go in five seconds don't use it. If a 110 volt current cannot be had, use one of 50 volts, but with a new lamp, and, as a 50 to 55 volt lamp takes about one ampere of current, the fuse should melt right away in not more than one or two seconds.

In writing to manufacturers of fuse wire, be sure to state the highest limit of the current which it is desired the fuse shall carry, and also the length of fuse used, for a fuse two inches long will carry at least twice as much current as one six inches in length.

Fuses made of lead wire are apt to increase in their heat carrying capacity, and a fuse wire which when new, will blow at half an ampere, may stand one ampere after being in place a few months; on this account some managers insist upon having them shellaced as soon as they are made up, to prevent the action of the air. German silver, aluminum or copper, make the most reliable fuses. In Fig. 42 is shown a form of lightning arrester, combined with a fuse, which explains itself. A pair of carbon blocks, one connected to the ground plate by a spring clip, and the other connected to line the same way, a thin strip of mica holding them apart. The mica has two or three holes punched through the centre, and the air in these holes being nearly all expelled as soon as the discharge takes place, it will in this way offer a path of low resistance to ground as long as the current remains on the line, while the absence of air at these points prevents the carbon from burning up. Carbon does not corrode nor fuse, and as long as it lasts it is always ready for business. There are several forms of lightning arresters made on this principle, and they constitute the most efficient class I know of.

As to the necessity for fuses and lightning arresters in cable boxes, practice differs greatly. In some parts of the United States, as on the Pacific coast, lightning arresters are not considered necessary, and the only safeguard is a fuse placed behind the switchboard to protect it against trolley or electric light currents, while in some of the Southern States too many safeguards cannot be used, and even then lightning will sometimes go by them all.

When lightning gets into the cable over a single conductor, the static and inductive resistance of the cable sheath, and the other conductors, especially the one it is paired with, makes a condition that is very liable to break down the insulation between them. If, however, lightning arresters are placed in the terminal box, it will either flash to ground or become so divided among the various conductors as to be practically harmless. Even where there are no arresters it will generally spread more or less over all the terminal binding posts.

It is, I think, an open question whether fuses are much of a protection against lightning, for when it has come several feet through the air for the express purpose of visiting an exchange, it will not be stopped by two or three inches of fuse, and before the fuse can possibly cut out the lightning has gone by and the line has been opened without being afforded any protection.

On the whole I think that the best place for fuses is behind the board or in the cross connecting room, where they can be readily inspected and replaced, and if the insulation of the cable is up to standard the only effect of a trolley current will be to blow the fuse and make the cable noisy, till some one can go out and remove the cause of the trouble. But where lightning is to be feared I would put lightning arresters in the cable box, but without the fuse, for it will have to come fast and furious if the static induction of the cable will not shunt it to the ground strip, but to make sure it would be well to use these arresters in the exchange also. Where a metallic circuit, or common return system is used, it is a good idea to connect the middle or ground post of the subscriber's instrument, to ground the toothed plates generally affording sufficient protection.

In some cities where Underwriters' rules are strictly enforced, the company may be compelled to place a fuse block where the wires enter the subscriber's premises. In that case use a 1 ampere fuse, for one doesn't want a fuse to give way for every little thing that comes along. The inspector may also require porcelain or glass tubes where the wires enter the building.

In concluding I can lay down a few general rules which will produce the most satisfactory results, though they are not to be taken as conclusive.

1. Place lightning arresters with ground strip both in the cable box and in the exchange. If the return wire is grounded or connected to the lead sheath of the cable, connect the ground strip to it by a wire not smaller than No. 10 B. & S. G., or if the common return is not grounded, connect the ground strip of the arrester by a No. 6 wire to ground at the foot of the pole. It does not matter so far as lightning is concerned whether this ground wire is iron or copper, for Dr. Lodge's experiments would seem to show that possibly iron or steel is even better than copper.

2. If the cable boxes are easily reached and inspected from the exchange, place fuses there; if not, place them behind the cross connecting board. Too many fuses in a circuit are a source of annoyance, and it is better to have a drop burned out occasionally than to have a constantly interrupted service.

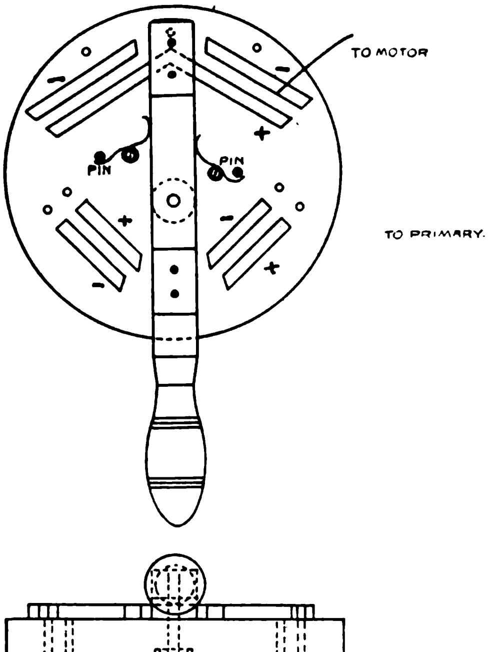
3. If the common return is not grounded, a large lightning arrester something like the Wurts non-arcing arrester, made by the Westinghouse Elec. Co., or the street railway arresters made by the General Electric Co., will be found best adapted to this work. As an additional precaution in this case, it would be well to have a switch connected to a ground wire, so that in a thuuderstorm the ground could be thrown in.

ROENTGEN RAYS

A New X-Ray Switch.

BY F. S. KOLLE, M. D.

IN The Electrical Engineer of Dec. 9, 1897, appeared a description of a double current switch for X-ray work devised by me for the purpose of controlling the currents of the motor make and break arrangement and the primary to the coil; but owing to the fact that the current going to the primary could not be reversed without practically making a duplicate of itself, to serve in that way, and owing to the statement



THE KOLLE X-RAY SWITCH.

of Mr. E. Willyoung in The Engineer of Dec. 30, 1897, in which he says, "There is danger of closing both circuits too nearly together," I devised the following new contact switch to over-

come all difficulties. The diagram herewith reproduced was completed January 12, 1898, but owing to the many demands made upon me in medico-surgical radiography, I have failed to write up the matter.

The switch is both simple and economic, being much cheaper than my former "jack-knife" device, and only on account of its great simplicity of construction do I deem it of sufficient merit to dwell upon it at all.

The base and handle are made of fibre, the clips of brass or copper, and the contact metal of brass sheeting. A spring washer guarantees sufficient pressure in making current; a metal or hard rubber cover would be a valuable addition. The handle is so placed, eccentrically, that the current of the motor can, and is, first thrown in. A small pin, placed, as shown, stops the handle from being crowded over too far. A German silver wire spring is so fixed on either side of handle bar as to produce sufficient counterforce to prevent closing both circuits too suddenly; but this is obvious when the operator is sensible enough to know the difference between handling a switch and a crow bar. However, to overcome objections it may be employed. By throwing the handle from side to side, the current to the primary is reversed at will.

Current Transformers.—II.

BY CHARLES T. CHILD

THE rotary converter, rotary transformer, or "rotary," as it is variously called, is a machine in all respects similar to a direct current dynamo, except that its armature winding is tapped at appropriate equidistant points and connected to collector rings. Alternating currents of the proper phase relation and frequency supplied to these drive the armature as a motor, direct currents being taken off by the commutator brushes exactly as if the machine were driven by an external source of power. But the current thus obtained cannot be regarded as generated in the armature. If the armature is driven at the speed at which it runs as a synchronous motor by an outside power, alternating currents, similar in phase and frequency to those supplying it, will be generated in it and rectified by the commutator. When the machine is supplied with such currents from an external source a small portion of the energy is utilized in turning the armature while the greater part of it is rectified at the commutator and flows out into the circuit as direct current.

The reactions taking place in the armature of a rotary transformer are of considerable complexity. By proper manipulation of the field strength the power factor may be made unity, or the machine may impress leading or lagging currents on the line like any other synchronous motor. The direct current voltage is dependent upon that of the alternating current and hence, in most cases, it is necessary to use stationary transformers to reduce the alternating line voltage to a proper value for the supply of a given direct voltage. Varying the field strength does not produce a corresponding variation of the voltage of the direct current side of the machine, but introduces modifications of the phase relations between current and e. m. f. in the alternating circuit which may be very troublesome. Generally speaking, the field strength must be governed by considerations of the alternating current supply line for the best results.

The allowable output of a rotary transformer is dependent not only upon its size, but as well upon the character of the supply current, whether this is single-phase, three-phase, quarter-phase, etc. It may be shown that the ratio of the C^2R losses in a given rotary to those that would be experienced if the machine were driven at the same output as a direct current dynamo is:

$$\frac{8}{n^2 \sin^2 \frac{\pi}{n}} + 1 - \frac{16}{\pi^2} + \frac{4}{n} \tan^2 \beta$$

where n is the number of equidistant points in the armature winding connected to the collector rings (in a bi-polar machine) or simply the number of rings, and β the angular value of the phase displacement between current and e. m. f. on the alternating side. Assuming the phase displacement to be zero, this gives as the "rating" of rotaries in terms of their performance as direct current dynamos the following figures[2]:

Single-phase.	Three-phase.	(Two-phase.) (Quarter-phase.)	Six-phase.
0.85	1.34	1.64	1.96

From this it is at once evident that the quarter-phase rotary for a given output may be made smaller than the three-phase machine and much smaller than the single-phase machine. Indeed the single-phase rotary, unless the current and e. m. f. on the alternating side are kept very closely in step with each other, is very inefficient and wastes much energy in heating loss.

The efficiency of a polyphase rotary is very high, higher indeed than that of the corresponding direct current dynamo, but this figure is deceptive since, on account of the interdependence of the currents and voltages on its two sides, stationary transformers are always needed in transmission work and the losses in these should be figured in addition to those in the rotary.

Since any variation in the voltage of the alternating current supply is immediately manifest at the direct side of the machine it is not so useful for work requiring close regulation as the motor-dynamo described above, but finds its principal field of usefulness in railway and electrolytic work. In it, as in the double-winding machine, the question of frequency enters and, in large sizes, considerations of speed, etc., practically limit this to 30 or 40 cycles per second. The high efficiency and complete reversibility of these machines make them peculiarly applicable for steadying the voltage of a polyphase system of supply when used in connection with a storage battery. In this way an alternating current system may partake of the hitherto distinguishing advantage of a direct current system, a steadying arrangement of this sort having been recently installed in one of the finest lighting central station systems in the world[3].

As compared with the motor-dynamo combination the rotary transformer possesses the great advantages of high efficiency, cheapness and simplicity. It is also self-starting on the alternating side, running up to synchronism without difficulty. Its disadvantages are the interdependence of the alternating and direct current voltages and the very limited range of adjustment of the latter. These, however, are by no means serious in railway work or in heavy electrolytic work, and in these directions the rotary has proved itself invaluable.

A type of this machine, miscalled the "induction rotary," has been used to a limited extent, the peculiarity of the machine being that it is not provided with field windings, the field magnetization being due to armature reaction from the lagging current. As the heating effect of lagging currents increases with the square of the tangent of the angle of lag it is evident that such machines cannot be as efficient as those in which the power factor can be maintained at unity, nor can they be of as large output per unit of weight. In addition to these defects, this type sacrifices the valuable control of the phase relations of the alternating system inherent in the usual form.

It is evident from an inspection of the table and formula given above that the output of a given machine will increase or, what is the same thing, that the heating loss will decrease and the efficiency improve as the number of collector rings or number of phases of the supplying current becomes greater. The very interesting transformer of MM. Hutin and Leblanc takes advantage of this fact and, while its mechanical complexity is very great and has limited its use, this type of rotary possesses none the less great electrical interest.

If, in a single-phase stationary transformer of which the primary coil is carrying an alternating current, the number of turns of the secondary connected to a given circuit can be varied synchronously with the current and according to a sine law, the potential at the terminals of the circuit may be kept constant and a direct current will flow in it. It is upon this principle that the "panchahuteur" works. It consists of a polyphase transformer of which the secondaries are divided into equal numbers of equal coils, these being grouped together and connected to brushes bearing upon an equal number of collector rings on the rotating shaft of the machine. This shaft also car-

[2]Woodbridge and Child, The Electrical World, Jan. 1 and Feb. 12, 1898. C. P. Steinmetz, Elektrotechnische Zeitschrift, March 3 and 10, 1898.

[3]See "The Edison Electric Illuminating Co., of Brooklyn," by Jos. Wetzler, The Electrical Engineer, January 6, 1898.

ries an armature and its commutator, the number of segements in the commutator being the same as the number of collector rings and one ring being connected to each segment. The armature turns in a proper field as a synchronous motor, and the currents from the secondaries flowing through the rings to the commutator are taken off by brushes as direct current. The machine is thus a rotary converter in which currents of many phases are transformed, the rotating armature of the usual type being replaced in part by the divided secondaries, which properly distribute the currents, and in part by the small motor armature, which gives the necessary rotation. The efficiency of the machine is very high and its output for size and weight remarkably large.

For phase transformations a number of more or less simple methods are in use. If an iron ring is wound with a continuous coil tapped at four equidistant points and these points connected to a quarter-phase circuit, then a three-phase current may be withdrawn from three equidistant points and, in general, n-phase currents may be taken from n equidistant points. This apparatus is perfectly reversible, the essential feature being the establishment of a rotating polarization of the ring. The Scott system for transforming between quarter-phase and three-phase currents (which is installed as a part of the Niagara transmission referred to above) uses two stationary transformers, of which the terminal of the secondary of one is connected to the middle of the secondary of the other. By properly proportioning the windings of the two secondaries a three-phase current may be withdrawn from the three free ends of the secondaries when the primaries are connected to a quarter-phase source.

A great desideratum has been to obtain a simple means for deriving polyphase currents from a single-phase source of supply. It was an early suggestion to pass a single-phase current through a divided circuit, of which the inductance of the two branches differed widely, thus causing a lagging of phase in the more inductive branch. An improvement upon this method consists in the use of a condenser in the path of less inductance giving rise to a leading phase and further separating the elements of current. These methods work well with small currents, but considerations of cost and the incident waste of energy prohibit their use for large powers.

The phase separating system of Ferraris and Arno, for deriving polyphase from single-phase currents, is very ingenious. It consists of two coils mounted as in the stator of a polyphase induction motor, one of them being the primary and connected to the single-phase circuit. A short-circuited rotor completes the apparatus. When this is running as a single-phase induction motor a single-phase current, displaced in phase from that in the primary by an amount equal to the angular separation of the two coils, will flow in the second coil, and the combination of this with the original single-phase current gives three-phase or quarter-phase current, according to the position of the second coil.

From the descriptions of the various methods of current transformation it is evident that each has its particular field of usefulness and that none can be selected as the best unless all the conditions of its service are known. For arc lighting the simple rectifier seems well suited, not only on account of the efficiency of the apparatus, but as well because of its simplicity and small size. A rectifier, however, requires as much attention as a dynamo, and in a recent fine installation three-phase synchronous motors are used coupled to ordinary direct current arc machines in preference to them. For heavy work, such as electrolysis and electric traction, where the conditions do not require close regulation of voltage, the rotary transformer is pre-eminent, as it is also in regulation work in connection with a storage battery. Where the alternating current is single-phase or where the requirements necessitate accurate regulation or a variable voltage at the direct current side, the motor-dynamo combination seems best fitted for the work. The interesting machine of Hutin and Leblanc appears also to have qualities that make it well worth further development and simplification.

THE RAILWAY TELEGRAPH SUPERINTENDENTS are to meet in Omaha on June 15.

MR. C. J. GLIDDEN has now become president of the Erie Telephone and Telegraph Co., with which he has so long and brilliantly been connected.

ELECTRIC TRANSPORTATION

The Selection of Proper Speed for Railway Motor Equipments.

BY J. R. CRAVATH.

THE equipment of an electric road is a series of selections from start to finish, selection of material, selection of types of apparatus, and selection of the practice to be adopted in operation. Among the many questions that are apt to be lost sight of when purchasing motors for an electric road is that of the proper speed of motors, and by this I mean the maximum speed at which the motors will run, as well as the schedule speed for which they are intended. It is very often the case that in selecting high speed motors the purchasers are acting on the adage that speed is a good thing, therefore "while your a gittin' git a plenty." The result of this policy has been to handicap numerous roads with motors which are much too fast for the service, resulting in excessive repairs and an unnecessary consumption of power. It may sound strange, but it is true that one set of motors may take twice the current and heat twice as badly in maintaining a given schedule as another set of motors geared lower but of the same dimensions otherwise. This of course is a rather extreme case, but it is not far from some conditions which exist in actual practice to-day. The reason for this may be more apparent after thoroughly understanding the following principles:

1. To produce a given torque or acceleration, the current required varies directly according to the maximum speed for which a motor equipment is geared.

2. The heating of a motor (C^2R) producing a given torque or acceleration varies directly as the maximum speed for which a motor is geared.

When it is remembered that in nearly all classes of electric railway service the principal work done by the motors is acceleration, it will be seen how important it is to select a motor of a speed which will give a high torque per ampere of current. These principles applied in practice mean that it will take twice as much energy to get a car up to a speed of 20 miles an hour if equipped with motors geared to 40 miles an hour, as it will to get the same car up to 20 miles an hour if it is equipped with 20 mile an hour motors, the rate of acceleration being the same in both cases. Furthermore, the 40 mile motors will heat twice as much as the 20 mile equipments during the process. Of course the higher speed equipments can be made to maintain a much faster schedule than the slower provided there is enough traction on the rails to permit of a faster acceleration or provided there is distance enough between stations to admit of a higher maximum speed than the 20 miles an hour being attained. But this does not alter the fact that in some cases high speed motors are selected they will be of ample size to correspond formed with slower speed motors at much less expense for power and repairs. When these principles are more generally understood there will not be such a cry as there has been for several years past for high speed motors, and when high speed motors are selected they will be of ample size to correspond with the increased horse power taken by the faster speed.

Connecticut Trolley Notes.

The People's Tramway Co., chartered in 1895, has been organized at Danielson, Conn., by the election of the following officers: President, F. A. Jacobs, Danielson; Secretary, R. L. Warner, Boston; Treasurer, V. W. Rossiter, New York; Directors, F. A. Jacobs, O. W. Bowen, Danielson; A. B. Sprague, Plainville; W. P. Kelley, Dayville; R. L. Warner, Boston; V. W. Rossiter, New York.

Application has been made to the town of Plainville, Conn., by the management of the suburban trolley line, now extending from Hartford to Unionville, for an extension to Plainville, a distance of four miles. The town is now reached by trolley from New Britain. The proposed layout of the extension connects Unionville with New Britain, forming a loop that will afford residents of Hartford facilities for pleasure rides to New Britain and Plainville, then to Farmington and back to Hartford by the way of West Hartford.

Vol. XXV. NEW YORK, JUNE 2, 1898. No. 526.

The Paris Exposition of 1900.

IN view of the reported ill will toward this country manifested recently in France, it is not surprising that there should be a strong feeling here on the subject, and that it should imperil the proposed appropriation for the Paris Exposition of 1900. It would be a great pity if such a sentiment prevailed. France may not apparently be living up to her great traditions of liberty just now. Her notions of internal justice may outrage American ideas of the proper administration of law; and as to external policy, we may marvel at seeing the "grand nation" satisfied to serve as a mere Cossack outpost. As for our quarrel with Spain, if ever there was a war begun on sentimental impulses that might appeal to a generous people like the French, it is the one we are waging for the tortured Island of Cuba; but they do not yet see it with our eyes. Still all this is no reason why we should be as narrow in our actions as the lighter, less responsible element in France appears to be. We are rejoicing deeply at this moment in our new ties of friendship with England, and we do not allow the foolish talk of some snarling irresponsible chatterers to disturb it. In the same manner, we should try to convince our French friends that we wish them well and that we do not take the sneers of boulevardiers or threats of stockbrokers as representative of the true feelings of enlightened France.

He who would have friends must show himself friendly, and now is a time for this country to make itself friends among the nations of the earth in every honorable way. If we can afford to spend $1,000,000 per day in the cause of freedom, we can well afford to spend $1,000,000 in two years in such a cause of intellectual and industrial advancement as the Paris Exposition represents. Yet the proposed appropriation was only $750,000 and there is now talk of cutting it down to $500,000. Such parsimony is wrong. At the present moment we are anxious to push export trade all we can, and Paris in 1900 will be a centre to which buyers will flock from all parts of the world. To them not less than to Frenchmen our appeals and arguments in the shape of our products will be addressed, and the appropriation is as much for them and our salesmen abroad as for Paris.

To put the matter in vulgar parlance, do not let us "cut off our nose to spite our face." At this crisis of national development, we must go before the world not simply with the record of victory over a decrepit power by sheer force and weight of arms, but as seeking those other victories of peace in which alone the permanent welfare of our people must ever rest.

The Development of the Central Station.

THERE are few men who have stood closer to Mr. Edison in the practical development of his lighting work than Mr. Samuel Insull. No one has had a better opportunity of watching the growth of the electrical industry and of learning the lessons which the changes of that growth produced. Hence though entering upon central station management somewhat late in his career, that gentleman is for that very reason peculiarly fitted to pronounce upon the problems presented in central station development from the standpoint particularly of the financier. It is a matter for congratulation, therefore, that Mr. Insull has broken a long silence and given his opinions on some points of vital importance in central station management as embodied in the address delivered before the students of Purdue University. Passing over the purely historical part of Mr. Insull's address, it is evident that he is more firmly than ever convinced of the superiority of the low tension system of distribution as distinguished from the house-to-house converter system. In this contention he is well supported by general experience, and though he does not decry the alternating system, he emphasized the fact, recognized some time ago, that the block converter must supplant the house converter.

Mr. Insull goes into considerable detail in connection with his own station in Chicago, claiming for it the most economical production of current of any such or similar sized stations in the country. In this he will probably not be disputed, situated as he is so fortunately to secure cheap fuel, having at his right hand an excellent corps of engineers and at his left a board of directors who are willing to spend money with a view to the future as well as the present.

But of all the points dwelt on by Mr. Insull, none is of greater moment than his discussion of the cost of product as related to the interest on investment. As Mr. Insull shows, it is quite possible that the station manager may spend so much capital as to eat up many times over in interest charge the saving that he makes in direct operating expenses. Operating cost and interest charge should therefore never be separated. This central station maxim is particularly to be kept in mind in connection with the use of storage batteries. It took Mr. Insull a long time to make up his mind to install the storage battery about going into operation in his Chicago station, but for that very reason he may be considered to be all the firmer in his belief as to the value of that type of station auxiliary. Knowing as we do, that Mr. Insull has given this subject deep thought, it is interesting to learn the results of his study of it. These may be said to be embodied in his statement that it would appear to be economical to use storage batteries in connection with central station systems, the peak of whose load does not

exceed from two to two and one-half hours. As it is safe to say that the vast majority of central station load peaks come within these limits, Mr. Insull's dictum is equivalent to the statement that as a general thing the storage battery will prove a factor of economy in central station work. If Mr. Insull had embodied nothing else in his paper, that one statement in itself would have been a sufficient raison d'être for his address. There are other financial and economic truths scattered throughout this valuable contribution to central station literature which we recommend to the earnest study of all who are interested in making central stations profitable investments.

Some Lessons Taught by the Electrical Exhibition.

THE second electrical and kindred industries exhibition, held in Madison Square Garden, New York, during the month of May, under the auspices of the New York Electrical Society, will in a few days draw to a happy close and leave behind in the minds of thousands memories of a work well done. That the exhibition was a success, no one who has had the good fortune to visit it or has read the accounts of it in the electrical press, will deny, and this in spite of the war and a rainy month of May the like of which cannot be found in the official records. The influence exerted by the exhibition and the lessons which it has taught are too manifold to be enumerated here, but we may point out the far reaching effects of it from the commercial, educational and social standpoints. Taking up first of all the commercial influence of the exhibition, we must emphasize once again the absolute necessity of united effort, good feeling and fair and open competition in order to build up and advance an industry. The fact that firms represented at an exhibition send thereto their best and latest products and see those of their competitors is an inspiration for better effort as well as a valuable bit of information which a wide awake and progressive concern will employ to good advantage. Aside, however, from this tendency to educate manufacturers by placing them in a competitive sphere, the benefits to be derived from exhibiting products are more direct and remunerative in the way of sales made on the spot or later on to persons who have had an opportunity to inspect the apparatus of the various exhibitors. This brings us to the second and equally important function which an electrical exhibition has to perform, namely the educational one. Not only to educate one another, broadly, as an offset to the tendency towards specialization, but to educate the man with theory minus practice, the student and the general public. This is indeed a heavy task, and some may think a thankless one, but the crowds who have daily and nightly visited the exhibition and have expressed high appreciation of the many admirable features which had been arranged, hardly warrant such a belief. Each machine or device, each application shown within and without the Garden has its story to tell, its lesson to impart. And while all these productions were an education by themselves, there were arranged a number of features most of which were strictly educational, while some have already attained commercial importance. No one who has seen the beautiful and inspiring Moore Chapel will ever forget the impression which this novel departure of interior illumination made on him. Add to these numerous features the wax tableaux and the series of popular lectures on electricity by prominent men, and no one will question the phenomenal educational influence exerted by the exhibition.

And now a few words about its social influence on the entire electrical profession. It has cemented many ties of friendship between those engaged in electrical pursuits, which cannot help but bring about beneficial results. As one speaker so fitly said at the dinner of the New York Electrical Society: "We must broaden in our endeavors and carefully guard the interests which are entrusted to us. We must not undervalue ourselves, for in proportion to the value which we place on ourselves, will the outside public regard our worth."

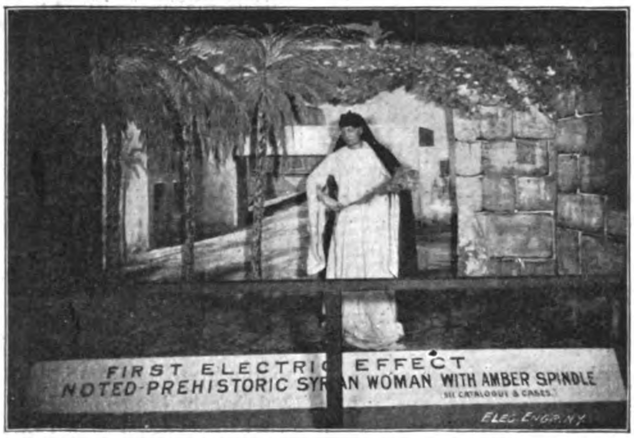
The New York Electrical Society.

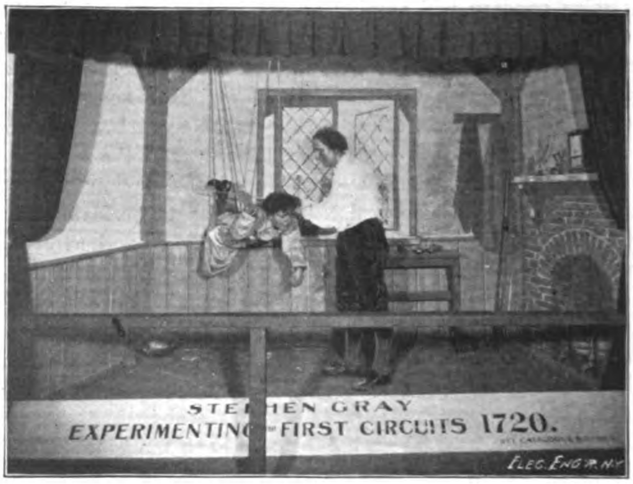
THE annual dinner of the New York Electrical Society served to bring out a representative body of men and demonstrated that both in years and in influence this society stands well in the lead of local electrical bodies in this country. Its work in connection with the present Electrical Exhibition has resulted in a large increase in membership and in increasing its scope of usefulness. The gathering was presided over by the newly elected president, Mr. Gano S. Dunn, and was addressed by a number of speakers who dwelt earnestly and effectively upon various topics of electrical interest. Among them was one which has of late cropped up on several occasions and on which it is well to have some light thrown. Replying to the toast "The Technical Colleges," one of the speakers remarked that the work of our institutions of learning had already left its impress on the art and industry, short as the time had been in which those influences had been at work. But encouraging as the past had been for the electrical engineering graduate there was beginning to be heard the cry that the colleges were turning out too many electrical engineers. Based on an investigation he had made the speaker stated that there was no good foundation for such an apprehension. He pointed out the fact that a great many young men were pushing into the electrical courses of our colleges who ought to have studied law, or divinity, or become professional baseball players, or gone directly into mercantile life. For such there could never be any hope. These men necessarily become itinerants, and the profession could well get along without them. But was it conceivable that our great and enterprising country was incapable of absorbing annually a few hundred trained men in an industry whose expansion has seen no let-up even in the dullest times, and whose ultimate place in the world's economy was written so large that he who runs might read? The speaker insisted that we could not have too many trained men in the electrical field; we were indeed to-day still suffering from the lack of such ten years ago and would continue to suffer for some time to come. It was not necessary that everyone of these electrical engineering graduates should make it his object in life to become the technical head of a factory designing electrical apparatus of all kinds, from a push-button to an induction motor. A couple of dozen such men, it was believed, were sufficient to supply the needs of the whole country. But there were hundreds and thousands of situations in our central stations, large isolated plants, in our engineering establishments, and in our long distance transmission plants where electrical intelligence and training were now recognized as a sine qua non. These were the places which should be sought for, and our colleges are the honored cradles of the new force of men whose value is but now beginning to be felt. The day of the so-called practical man in electrical engineering was fast disappearing. The speaker urged that the colleges go on with their good work and believed that when the wail "overcrowded" was heard it was the voice of an unfortunate who had missed his calling. The lesson which the speaker evidently desired to bring home to his auditors was that electrical engineering will for a long time to come occupy a promising field for young engineers, but that in this, as well as in every other profession, only those can hope to succeed who have at least a fair amount of natural aptitude for the work and a proper training therein.

The Historical Wax Tableaux at the Electrical Exhibition.

THIS is an educational age and the effort to impart information takes many forms. For the great mass of the public, it is certain that the instruction must be conveyed in a very attractive manner if it is to be useful; and if this instruction can be given entirely the character of amusement it seems to achieve its fullest success. At the Electrical Exhibition this idea has been worked out in various ways, but perhaps in no instance is the result happier than it is in the Historical Wax Tableaux, placed in eight large alcoves around the Concert Hall. The location of these groups is in many respects ideal, the niches are of just the right size, there is space in between them for cases containing literature that illustrates or explains, and as in a picture gallery people can also sit down quietly and study the subject should they wish to do so. The popularity of the Wax Tableaux has been emphatic since the very start. In the afternoon, when little of the machinery is running and when few of the lights in the main hall are turned on, the Tableaux constitute a considerable item in the list of attractions, especially for the throngs of younger folk. In the evening, the groups and cases are densely surrounded, and the real genuine interest taken is shown by the manner in which people read every line, discuss the subject, and often give intelligent explanations to each other, showing how thoroughly well they have grapsed the underlying idea of the evolution that is set forth. It is said that such a systematic attempt to teach history in a science or art has not been made before, and the success may well lead to other attempts in similar directions.

The groups were selected, as to subject, etc., by Dr. Park Benjamin, Prof. F. B. Crocker and Mr. T. C. Martin. They were carried out by the Eden Musee Company, of New York, who, as might have been expected, have done a clever piece of work very neatly. The groups are enclosed by dark drapery and railed in front, from case to case of books, so as to present a continuous line. Banks of colored lamps are sprung into the tops of the alcoves on molding strips, and other lamps are disposed to secure the best lighting effects, which were carefully elaborated by Mr. Max Osterberg and Mr. Lardner, of J. G. White Co. The Concert Hall is decorated in white tints, so that the groups are thrown up in high, artistic relief, producing a most beautiful effect.



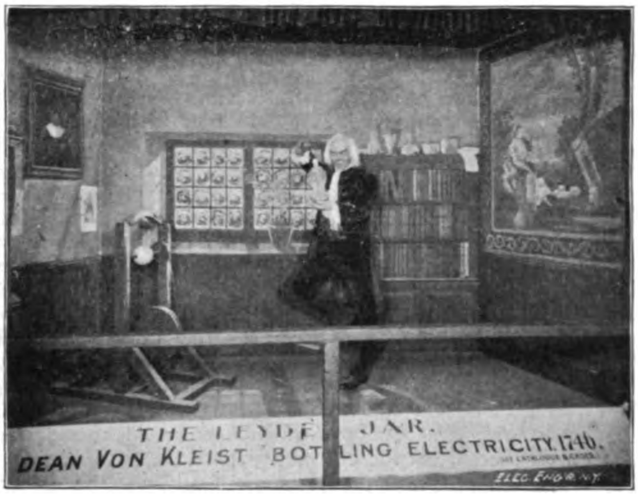


As to the Tableaux themselves and their themes, we cannot do better than reproduce the brief "keys" to them furnished by the Official Catalogue, as follows:

1. The First Recognition of an Electric Effect.—A Syrian woman centuries before our era wonderingly perceives light objects fly to her amber spindle. Prehistoric.—The first discovery of an electrical effect is commonly ascribed to Thales of Miletus, who lived about 600 B. C. But the Syrian women span thread and made cloth long before Thales lived, and for ages they called their amber spindle the "Harpaga" or "Clutcher." This because when it swiftly revolved as it hung on its thread it rubbed against the wearer's dress, and thus becoming electrified it attracted or clutched to itself loose leaves, chaff, and other light objects.

2. The Mariner's Compass. (11th and 12th Century.)—The invention of the Mariner's Compass is sometimes erroneously

ascribed to the ancient Chinese and sometimes to the Italians of the 14th century. It was probably first used at sea by the "wonder-working Finns," in the 11th century, and its invention goes back to the prehistoric dwellers in the valley of the Oxus, from whom knowledge of it spread northward and eastward. The first compass was a needle of iron rubbed with the loadstone and placed in a little bowl which floated in a vessel of water. It served merely to indicate the position of the Pole Star when the sky was overcast. It did not indicate the ship's course as it does now. The old Norse sailors guarded both loadstone and needle with great jealousy, knowing that the safety of the vessel depended on the accuracy of the instrument. But pirates, shipped aboard sometimes as honest seamen and waiting their opportunity, falsified the needle by rubbing it wrongly so as to lead the vessel to wreck and plunder. For this the savage punishment represented was imposed by the Laws of Westby, a sea code of great antiquity. The culprit had a knife thrust through his hand into the mast, and there he was compelled to remain without food or drink until he tore himself free in such way as to leave at least half of his hand behind.



3. The Earth a Great Magnet.—William Gilbert Explaining the Terrella to Queen Elizabeth, A. D. 1600.—Dr. William Gilbert, the father of electricity, was born in 1504, and died in 1603. He was the first to discover the fundamental facts of electricity by purely inductive reasoning—in advance of Bacon, and he gave the science its name. He was Court Physician to Queen Elizabeth, of England. He made many of his magnetic experiments on a globular magnet representing the earth in miniature and hence called a Terrella. This he is represented as explaining to the Queen.

4. The First Conductors or Circuits.—Stephen Gray Experimenting on the Conduction of Electricity, A. D. 1720.—Stephen Gray was a Charterhouse pensioner in London, England. He discovered that the electric current would traverse cord for long distances and pass over a great variety of bodies. He also discovered that it could be kept on those cords provided they were "insulated" by suitable materials, such as silk. His experiments were made with the most homely materials—bricks, stones, coffeepots, canes, fishing rods, etc.—and some of the most striking of them, showing the passing of the current through the human body, were made as here represented on the lads of the Blue Coat School and Charterhouse School, who took much delight in helping him.

5. The Leyden Jar.—The Bottling of Electricity and the Terrible Shock of Dean Von Kleist, A. D. 1746.—Up to the middle of the last century no one believed that electricity could be confined, and that it would escape as fast as generated. Dean Von Kleist, Canon of the Cathedral in Cumin, in Pomerania, Germany, directed the discharge of his electric machine upon a nail which entered a glass bottle of water, hoping thus to entangle the electricity somehow in the water. The experiment seemed to be a failure; so, holding the bottle in one hand, he essayed to draw out the nail with the other. To his intense astonishment, and although the bottle was entirely disconnected from the machine, he received a violent shock. This resulted in the discovery of the Leyden jar, or electrical condenser. When Von Kleist touched the nail, he completed the first artificially made electrical circuit.

6. Identity of Lightning and Electricity.—Franklin Drawing Down the Lightning from the Skies, A. D. 1752.—The great question was whether the lightning in the heavens was the same as the spark made by the electric machine. The French philosophers put up iron rods ninety feet in the air or so in height and during thunder storms drew sparks from them. Franklin held that this did not prove anything, because the iron rods did not go to the clouds. Hence he made a kite out of a silk handkerchief, with two cross sticks and a bit of projecting steel wire, and sent it up from the Commons, near Philadelphia, during a violent thunder storm. He insulated the hemp

kite string from his body by a piece of black silk ribbon, and as a terminal fastened a metal key to the string. When the storm was at its height and the kite buried in the clouds, he touched his knuckle to the key and obtained electric sparks, with which he afterwards charged Leyden jars in the ordinary way. The act was one of astonishing audacity and bravery, for all existing knowledge went to show that it would certainly result in his death.

7. The Beginnings of the Modern Primary Battery or Voltaic Cell.—Galvani's Famous Frog Experiment. (Date Uncertain. Galvani's Essay appeared in 1791.)—A classic, accidental experiment of no particular importance in itself but famous all over the world and commonly adduced as the beginning of the production of electricity in the Voltaic cell. In fact, it marked the beginning of the long controversy between Galvani and Volta, and the outcome of that was the invention of the cell by Volta. The story of it is here represented. Galvani was making some experiments before friends or students in his laboratory. Mrs. Galvani was skinning frogs' legs for soup. One of the company accidentally touched the legs with a knife, when they violently contracted. Mrs. Galvani noticed that this happened coincidentally with the production of a spark from the electrical machine. Galvani tested the matter and proved such to be the case, and in a short time the world had the galvanic or voltaic cell which converts chemical action into electricity by means of two unlike metals moistened or dipped into a liquid.

8. The Beginnings of Modern Dynamo-Electric Machinery.—Faraday's Famous Experiments, A. D. 1831.—Michael Faraday, one of the greatest philosophers the world has ever seen,—a self-made genius—did much of his work at the Royal Institution, London, England, and in his lecture hall made many famous and immortal demonstrations. This is one of them. He is shown standing at his lecture table, which is still there. It having been proved that by means of the electric current, a body of iron could be converted into a magnet, Faraday wound a coil of wire around a piece of soft iron. The wire being insulated by calico and tied by string, on moving this bar and coil before a magnet, he was able to produce a spark at the gap in the coil of wire. From this little experiment, of producing electricity by magnets, sprang all the vast modern development in dynamo electric machinery, and all the art thereon depending, in light, heat, traction, power, etc.

It will be seen that the series closes at a natural point and just where the industrial part of the Exhibition takes up the story. The groups have evidently been studied out with great care, not with the idea that they might be exactly correct in every microscopic detail of archæological data, but in the broad, helpful sense and with the object of assisting study and memory in a graphic way. The Gilbert group, for example, assumes that Queen Elizabeth in one of her progresses through Essex has naturally called on her own court physician at his quaint house in Chelmsford to see with womanly curiosity what he is really driving at, and the interior is roughly drawn after one of the pictures of a laboratory in his own "De Magnete." In the Faraday Tableaux, several portraits were studied, the Royal Institution background is drawn from a photograph of the lecture hall, and on the table are instruments of the very time loaned by Dr. R. Ogden Doremus. In the adjoining case is one of Faraday's own little experimental magnets loaned by Mr. C. O. Baker, Jr., the president of the Exhibition. Whatever the inevitable shortcomings of such an effort to create living pictures out of the past, there can be no question as to the many meritorious features of this attempt and certainly none as to its immense popularity with visitors to the Exhibition, technical and lay alike. We shall not be surprised to see the example thus set followed and imitated.

MANAGER McDONALD, of the local telephone exchange, has taken the position of general manager of the new concern, the Augusta, Ga., Electric and Construction Co., which will do a general electrical business at 212 McIntosh street. He will have associated with him Mr. B. R. Mitchell as superintendent of construction.

NO ELECTRICITY IN TURKEY.—The Sultan has, it is alleged, now prohibited the use of electricity in Turkey for any purpose, and patents for electrical inventions are consequently refused.

Running Notes on the Electrical Exhibition.

Edison at the Show.

Despite the phenomenal and unparalleled wet weather—attributed popularly to the close relationships existing between this country and England—the attendance during the past week has been very large, and it may, with appropriate use of the term, be said to have rained celebrities. We give here a happy little snapshot of Mr. Edison on one of his visits, caught in the Edison temple and just about to have some "electric shortcake" with two of the Edison Co.'s officials—Messrs. Arthur Williams and J. W. Lieb, Jr.; and it may be noted that many of the distinguished folk "round up" in this way to enjoy the Company's hospitality before going away—a cup of tea or coffee, a hot biscuit, strawberry shortcake or whatever the electric kitchen may have been busy on.

The telephone had its share in the successes of the week, particularly in its long distance work. Three or four of the comic operas playing in the city are brought to the Theatrophone board, but not satisfied with that the New York Telephone Co. introduced on Monday night a concert by the famous Lauder Orchestra then playing in the Palm Garden at Milwaukee, about 1,100 miles away. In spite of the drenching rain, the music came through very satisfactorily to the delight of a large number of auditors. On Wednesday evening Sousa's march, "Unchain the Dogs of War" from "The Bride Elect," was switched through the Theatrophone to the White House in Washington, where Mrs. McKinley and a party of friends enjoyed it immensely. Mr. F. W. Hawley engineered the thing, and Messrs. Webb, Brewster and Dowd carried out the arrangements perfectly. The performance attracted considerable attention on the part of the city newspapers.

An ingenious innovation during the week in the Moore Chapel was the introduction of an Edison phonograph to take the place of a parson. There is already a fine church organ which is played continuously by a good organist, but it was felt that this hardly carried out the ecclesiastical idea to the full. Accordingly Messrs. William Edison and E. M. Smiles loaded a phonograph cylinder with the Lord's Prayer, the Twenty-third Psalm and the Beatitudes. The phonograph has been mounted on the chair at the altar with its brass funnel sticking out over the lectern, and the throngs of people as they walk through are greeted with the familiar sacred passages. The effect on the auditors is remarkable, and the comments suggest that many new possibilities are opened up for poor churches and outlying parishes, especially as many phonograph cylinders now carry hymn words and tunes, and as mechanical organs can obtain an inexhaustible supply of roll music of a religious character. A whole church service run by machinery impends in the near future.

The Exhibition would normally close on Tuesday of this week, but as an offset to the bad weather it has been decided to round out the week by continuing open for the other four days. To this plan practically all the exhibitors have given their cheerful assent.

Exhibit of the Walker Company at Madison Square Garden.

CONSPICUOUSLY located on the main floor and occupying a space of 800 square feet is the very interesting and instructive exhibit of the Walker Company, of Cleveland, Ohio. No attempt has been made to decorate the space elaborately as that might hide some portions of the heavy machinery from view. Open framework surrounds the booth which has a number of entrances open at all times to the interested visitors. Within the space this enterprising company have placed representative apparatus of each department, the most prominent ones being the railway apparatus. There is shown a heavy McGuire truck for double truck cars, equipped with two Walker 20-L motors for elevated or heavy suburban traffic. They are

of the type built for the Metropolitan "L" Road of Chicago. The motors have a capacity of 150 horse power each, and a car equipped with two of these trucks has therefore a capacity of 600 horse power. Regardless of this heavy output, the equipment is no larger in height or wheel base than ordinary standard trucks. The wheels of this truck are raised from the floor and the motors are shown in operation, being controlled by a type S solenoidal blowout controller, the cover of which has been removed. Naturally this has attracted a great deal of attention, as have also the parts of the controller which are exhibited on a platform. There is also shown a standard street railway equipment complete, furnished with No. 4 A. S. motors and a Peckham centre-bearing swing-bolster, maximum traction truck equipped with a 25 horse power motor. The Walker underground conduit system is clearly and effectively shown in the full size conduit section and car, which is in operation on the main floor. The new design Walker pivotal trolley base fitted with pole and Grover head is also shown, and the street railway switchboard with generator and feeder panels has attracted a great deal of attention. These panels are fitted with Weston volt and ammeters, I. T. E. circuit breakers, triple grid field rheostats, Garton lightning arresters, etc.

Besides this railway apparatus, there is shown a 50 kilowatt Walker alternator. The peculiar feature of this machine is that the armature is the stationary and outer member, while the fields revolve and are excited by a single field winding concentric with the shaft. A composite field winding is employed, the series coils being supplied with current by a rectifier. In the generating section in the basement the company have a 50 kilowatt lighting generator direct connected to an Armington & Sims engine, and a 25 kilowatt lighting generator direct connected to a Nash gas engine. The former unit supplies lights to the building and the current is distributed from a handsome isolated switchboard installed by the Walker Company.

They also show their well known enclosed arc lamps for either multiple or series circuits, the mechanism of which consists of a chain fastened to the upper carbon holder, running over a sprocket wheel and being partially counterweighted. A magnetically actuated clutch operates on a pulley coupled to the sprocket wheel.

But the instrument which has attracted the greatest interest is the new integrating direct current ammeter shown in actual operation. It consists of a flat copper disc, upon which are spread out three coils of wire, connected to a long, slim three-part commutator through which the current to be measured is introduced. Permanent magnets react upon these coils and generating a Foucault current in the disc brake, a torque is introduced which is proportional to the current to be measured. The instrument is extremely simple and compact and is claimed to be very accurate. There are very few moving parts, and these, as well as the dials, are all in plain sight of the consumer or attendant.

Besides showing the above numerous products, the company expect to exhibit before the close of the exhibition a number of 20-L motors, such as were recently installed in Chicago and which have already been shipped from the factory at Cleveland. A vast amount of interesting and artistic literature bearing on the manufacture of the Walker apparatus is distributed, and a stand has been erected in one corner of the booth on which are mounted photographs of prominent Walker installations. The company is ably represented by Mr. J. S. Anthony and a corps of assistants.

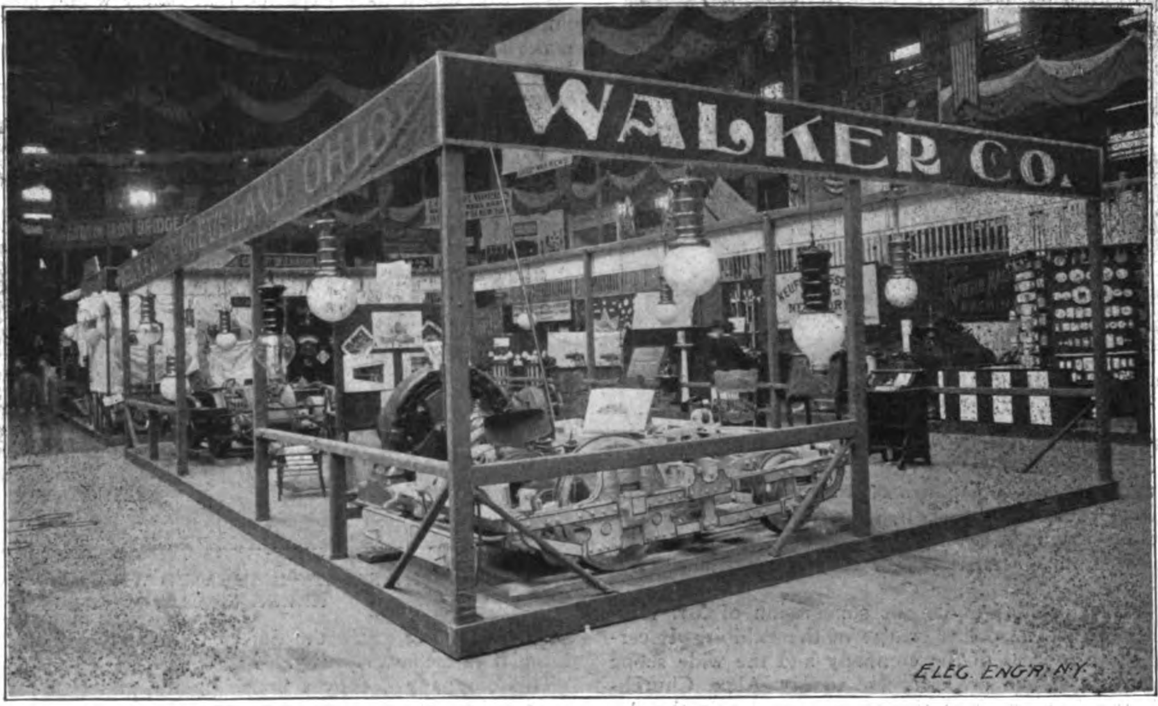


EXHIBIT OF THE WALKER CO., OF CLEVELAND, MAIN FLOOR.

Exhibit of the Excelsior Electric Company, Churchward Apparatus.

ONE of the largest and most striking exhibits on the main floor of the Garden is that of the Excelsior Electric Company, manufacturers of the Churchward apparatus. The exhibit is particularly striking on account of the great variety and originality of the apparatus shown, most of which has never been exhibited before. Among the novelties should be mentioned a single-phase self-starting alternating current motor driving a Blackman fan, showing its ability to start and bring its full load up to speed. This machine is fitted with the company's automatic starting device whereby the current is closed at the main switch. The machine starts and comes up to synchronous speed automatically. This type of machine has been designed especially for elevators, pumps, or ventilator service, where the motor has to be started automatically. Another specialty is the single-phase self-starting alternating current motor fitted with the latest type of starting switch operated by hand. It is fitted with open circuit and overload circuit breaker. There is also a single-phase self-starting rotary transformer operating an "Otis elevator." This machine demonstrates the utility of single-phase rotaries.

Other special features are: One 30 k. w. high frequency rotary 16,000 alt., either single, two or three-phase, demonstrating the practicability of high frequency rotaries; a 1½ h. p. slow speed ironclad enclosed type motor, direct connected to a standard air-brake compressor for street car work. There are 100 of these now in operation. There is also exhibited the latest type of

direct connected generator, showing brush holder supported by frame. The capacity of the machine is 75 k. w. at 275 r. p. m.; also a 2 h. p. multipolar motor and 22.5 k. w. compound generator, belted type; 1 k. w. and 15 k. w. belted type armature, and a 75 k. w. direct connected type armature; various sizes of the latest patented carbon brush holders; an experimental rotary transformer for lecture, educational and experimental purposes,

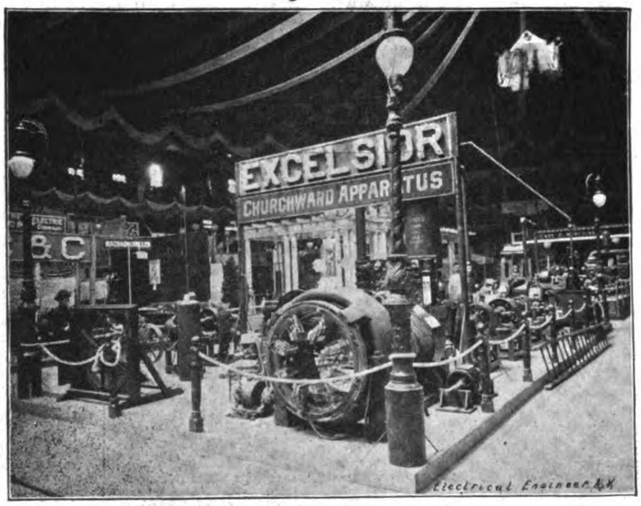

EXHIBIT OF EXCELSIOR AND CHURCHWARD APPARATUS, MAIN FLOOR.

which starts on single-phase and converts to two or three-phase, monocyclic and direct current, or vice versa; also direct current 2 to 3-wire rotary transformer; slow speed 10 h. p. 150 r. p. m. motor for direct connection to tools, etc.; latest type of Excelsior arc machine having a capacity of 100 lamps of 2,000 c. p.; latest type of arc lamps, semi-enclosed, as well as arc motors in operation.

The exhibit was installed under the supervision of Mr. Herman Hochhausen, who also has charge of the exhibit. It certainly shows the resources of the company and the wide scope of their apparatus. Much credit is due to Mr. Alex. Churchward, the electrical engineer of the company, who is the designer and inventor of this admirable lot of electrical machinery.

The Exhibit of H. B. Kirkland.

IN this interesting exhibit, on the main floor, are displayed the goods of several well known concerns, which Mr. Kirkland represents. To the right of the entrance to the booth stands an immense pyramid of The American Circular Loom

COMBINATION EXHIBIT MADE BY H. B. KIRKLAND.

Co.'s flexible conduit, showing to advantage the various sizes in which it is manufactured. At the rear of the booth the Cutter Electric & Mfg. Co.'s circuit breakers and switches are shown mounted as for switchboard use. Like the conduit mentioned above, these goods are too familiar to everybody to need any description. Standing at the left of the Cutter display is a handsome oak case containing a full line of the excellent specialties made by the Solar Carbon Mfg. Co., of Pittsburg. This includes battery, carbons, telephone carbons, carbon brushes, etc. The Hope Electric Appliance Co., of Providence, R. I., show their arc cut-outs and quick break switches in various sizes and types. Taken collectively the exhibit is a very creditable one.

Mr. Frank Loughlin, treasurer of the Solar Carbon Co., was a visitor to the Show last week.

Safety Insulated Wire and Cable Co.

THOSE who remember the exhibit made by this company in 1896 might have expected that Safety would make a striking display, and, in truth, they have not been disappointed. To make an insulated wire exhibit attractive to the layman, is no

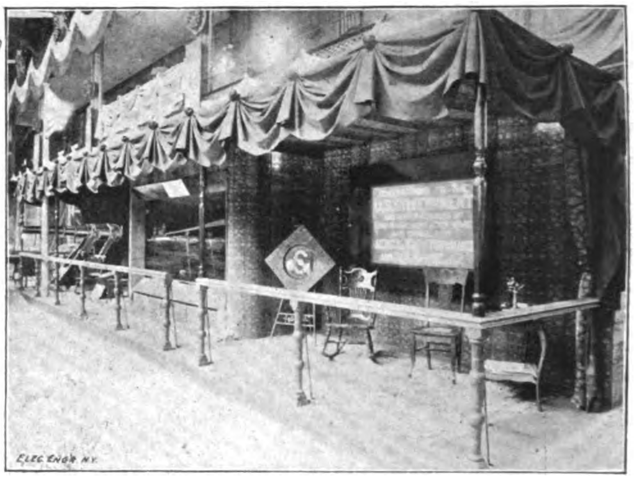

EXHIBIT OF THE SAFETY INSULATED WIRE AND CABLE CO., ARENA CIRCLE.

easy matter, but again the Safety Company have succeeded in doing it in a masterly way.

This company occupy a booth on the gallery floor which is divided into three apartments. In the first is a model of a 4-inch disappearing gun which attracts a great deal of attention. There is also a section of a submarine telephone cable of the

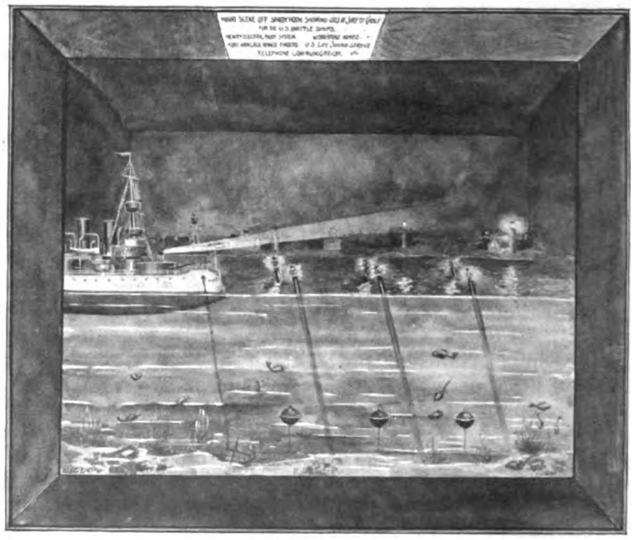

EXHIBIT OF SAFETY INSULATED WIRE AND CABLE CO., SHOWING METHOD OF WIRING SUBMARINE MINES.

future, labeled, "The largest section of submarine cable ever manufactured, and designed for telephone communication between New York and London." This specimen is about 16 inches in diameter, with a core of 66 copper rods about half an inch in diameter, not insulated from each other, however, but having a band of rubber insulation outside, and outside of this strands of large steel bars for strength, then a bed of jute, with outside armor. It has a sectional area of 32,745,913 circular mils, and

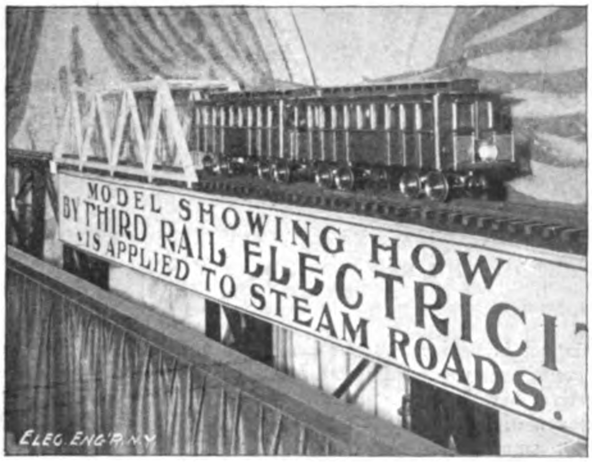
it gives a vivid picture of the difficulties which have to be encountered in transatlantic telephony.

The middle section of the booth presents a most charming and realistic picture, designed to represent a night scene off Sandy Hook, New York. It consists of a tank 12 feet long, 30 inches deep, and 6 feet wide, having a glass front, and filled with water. Through this is shown a shelving bank of sand, with seaweed growing on the bottom and dozens of gold fishes moving hither and thither among miniature submarine mines and electric buoys. Floating on the water is also a model of the battleship "Oregon," with a miniature searchlight mounted on the mast.

The third section of the booth contains specimens of various types of insulating wire manufactured by the company, of which it supplies large quantities to the Government for submarine work. Specimens of all varieties of electric light wires and conductors for high tension transmission are also shown.

Third Rail Model at the Electrical Exhibition.

IN many noteworthy respects the present Exhibition differs from that of 1896, but perhaps in none more than in its inclusion of railway apparatus. It goes without saying that the exhibition is rendered far more complete, for while actual cars and machinery are shown in operation, the public is also able, from a model, to see how the third rail is operated. In the Assembly Rooms, immediately adjoining the Moore Chapel, and in fact with delicious but unavoidable incongruity running right along the outer wall of that famous sanctuary, is a very neat and handsome model intended to exhibit the operation of the third rail system of electric traction as in use by the New York, New Haven & Hartford R. R. Co., on its branch line between Berlin, New Britain and Hartford. The power current passes along the centre rail to the sliding contact shoes



THIRD RAIL MODEL AT THE ELECTRICAL EXHIBITION.

which are seen under the car trucks. A flexible cable from each shoe conveys the current up to the motor and lights. The current returns from the cars by way of the trucks, wheels and outer rails. The change of direction of movement of the model is accomplished by an electro-magnetic reversing switch, which may be seen in the middle of the combination car. This switch performs three functions: reversal of the motor, interchanging the headlight and the rear light, and selecting the signals.

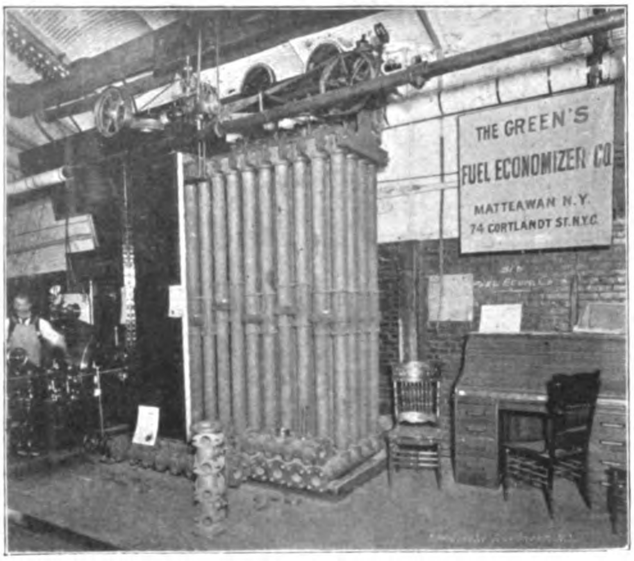
The discontinuance of the third rail at the crossing causes no interruption of current, as the first contact shoe makes contact on the forward rail before the third shoe has left the rear section of rail.

There are two cars, one of which carries the motor and the other is for passengers only. The motor car, as very often in electric railway practice, is a combination car, smoker, etc.

The track is 5-inch gauge, and nearly sixty feet in length. The model as seen in operation, has been furnished by Mr. H. V. Parsell, Jr., E. E. Some details of apparatus as used in the actual working of the road, are also shown through the courtesy of Col. N. H. Heft, in charge of the electrical department of the N. Y., N. H. & H. (Consolidated) R. R., New Haven, Conn. The road is shown with a regular bridge crossing. The whole thing is fenced in by a hand rail and is in charge of an attendant who explains the features of operation to the large and inquiring crowds.

Exhibit of the Fuel Economizer Co.

THE Fuel Economizer Co., of Matteawan, N. Y., sole makers of Green's fuel economizer in this country, show one of their standard economizers of small size containing forty-eight pipes made up in twelve sections, four pipes wide; also a section of their sectional covering, which takes the place of the ordinary brick wall. This covering is made up of sheet steel with two inches of non-conducting material in the centre. Should any accident happen to the headers or pipes, any of these sections can be unbolted in a few minutes and an examination made, and if necessary the header and pipes can be withdrawn sideways. They also show one of their patent headers with valves in position. This header enables the economizer to be worked either with mechanical circulation or without. The valves in headers are connected together by levers. When the headers and pipes require blowing out for cleaning purposes,



THE FUEL ECONOMIZER CO.'S OPERATIVE EXHIBIT, BASEMENT.

the levers are moved, instantly opening the whole of the valves and leaving a clear passageway in headers for the water to pass out. This apparatus is very simple and works well in practice. Briefly explained, the Green economizer utilizes the gases that usually go directly from the boiler up the chimney. The economizer is a nest of pipes built in a flue, the gases passing between the pipes. The feed water circulating through and inside the pipes extracts the heat from the gases in their passage between the tubes. Automatic scrapers are used to remove all soot that might collect on the outside of the tubes.

This apparatus has been applied to over 200,000 boilers and is working in all parts of the world. The Fuel Economizer Co. express their willingness at any time to guarantee a saving of 10 per cent. in fuel, where the very highest type of boiler, and where triple or quadruple expansion condensing engines are used. In some cases as high a saving as 30 per cent. is made, but where such high saving is effected, the boilers are either of a crude type or worked much above their rated capacity.

Last week they sold three economizers for 2,500 boiler horse power, where the coal only costs about 12 cents per ton delivered on the boiler house floor. The exhibit, which is located in the generating section, is in charge of Mr. W. Downs, the New York representative.

B. F. Kelley & Son's Berryman Heaters.

MESSRS. B. F. KELLEY & SON, of 91 Liberty street, in this city, are showing their well known fuel saving device in the generating section.

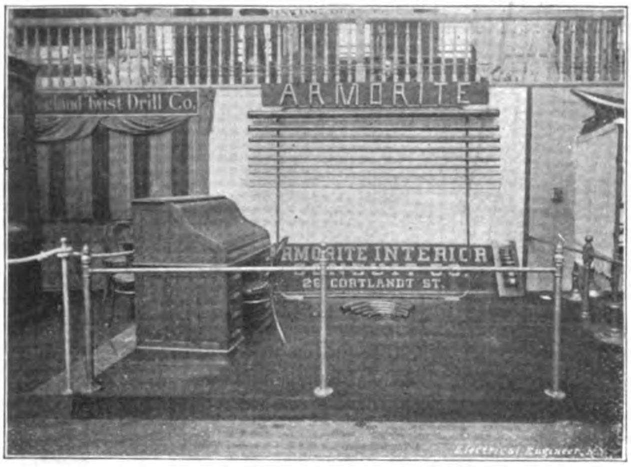
It is the improved Berryman (Kelley's patent) water tube feed water heater and purifier of 300 horse power capacity, supplying hot water for the exhibition steam boilers.

The water when entering the heater is cold, and by the ingenious construction of this apparatus and the aid of exhaust steam it is almost instantly heated to about the boiling point. It is a little giant at heating and purifying water and keeping

steam boilers clean and free from scale. At their exhibit, where the other specialties manufactured by the firm are shown, the great contrast between the "old style" Berryman and the "improved" is attracting the attention of the mechanical engineers. Any information can be obtained from their representative, Mr. information can be obtained from their representative, Mr. George Ernst, at the Garden, or direct from the main office.

Exhibit of the Armorite Interior Conduit Co.

An exhibit which is attracting a great deal of attention on account of the unique display is that of the Armorite Interior Conduit Co., 26 Cortlandt street, New York. The exhibit is located on the main floor to the right of the main

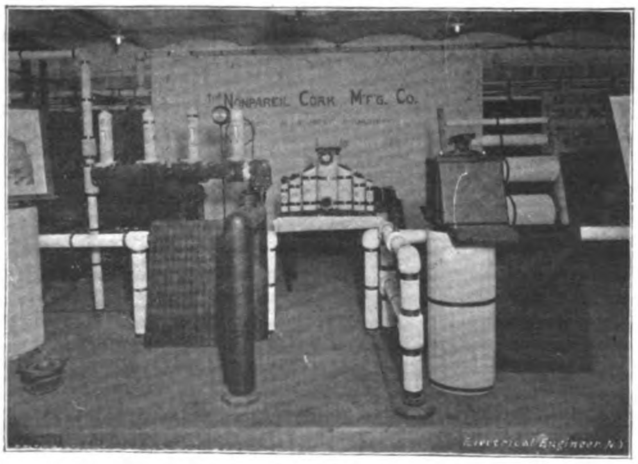


THE ARMORITE INTERIOR CONDUIT CO.'S EXHIBIT.

entrance and on a rack at the back of the booth are arranged a number of samples of Armorite conduit of different sizes and 10 feet long. There are also shown a number of armor-duct enameled tubes and plain and asphalted conduit tubing and fittings.

Exhibit of the Nonpareil Cork Mfg. Co.

One of the exhibits in the generating section, which has attracted a great deal of attention on account of the novelty of the product shown and the great variety of its uses demonstrated, is that of the Nonpareil Cork Mfg. Co., of Bridgeport, Conn. They are showing sectional cork covering for steam and brine pipes, cork sheets for lining the walls of ice houses and refrigerating plants, cork tiles for flooring and insulations for third-rail system. The covering is claimed to be more durable,



THE EXHIBIT OF THE NONPAREIL CORK MFG. CO.

efficient and economical than any other pipe covering, as was shown by a severe test of the several materials in use. It is easy of application and light. The process of manufacture consists, in part, in subjecting the sheets to great heat while under pressure. This, by liquefying the natural gum of the cork, forms the interstices between the granules into small closed air spaces, without destroying the myriads of minute air cells which give cork its wonderful heat non-conducting properties, and without the addition of any foreign cementing substance, produces a solid sheet or block of cork.

As 4 inches of granulated cork are reduced to 1 inch thickness, it is not difficult, even for those whose experience with insulating materials is limited, to appreciate the advantage obtained by using Nonpareil Sheet Cork. The company are prepared to furnish samples of their covering for test to anyone on application, and they have taken numerous large orders at their exhibit, showing that the engineers who have attended the show appreciate the merits of the cork covering.

New York Safety Steam Power Co.'s Exhibit.

Occupying a very prominent and spacious corner in the generating section is the exhibit of the New York Safety Steam Power Co., of 107 Liberty street, New York. They show in operation one of their new type 13 x 12 vertical automatic cut-off heavy duty engines direct connected to a 75 kilowatt Fort Wayne generator. This engine is of the heavy railway type, extra heavy shaft, crank pin, crosshead pin and boxes. It is fitted with the improved Nichols governor. It is simple in construction and has few parts to get out of order. Its

EXHIBIT OF THE NEW YORK SAFETY STEAM POWER CO., BASEMENT.

regulation is perfect, as the governor will regulate within 1½ per cent. from no load to 25 per cent. overload. Their representative, Mr. John T. Simons, reports to have received orders for seven of the company's engines since the exhibition opened, besides smaller engines of this type, a number of which are shown in the space. Being the only vertical steam engine exhibited, it has attracted a great deal of attention and has received many favorable comments.

Le Valley Vitae Carbon Brush Co.'s Display.

An exhibit which has attracted considerable attention is that of the Le Valley Vitae Carbon Brush Co., 39 to 41 Cortlandt street, New York. In a number of glass cases in the front of the booth are shown the various styles and sizes of the company's carbon brushes and commutator compound. The Le Valley Vitae brush differs entirely from all other self-lubricating brushes. There is not a drop of grease or animal oil employed in the treatment; consequently the segment strips or commutator will not clog or gum. The brush lubricates constantly and uniformly as it slowly wears away, preserving at all times an even, bright and polished surface. It never crumbles nor cuts in the least possible manner. In using this brush the commutator is somewhat discolored by the lubricant, but an examination will show that there is no oily or gummy substance on the surface of the commutator; and this discoloration can be easily wiped off with a rag, showing the surface of the commutator much brighter, smoother and cleaner than ever before.

The wear of the commutator with the use of this brush is almost imperceptible, and as this slight wear is uniform and

smooth, it requires no sandpapering or turning down, thus preserving the commutator almost indefinitely.

The company have received many flattering testimonials, one of which states that one of the company's carbon brushes was used on a railway motor which ran the car over 6,000 miles of track and the brush only wore down ¼ inch. In the back of the booth is hung a large carbon brush and all questions are cheerfully answered by Mr. E. J. Prehn.

Exhibit of the Standard Fire Proofing Co.

THE Standard Fire Proofing Co., of 39 Cortlandt street, New York, and Perth Amboy, N. J., who created such a sensation of late with their vitrified and salt glazed underground conduits, have a very neat exhibit on the main floor of the Garden. One of the most remarkable products of the company is a duct 18 inches long with male and female thread. The salt glazed conduits are manufactured from the finest quality of fire clay, mixed and prepared in machines especially constructed for the company's use. They are properly dried, thoroughly and uniformly burnt, heavily glazed inside and out. They are made in any length desired up to six feet in 2, 3, 4 and 6 ducts, perfectly aligned. The outer walls and partitions are 9-16 inch

EXHIBIT OF THE STANDARD FIREPROOFING CO.

thick. The duct or opening is 3¼ inches by 3¼ inches, with rounded corners. The alignment of the conduits is perfect, the ends fit exactly and are provided with openings for the use of iron dowel pins. The partitions add to the solidity and strength and give immense bearing strength. A six-foot-six-duct conduit laid on supports with 5½ feet between bearings will support eight tons. Laid on a smooth bed of concrete there is no limit to bearing strength.

The construction of the multiple of ducts affords an economical means of laying, no high-priced labor being required. The interior is heavily glazed and the round corners of the ducts reduce the friction to a minimum, thereby reducing resistance and saving wear on the cable, also permitting manholes to be placed far apart. There are no sharp points to catch and tear cables.

The cables can be pulled in with little resistance and no wear. Manholes can be placed far apart. They are proof against frost. heat, water or acids. All questions relating to the conduits are cheerfully answered by Mr. M. J. Harrington.

Exhibit of the American Electric and Novelty Co.

IF there is any one exhibit which brings out in a striking manner the use of electricity for decorative and display purposes, it is that of the American Electrical Novelty and Mfg. Co., of New York. In a handsomely decorated booth on the main floor there are shown a large number of potted flowers, illuminated from within and behind by miniature electric lights concealed from view. The power furnished for these lamps is also cleverly concealed.

These plants, used for decorative and advertising purposes, cuits are employed, in which case both wires are lassoed.

There are also shown night lamps, and the well known "Ever Ready" electric light, which is put up in bicycle lamps, electric gas lighters and other useful forms. A striking feature of this exhibit is a figure of Uncle Sam holding under his arm a telescope so well lighted with the "Ever Ready" electric light, that apparently he would have no difficulty in finding with the help of this instrument the lost, strayed or stolen Spanish fleet.

Drop Forgings Exhibited by J. H. Williams & Co.

A VERY tastefully arranged and highly original exhibit is that of J. H. Williams & Co., Brooklyn, N. Y., manufacturers of drop forgings. At the back of the booth is hung a large colored picture showing one of the immense forge rooms of the company. Around the frame of the picture are placed miniature incandescent lamps and the effect is very pleasing. Around the sides of the booth are hung panels, covered with samples of the numerous products of the company, such as eyebolts, engineers' wrenches, special forgings for all kinds of electrical apparatus, made to order, lathe dogs and spanner wrenches. One of the latest pieces of apparatus manufactured

THE EXHIBIT OF J. H. WILLIAMS & CO.

by the company is the Vulcan patent drop-forged steel chain pipe wrench for gripping, turning, or holding pipe, bolts, bars, shafts, etc., from ⅛ to 12 inches in diameter, with either cable or flat link chain. These wrenches combine the merits of all other chain pipe wrenches with special advantages of their own. They are strong and durable, made wholly from wrought steel. The drop-forged jaws are of saw temper; the teeth can be sharpened by filing only. The pressure of the teeth is in a line tangent to the circumference of the pipe; which, combined with the encircling grip of the chain, prevents crushing.

On standards in front of the booth are mounted imitation guns, the gun itself consisting of a field magnet forging and the wheels of drop-forged gear wheel blanks. The exhibit is attracting a great deal of attention, and the many questions asked are always cheerfully answered.

Garvin Machine Co 's Exhibit.

THE exhibit of the Garvin Machine Co., Spring and Varick streets, New York, is very attractive and also neatly arranged for their rather confined space. It has proved especially interesting to the large number of practical men and mechanics of numerous concerns who have visited the exhibition, and it shows a great stride made recently by machine tool builders.

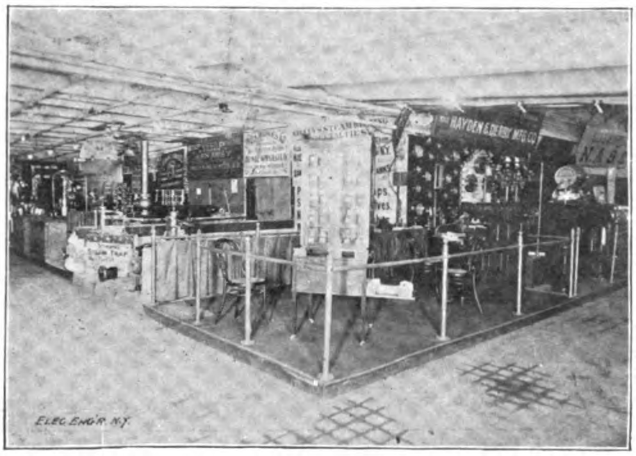
Two machines are shown; an automatic tapping machine and a wire feed screw machine, both used very largely in electrical manufacturing. The automatic tapping machine embodies many new features and as it runs at a speed never obtained by hand machines, it is a great time saver. The spindle is arranged so that by an adjustable stop on the upper end it is tripped and reversed automatically at any point in the operation. The screw machine shown is the smallest size built and is complete with wire feed, spring collet chuck, cut-off cross slide, revolving turret, oil pot, friction countershaft, etc.

Printed matter and catalogues of their large line of lathes,

planers, shapers, drill presses, milling machines, turret lathes, gear cutters, wire coilers, profilers, cutter grinders, die slotters, presses, shears, etc., are distributed by Mr. H. W. Holbrook, who is in charge of the exhibit.

Steam Specialties Exhibited in the Generating Section.

OUR illustration below shows a corner in the generation section in the basement and includes the following exhibits: The Nonpareil Cork Mfg. Co., described elsewhere; L. Katzenstein & Co., showing their metallic packing for pistons and valve stems, flexible tubular metallic packing, metallic gaskets and slip joints for steam pipes; Adam Cook's Sons, exhibiting samples of Albany cylinder, machinery and dynamo oils, ammonia cylinder and olive oils; the Monarch Manufacturing Co., whose exhibit will be described later; the William S. Haines Co., exhibiting the well known Heintz steam traps, thermo regulators and thermometers; Keiley and Mueller, showing a great variety of Keiley specialties, such as reducing valves for all purposes, all kinds of steam traps, cham-



ONE CORNER OF THE STEAM APPLIANCE EXHIBITS IN THE BASEMENT.

pion return steam traps and boiler feeder, positive acting pump governing water pressure regulator and water feeder, improved climax damper regulator, multi-tubular oil and grease extractor, improved steam separators, standard tubular water arch for steam boilers and the Empire drain trap; the Vacuum Oil Company, showing a great variety of lubricating oil and compounds; the Consolidated Safety Valve Co.'s, the Hayden & Derby Mfg. Co.'s and the Ashcroft Mfg. Co.'s joint exhibit of steam engine and steam boiler attachments and gauges described in a previous issue; the Borne, Scrymser Company, showing samples of sperm engine, cylinder, brilliant machinery and high pressure Arctic machinery oils. Adjoining this exhibit are the headquarters of the National Association of Stationary Engineers, whose meetings are held every evening in the rooms adjoining the Concert Hall.

Various Other Exhibits.

THE INDIA RUBBER AND GUTTA PERCHA INSULATING CO., manufacturers of the well known Habirshaw wire and cables, have an exhibit to the left on entering the main floor, where are shown in a large glass case numerous different types of cables and coverings manufactured by the company.

THE WARD ARC LIGHT CO. have their booth stationed on the left hand balcony. The various kinds of arc lamps manufactured by the Ward Co. are here exhibited together with the Washington Carbon Company's products. The special feature of this exhibit is the powerful searchlight, which is said to give 100,000 candle power.

THE AMERICAN PULLEY CO., whose factories are situated at Philadelphia, Pa., have an attractive exhibit on the main floor, where they show the different kinds of pulleys which they manufacture. These pulleys are very extensively used throughout the world and have always given entire satisfaction.

THE SAMSON CORDAGE CO. have their exhibit at the rear of the main floor. Trolley and arc lamp cords and ropes together with their other well known products are shown in a handsome glass case, which has attracted the attention of all visitors to the show.

THE WILDAY ELECTRIC ENGRAVING CO. have their beautiful exhibit on the main floor, where they show to the visitors the art of engraving on metals of various kinds. They sell many beautiful souvenirs, such as match boxes and cigar cases, on which they engrave the name of the purchaser free of charge. This exhibit has attracted the attention of every visitor at the show on account of the use of the electric motor for engraving purposes.

THE AMERICAN ECONOMIZER, illustrated herewith, and built and exhibited by Broomell, Schmidt & Co., Ltd., York, Pa., was described and its merits pointed out in our issue

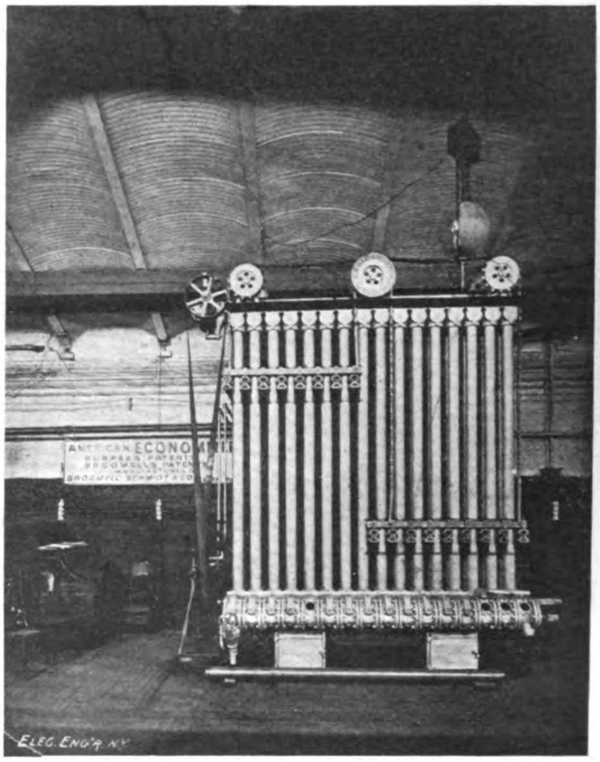


EXHIBIT OF THE AMERICAN ECONOMIZER CO.

of May 5. Since that time the large number of stationary engineers who have attended the Exhibition have manifested a great deal of interest in this fuel economizer and have asked innumerable questions of Messrs. H. Von Mengrenhausen, M.E., and A. P. Broomell.

International Correspondence Schools of Scranton Pa.

ONE of the most interesting features of the Electrical Show is the booth of The International Correspondence Schools of Scranton, Pa., whose New York enrollment office is located at No. 14 East 17th street.

No better proof of the popularity of the methods of instruction employed by this institution could be shown than to see some of their old students taking their friends to have them talked to by representatives of the Schools. The large number of friends they have around them is accounted for by the fact that they have now over 45,000 graduates and students throughout the world.

The correspondence system of education in technical subjects carried on by these Schools, is one of the most successful plans ever devised for giving thorough practical education to wage-earners.

The booth of the Scranton Schools is very attractive. A picture of the school buildings, 5 by 7 feet in size, surrounded by

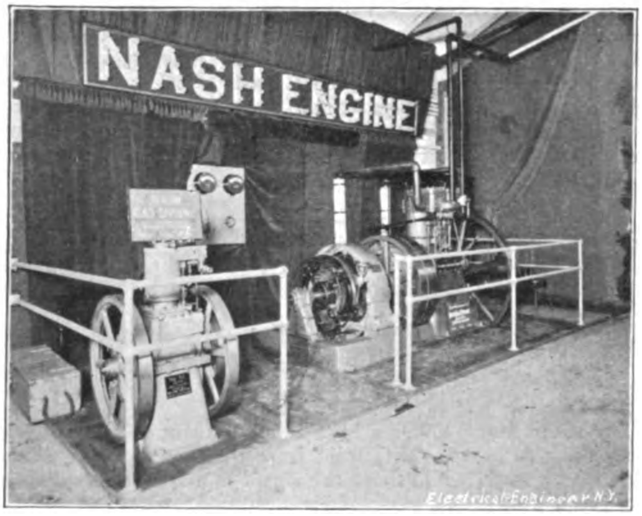
electric lights, showing the picture off to great advantage, hangs at the back of the booth.

The booth is in charge of Messrs. L. S. Harrison, G. J. Mirick and F. S. Lewis, who have been assiduous in their attentions to visitors.

The Nash Gas Engine at the Electrical Exhibition.

THE exhibit by the National Meter Co. in conjunction with the Baylis Company is a 30 horse power vertical double cylinder Nash engine direct coupled to a Walker generator. This exhibit has attracted a great deal of attention on account of the remarkable steadiness of the lights and close regulation from no load to full load. It serves to demonstrate conclusively the practicability of obtaining perfectly steady lights from a direct connected gas engine plant, the results being equal to steam engine practice. The unit shown is representative of a number of plants which have been installed by the Baylis Company in this city and vicinity, several of which have been in operation for the past two years.

The unit exhibited is of 300 lights capacity and occupies a



NASH GAS ENGINE EXHIBIT.

floor space of about 9 x 5 feet. It can readily be seen that such a combination makes an isolated lighting plant possible where lack of space would entirely preclude a steam plant or even a belted gas engine. Running on New York City gas the cost of lighting by means of such a plant is said to be fully 50 per cent. less than the cost of equivalent service from street mains. In the country, where gasolene can be used, the cost of operation is reduced one-half as compared with using city gas as fuel. On a test made at Stevens Institute on a 200 light direct connected Nash gas engine, it was shown that about twice as much light was obtained from incandescent lamps operated from the engine as would result from burning the same amount of gas direct in an ordinary gas burner.

PERSONAL

HON. GARDINER C. SIMS, of Providence, R. I., has been assigned to U. S. S. "Vulcan," and should now be addressed as Lieut. Sims, U. S. N. The "Vulcan" is attached to Admiral Sampson's fleet and her officers and crew are eager for a fight in behalf of Free Cuba. Lieut. Sims has always been prompt to prove himself in every respect a good citizen, and his hosts of electrical friends desire for him a speedy homecoming with many laurels.

MR. HUGO DIEMER has accepted a position with the Westinghouse Electrical and Mfg. Co., at Atlanta, Ga. Mr. Diemer was formerly connected with Diemer & Hebble, representing the Card Electric Co. in the Cincinnati territory.

MISCELLANEOUS

Manufacturers and Dealers in Electrical Supplies in Baltimore—Notes From the Field.—II.

BY C. B. FAIRCHILD.

THE VIADUCT MANUFACTURING COMPANY.

THIS is one of the pioneer telephone manufacturing companies, and still claims to be the second largest manufacturer of telephones, magneto bells, district telegraph messenger boxes, telegraph relays, lightning arresters, and portable police fire alarm and traction telephones, small switchboards for small central stations, etc. Their products go to all parts of this country, to Mexico, South America and Canada. The special claims made for these products are superior material and workmanship, and it is the boast of the manager that they have never had an instrument returned or rejected because of faulty construction.

The main office and store is located on Howard street, while the manufactory is located near the historical Relay station on the B. & O. R. R., nine miles from Baltimore; the name Viaduct is taken from the proximity of the works to the high arch stone viaduct on which the tracks of the B. & O. R. R. cross the Patapsco River.

The buildings are located on the bank of the river at the foot of a high embankment at the south end of the viaduct, as shown some time ago in the pages of The Engineer,

and the tract contains 25 acres of meadow and wild land, in a most romantic and delightful location. The works occupy twelve buildings, including several residences for the men. The works give employment to about 125 hands, many of them being experts in their particular line, some of them having been in the employ of the company for twenty-seven years. For five years the concern was a licensed manufacturer for the Bell Telephone Company.

Water power is employed for operating the machinery, and there are four vertical turbine wheels of the Leffel type. The wheels are located immediately under the building, and operate under a head of seven feet fall, the water coming through a race from a dam located some distance above the viaduct, in quantity sufficient for 200 horse power. The power is transmitted by belts to the main shaft of the power building, and is distributed by belts to the other buildings.

The first, or power, building, is 100 x 40 feet, and to this the

material, consisting of steel bars and brass plates and rods, is delivered. The steel bars are cut up and bent into shape for the horseshoe magnets used in the magneto signal bells. The bars, which are 1¾ x ¼ inch, are cut by means of hand shears into suitable lengths when they are passed through a furnace and after being heated are pressed into shape, when they are tempered and ready to be magnetized, one man being able to bend and magnetize 400 a day. A part of the power building is occupied by the nickel plating department, current for which is derived from a small generator. The burnishing room adjoins this, and the main floor is used for the storage of bars and sheets of brass, of which 300 pounds a day are consumed.

Among the other supplies are batteries, which are bought by the carload, and glass insulators for pole lines. On this floor is an 85-light generator used for the purpose of lighting the works, and a 300-light alternating current generator, which lights the relief office station of the B. & O. R. R., just across the river; there is also a 50 volt generator from which current is used for energizing the permanent magnets. A rotary fire pump and a gas machine complete the equipment of the power building.

The building occupied by the machine shop is 208 x 48 feet, and consists of a main floor and two rooms, one for the packing department and the other for the woodworking machinery. The metal working tool equipment is very complete, there being about 50 small machines, consisting of lathes, screw machines, radial and gang drills, and die punches. Some of the lathes are equipped with an automatic electric device, which rings a bell when a piece of work is finished, so that one man is able to tend three or four machines. The screw machines or turret-headed lathes, having their various tools ready mounted, permit of the cutting of screws and other brass parts very rapidly.

About 35 different types of district telegraph signal boxes are made, some of which are known as "Answer Back" boxes, which give a return acknowledgment signal when a call is made. The output for call boxes is from 8,000 to 10,000 a year, and the capacity for telephones is about 100 a day, complete, including bells, transmitters, receivers and case; recently the company filled an order of 6,000 magneto bells for the Kinlock Telephone Company.

The woodworking department is equipped with a full complement of tools for sawing, planing, dove-tailing and polishing the oak and black walnut for use in making the boxes and cases. Each machine is provided with an exhaust pipe for removing dust and shavings, which are delivered into storage bins outside the room. A kiln for drying lumber stands near the machine shop, and is built of brick.

The finishing department occupies a building 60 x 48 feet, in which the telephone cases are varnished, finished and set up ready for shipment. Nearly all the work in this department is done by hand; there being only one wood-boring machine, which is driven by a C & C motor.

Some of the special features, or rather recent improvement, in the telephones now being manufactured are the use of hard rubber insulation in place of the fibre in the transmitters, and the diaphragm rests against a pocket of carbon shot, finer than that formerly employed, and is known as No. 8. There is a new desk equipment in which the bell is not cut out if the operator fails to hang up the receiver. A special designed stand, with a base switch, is for use in warehouses and building exchanges by means of which any room may be called, but does not prevent another call coming in; it is necessary, however, to adjust the switch properly in order to talk with the new call.

A large number of telephones are now turned out provided with an arm rest, by means of which the contacts are made, the receiver is attached by an ordinary hook, this rests the arm of the operator while talking, and is sure to disconnect when he leaves the box.

Among the specialties are a new portable telephone outfit, which consists of a generator and ringer, receiver of hard rubber, transmitter and one cell of dry battery; the outfit weighs 14 pounds, and is provided with a strap for carrying. This is designed for use by steam and street car conductors, so that they are able to report to the station from any point on the line, contact being made by throwing a wire over the line wire, and making a ground connection, except where metallic circuits are employed, in which case both wires are lassoed.

Another specialty is a Police Fire Alarm and Trolley Signal outfit, in an iron outer shell, for use on poles, in connection with which is used a large vibrating gong, to notify conductors, as they pass a given point, that they are wanted.

Permanent magnets are employed in the motors for operating the call signals, both in the call boxes and telephones, and these after being bent and tempered as described above, are magnetized by being drawn four or five times over the fields of a strong electromagnet, having a core of soft iron, the terminals of which are grooved, and are made adjustable so that grooves of different size may be drawn through them. In constructing the fields of these little motors four horseshoe magnets are employed, the arms of which are from four to five inches in length. These are arranged in pairs, one being inside the other, separated by a short air space. Each pair is laid side by side and fastened at the base with a solid piece on each pole between which the armature revolves. The armature consists of a solid iron core, of peculiar shape, and the wiring is lengthwise, laid in grooves on two sides of the coil. A commutator is placed on the end of the shaft, outside the bearing, and one of the leads from the armature connects with it through the hollow shaft, the other is attached to the case. The gear wheels for a revolving armature are toothed four to one, so that ordinarily in ringing, the armatures make 800 revolutions a minute.

Mr. A. G. Davis, president of the company, is an old-time telegraph operator, having received his first lessons in 1849 from his cousin, the late Samuel F. B. Morse, the father of telegraphy. In his earlier career as a telegraph operator he was stationed two years at Poughkeepsie, N. Y., and afterwards went to Canada and built all the telegraph lines of the Grand Trunk Railway.

THE BALTIMORE CAR WHEEL COMPANY.

This firm are extensive manufacturers of chilled car wheels of all sizes, for steam or street railway service, they also manufacture trucks, both single and double, for electric or cable cars, car axles and chilled brake shoes.

The works are located in the city, near Fulton Junction, at intersection of Pennsylvania and Western Maryland railway tracks, so that sidings from both roads lead directly into the yards, offering excellent shipping facility.

The shops stand under a high bluff of an open tract of land, containing 22 acres. This tract is really a park, being shaded with native trees, while there are shrub bordered walks dividing the green sward. A handsomely designed, large and commodious office building of cut stone is delightfully located at the highest point, some distance back from the main building.

On a high tower near the office is a large tank into which the city water flows, and from which, through an eight-inch main, it is distributed about the buildings for fire purposes, the natural head being sufficient to throw the water 25 feet above any of the buildings.

The machine shops proper occupy two main buildings, that for the machine tools is 66 x 100 feet, two stories in height, while the foundry building is of one-story, 66 x 375 feet, and both are covered with slate roofs. The tool equipment consists of wheel-borers, axle lathes, wheel presses, and such iron working tools as are usually employed in shops of this character, with sufficient wood-working tools for pattern making, etc.

The foundry is provided with two Colliot cupolas, which occupy wings set off from the main shop, and which have a capacity for melting 100 tons of iron per day, or making 400 car wheels per day. The main floor is equipped with numerous cranes for handling the chills and flasks, and for placing the wheels in the annealing pits, which occupy a large space in the floor near one end of the foundry.

The truck department occupies portions of both buildings. The Lord Baltimore type of truck is here manufactured, by which the company is probably as well known, as from their car wheel products. In the construction of this truck, which is illustrated in the accompanying engraving, the side frames are made in one piece, from 4 x 5-inch steel Tee beams forged into the required shape by hydraulic pressure. The frames are reinforced at the bearing points by cast steel yokes 30 inches in length, which carry the journal boxes, and which are accurately fitted to the side beams, having a bearing at top and bottom, and when in place are leaded, making practically a solid weld. The yokes are formed with side pockets which carry graduated spiral springs that rest on the axle box wings, and so carry the entire weight, including motor and truck, making the truck particularly easy on rail joints.

A peculiar and desirable feature of these trucks is the shape and arrangement of the body springs, no spring bolts being employed. These consist of six half elliptical springs, three on each side, as shown in the illustration, and each 36 inches in length; these are flexibly attached to the side frames in such a manner as to prevent all teetering and provide for an unusually long car body. The link attachments for supporting the springs are of cast steel, as are all the adjustable parts of the truck, except the wheels and brake shoes. These spring hanger supports are milled and carefully fitted to the frame; those for the middle spring being first spread and then closed upon the Tee beams and bolted, while those for the end springs are slid over the end of the side beam after being fitted. These, as well as all other parts, are so arranged that no part can fall to the ground should the bolts be removed.

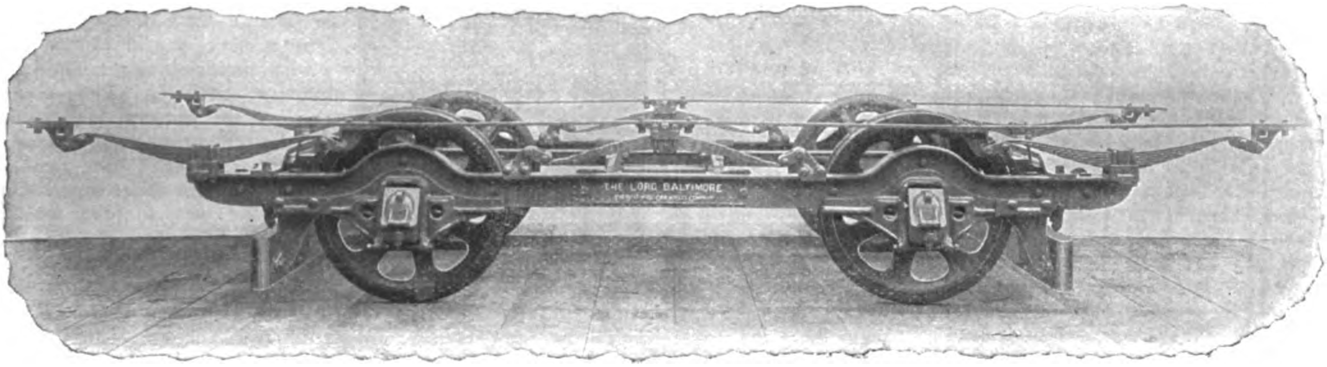
The brake mechanism is of the equalizing type, and all connecting rods are placed above the axle so that no part of the brake mechanism is disturbed when removing or replacing wheels and axles. A convenient method of brake rod adjustment is provided, consisting of a lock nut and split key, which can be manipulated without putting the car over a pit. All pivoted points in the brake levers are provided with case hardened bushings, and the pins, which are of rolled steel, are hardened and pressed in. The end cross bar, which is of rolled steel, serves to brace the truck, the brake equalizing and brake beams are reinforced at the middle with a cast steel plate, which partly embraces the bars and are provided with lugs which support the hardened pins on which the brake-lever is pivoted. Tests show that this bar will stand a load of 17,000 pounds without apparent deflection.

The method of motor suspension is unique, and is easily adjusted, while the axle collar is particularly novel. For this the thimble is pressed on the axle, but carries at its inner end a split ring or collar, which is threaded to the thimble. This split ring is provided with lugs on one side, through which bolts are passed, and when the nuts are turned up hold it firmly in place. Should the collar or face of the motor bearing wear, the collar can be loosened and turned on the thimble, thus bringing it out to any adjustment, when it is again tightened up. The journal box, which is of a special design, manufactured only by this firm, is provided with a hinge cover, but dovetailed to its seat, and drawn down by means of a bolt and nut at the under side of the box. To open the box the nut is loosened when the cover can be slid up slightly and then turned back on its hinges, but it cannot fall off, or be lost on the road.

The double trucks manufactured by this firm are of original design, but are built with the same degree of care as the single trucks. Half elliptical springs are also employed on the double truck, and these are arranged in pairs on each side beneath the bolster, one above and one below the side frames, and are connected by a plunger. Provision is made for leading the brake chain through a case provided within the body centre bearing in which guide wheels are placed, which insures a direct centre pull on the brake beam in all positions, and avoids the use of a compensating yoke or quadrant.

The brake rods are attached to a lever by interlocking devices, which require no pins to hold them in place, so that they are readily detached when it is necesary to remove the truck from the cars. The brake rods are above the axles, as is the case on the single truck.

The single trucks weigh about 5,200 pounds, but when equipped with inside brakes 5,400 pounds. The company manufactures a special type of inside brakes, having a rack and pinion adjustment, and which may be applied to cars that operate over excessively steep grades. The particular claims made by the firm for their trucks are superior material and workmanship, giving great strength, with comparatively few parts, and little or no cost for mainainance.



LATEST FORM OF THE LORD BALTIMORE STREET CAR TRUCK.

MECHANICAL

Receiving Well and Water Tunnel of Allegheny County Light Company, Pittsburgh, Pa.

THIS tunnel is constructed of brick and is circular in shape, having an inside diameter of four feet. The bricks are laid on edge, two deep, with the long sides parallel with the tunnel. At the river end the entrance is through a grating made of iron bars 1½ inches by 2 inches, and placed ¾ inch apart, the ½-inch side facing out. This grating is held by a heavy mass of concrete, foundation of which is laid in the river bed.

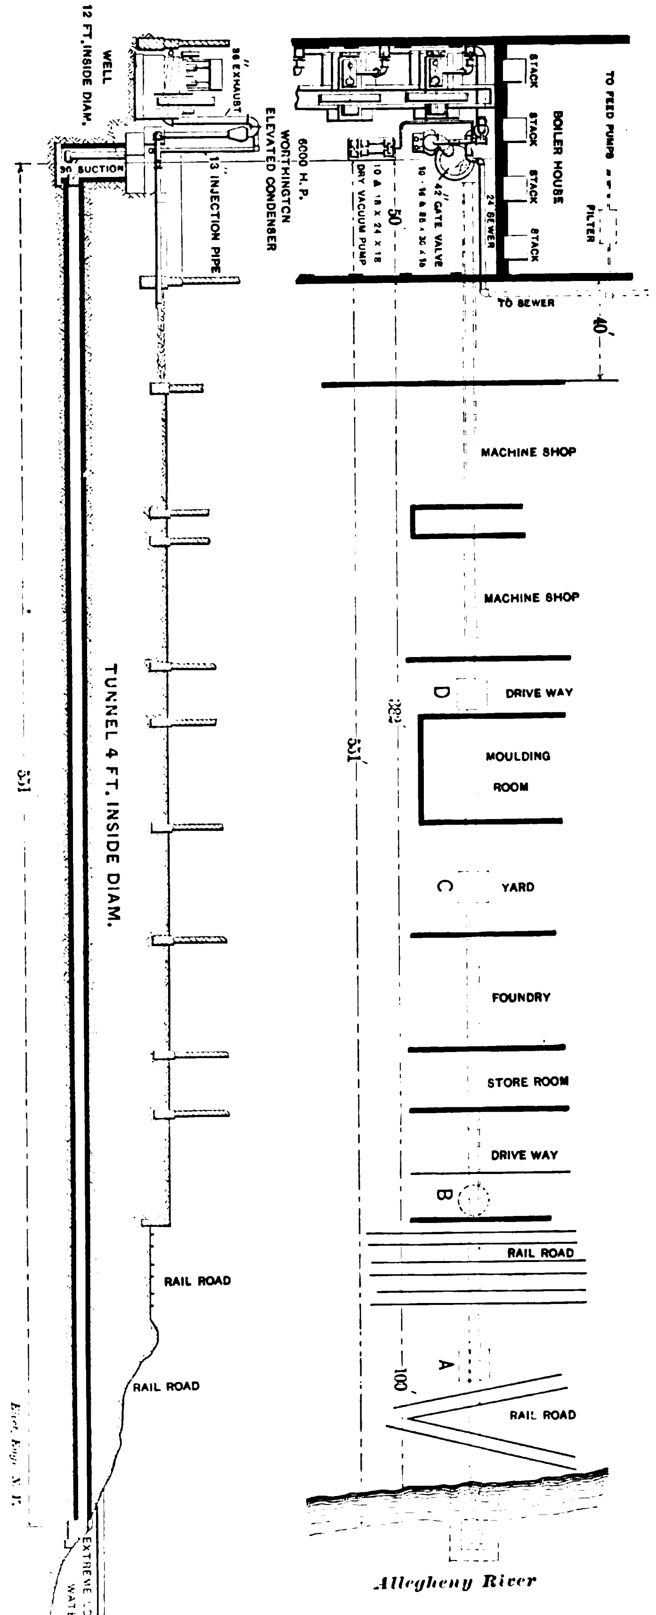
The circular brick arch which forms the tunnel proper starts inside of the mass of concrete and passes under the Junction R. R., McIntosh & Hemphill's plant, and Etna street, a distance of 550 feet, at a depth of about 40 feet from the surface, and ends in a receiving well in the engine room of the Allegheny County Light Company, as shown on the accompanying diagrams.

The entrance to the receiving well is made through a 42-inch gate valve bolted to the end of a cast-iron nozzle which projects through the side wall into the well, the other end of the nozzle being built into the brick work of the tunnel. The receiving well is 12 feet in diameter, and drops from the level of the pump pit floor to a depth of 3 feet 10 inches below the bottom of the tunnel, forming a pocket to allow for the accumulation of sediment from the water. The bottom of the well is of concrete 2 feet 6 inches thick; this also forms the foundation for the side walls, which are of brick and are 18 inches thick.

The location of the circulating pump is such that it was necessary to bring in the opening from the tunnel to one side of the centre (see diagram) to allow room for the screen to pass between the foot valve on the end of the suction pipe and the 42-inch inlet valve. The screen is made in four sections, each section consisting of a yellow pine frame covered with a net of No. 11 galvanized iron wire with a ¾-inch mesh. These sections are held in place by strips of iron which fit loosely into grooves cut in the side pieces of the frames. The strips of iron are bolted to upright pieces, which are in turn supported by cross timbers built into the brick walls of the well. When it is necessary to remove the sections they are slid up and down these strips of iron guided by the grooves in the sides of their frames.

As the river often rises 25 feet above low water mark, and as the level of the pump pit and basement floors would be several feet below the water level at such times, a heavy watertight oak flooring was built around the suction pipes, closing completely the opening of the well, thus preventing the flooding of the lower portions of the plant at high water.

The water for condensing purposes is drawn from the well through a 30-inch cast-iron suction pipe by a 10-16 x 25 x 30 x 18 Worthington vertical pump. After passing through the condenser, a portion of the water is run through a filter and is used in the boilers.



RECEIVING WELL AND WATER TUNNEL, ALLEGHENY COUNTY CO.'S PLANT.

Work was begun at the place marked "A" on the drawing by making an open cut to the river; the tunnel was started from the bottom of this cut. The open cut was dug deeper than the bottom of the tunnel to act as a sumpt to catch any water that might drain through from the heading until the tunnel would be connected to the intake in the river. In this cut was placed a centrifugal pump capable of throwing 2,400 gallons per minute, which kept the water under control.

A shaft was then sunk just inside of McIntosh, Hemphill & Co.'s property, and the tunneling was started from the bottom of both shafts marked "A" and "B." A third shaft was sunk at "C," from the bottom of which the tunneling was started towards "B." It was also started from "B" towards "C." At this time another shaft was sunk at "D," and the work of building a coffer dam around the place in the river where the mass of concrete which forms the intake was to stand.

At this stage of the progress the water became so high in the river that it was impossible to keep the water low enough in the tunnel to allow the men to work. The whole length of the tunnel lies in sand and gravel, some of the sand being a mild form of quicksand through which the water from the river seeps rapidly, necessitating constant pumping. The character of the ground necessitated bracing and sheathing in all tunnels and shafts. After the water took its normal level in the river, work was resumed by starting to dig the well in the engine room. No difficulties were encountered until the work reached a distance of 12 feet from the bottom, when it was found that the sand came in under the sheathing almost as fast as it could be taken out.

SOCIETY & CLUB NOTES

New York Electrical Society Election and Dinner.

President G. S. Dunn.

At the Electrical Exhibition on Thursday evening, the New York Electrical Society held its annual meeting. The reports of the treasurer, Mr. H. A. Sinclair, and the secretary, Mr. G. H. Guy, were read and unanimously accepted. The society was shown to be in sound financial shape and to be growing rapidly. The nominations of the Executive Committee for the officers to serve during the ensuing year were then read, and there being no other nominations, the ticket was adopted with applause. The lecture by Prof. Short, on "Electric Traction," was then proceeded with, Mr. H. B. Coho being in the chair.

The newly elected officers of the Society are: President, Gano S. Dunn; Vice-Presidents, W. E. Case, H. B. Coho, Dr. C. A. Doremus, F. A. Pattison, E. E. Higgins, Chas. Blizard; Secretary, George H. Guy; Treasurer, Henry A. Sinclair.

President Gano S. Dunn has been an active and useful member of the society for some time past and has merited the promotion from the vice-presidency. Mr. Dunn, who is chief engineer of the Crocker-Wheeler Co., is a graduate of the City College and of Columbia University, taking his E.E. degree at the latter in 1891, with very creditable prominence. He has since then paid special attention to design, and his Society lecture on dynamo and motor design has been in constant demand. Mr. Dunn is also an active member of the American Institute of Electrical Engineers. His deep interest in the welfare of the Electrical Society promises it a continuance of the new growth and prosperity it is enjoying.

On Friday evening the society gave a dinner at the St. Denis Hotel, when about 100 members and guests sat down. The dinner was excellently served, the room was tastefully decorated with flags and the tables with flowers, and music was furnished by a small band. Speeches were made as follows: "The New York Electrical Society," Pres. Gano S. Dunn and Secy. G. H. Guy (the latter playing an original composition of his own instead of making a speech); "The American Institute of Electrical Engineers," Prof. F. B. Crocker; "The Technical Colleges," Mr. Joseph Wetzler; "The Yankee Militant," Capt. E

L. Zalinski, U. S. A.; "Sister Societies," Dr. W. McMurtrie; "The Newspaper Man," Mr. S. L. Coles; "Electrical Applications," Mr. F. W. Jones (first president of the society in 1881); "The Electrical Manufacturer," Mr. H. Ward Leonard; "What we Think of Electrical Engineering," Messrs. C. O. Mailloux, for the consulting engineer, and Mr. H. B. Coho, for the electrical contractor. The speaking was brief in each case, but remarkably effective and interesting, and many noteworthy things were said. The proceedings were freely interspersed with music, and the party joined in heartily when national and patriotic airs were played. Altogether the evening was very delightful and marked another stage of advance in the society's history.

Programme of the N. E. L. A. Convention.

WE give below the official programme of the Chicago convention of the National Electric Light Association:

Tuesday, June 7, 1898.—Meeting of the Executive Committee at 9 a. m., secretary's office, Auditorium Hotel. Morning session, 10.30 o'clock, Convention Hall, Auditorium Hotel. Address, President Insull. Paper, Calvin W. Rice, Brooklyn, N. Y., "Cost of the Generation and Distribution of a Unit of Electricity." Topic, "Prices and Discounts for Electric Current and Methods of Billing Current to Customers." Afternoon session, 2 o'clock.—Paper, Alex. Dow, Detroit, Mich., "Public Lighting with Relation to Public Ownership or Control." Topic, "Legislative Policy as to Public Service Corporations."

Wednesday, June 8, 1898.—Morning session, 10 o'clock.—Paper, Herbert A. Wagner, St. Louis, Mo., "General Distribution from Central Stations by Alternating Currents." Paper, Louis A. Ferguson, Chicago, Ill., "General Distribution from Central Stations by Direct Currents." Topic, "Standardizing Apparatus for Central Station Use." Afternoon session, 2.30 o'clock.—Paper, W. McLea Walbank, Montreal, Canada, "Cost of Producing Electric Power by Water Power from Lachine Rapids, Canada." Report, Committee on Standard Candle Power of Incandescent Lamps, Dr. Louis Bell, chairman. Questions and Answers. What Is It You Wish to Know? Executive session. Evening session, 8 o'clock, Auditorium Hall. —Lecture, Joseph Wetzler, "Electricity Direct from Coal" (illustrated with stereopticon).

Thursday, June 9, 1898.—Morning session, 10 o'clock.—Paper, Prof. W. E. Goldsborough, "Transformer Economy." Report, Committee on Amendments to Freight Classification, James I. Ayer, chairman. Report, Committee on Legislation Concerning Theft of Current, James I. Ayer, chairman. Afternoon session, 2.30 o'clock.—Topic, "Freight Rates on Electrical Apparatus." Report, Committee on Finance, James A. Seely, chairman. Executive session. Election of officers.

Prof. S. H. Short Before the N. Y. Elec. Soc.—Electricity Applied to Heavy Railway Service.

DESPITE the abominable weather a large audience assembled in the Concert Hall at the Electrical Exhibition on Thursday evening last to hear Prof. Short lecture before the New York Electrical Society on "Electricity Applied to Heavy Railway Service," and all who came were well repaid for braving the storm. In simple, popular language, but with close precision of date and detail, Prof. Short told the story of the art making it fresh and vivid and so plain that the veriest layman could see how the art had grown and evolved.

Prof. Short went back to the early work of Thomas Davenport and Davidson, and then by rapid stages came down to the great developments which began with his own work and that of Henry, Van Depoele, Daft, and others in the early eighties, with both overhead and under car conductors, until Sprague with his great coup at Richmond convinced the street railway managers that the time had come for the vital change. Prof. Short then noted the next great step forward, namely, the present transition or extension going on, from the ordinary street car service to the cross country system. Attention was called particularly to the development in this respect around Cleveland and to the work at Mason City, Iowa, with a line handling all classes of traffic.

This brought Prof. Short to the competition of the electric road with steam and the beginning of the present era in which the electric motor is slowly but surely eliminating the steam locomotive. He drew attention first of all to the elevated and suburban electric work in and around Chicago, and the development of the modern third rail system and then came down to date with the work on the Brooklyn Bridge and Brooklyn Elevated and that now proposed for the Manhattan system. Then he turned to the wider aspects of this subject by describing and illustrating the work of the New York, New Haven and Hartford Railroad on various branches and sections of main line, and paid a deserved compliment to President Clark and Col. Heft for their boldness and success in grappling with the problems of applying the third rail to regular steam lines.

Prof. Short closed his admirable review of the subject by a luminous discussion of long electric roads and the means for feeding them with current, such as the use of the alternating current with static converters and rotary transformers. He pointed out how the perfection of a synchronous motor would simplify many of the present difficulties; but under any circumstances the reign of electricity on long roads was sure and certain.

The lecture was profusely illustrated by lantern slides under the direction of Mr. Anthony, of the Walker Co., and also was noteworthy as being inclusive of the first kinetoscope pictures ever shown of electric trains in motion at Hartford, Conn., and on the Brooklyn Bridge, in contrast with steam roads. They were received with great applause, the absence of the big clouds of smoke, steam, dust, etc., being very striking. At the close of the lecture, chairman Coho conveyed the thanks of the meeting to Prof. Short for his admirable lecture.

Transportation to the Chicago N. E. L. A. Convention.

We are in receipt of the following from Mr. C. O. Baker, Jr., Master of Transportation:

As already announced, the various passenger associations have granted a rate of a fare and one-third, on the certificate plan, for delegates and their friends attending the Chicago convention, to be held June 7, 8, 9. Arrangements have been made to have the New York delegation leave Grand Central Station Sunday, June 5, via New York Central, Hudson River & Michigan Central R. R., leaving at 1 p. m., on New York, Boston and Chicago special train; Poughkeepsie, 2.43; Albany, 4.20; Schenectady, 5.05; Utica, 7.03; Syracuse, 8.35; Rochester, 10.47; Buffalo, 11.50 p. m., central time; Detroit, 8.00 a. m., arriving in Chicago 3 p. m. Monday. The train leaving Boston at 10.30 a. m. Sunday, June 5, will connect with this train at Albany. This being a limited train, an excess fare of $1 is charged, therefore the railroad fare is $21 and the berth rate $5, making a total of $26. In purchasing tickets, delegates should be particular to obtain a certificate from the agent from whom the purchase is made, as in the absence of such certificate no rebate can be allowed on the return passage. In case the number of delegates attending should warrant, a special train will be run as a second section of the train named. Tickets can be procured at any ticket office of the New York Central Railroad, and space reserved by applying to either the undersigned or to M. C. Roach, General Eastern Passenger Agent New York Central & Hudson River R. R., 413 Broadway, New York.

The Trip to the Northwestern Convention.

Mr. J. M. Hill, of Chicago, informs us that the "Northwest" will leave Chicago at noon on the 10th for the trip up the lakes, and all inquiries as to staterooms, etc., should be addressed to him at 1240 Monadnock block. He says:

"We leave Chicago as originally planned at noon of the 10th, putting in to Milwaukee for such of our members who desire to take the steamer there instead of coming to Chicago. We stop a few hours at Mackinac Island, thence going to Sault Ste. Marie, where we arrive at 5 p. m. on Saturday. The steamer first lands on the Canadian side to inspect the furnaces above referred to, the big plant of the Tagona Company and other points of interest. We are then brought back to the American side, and there will be a formal programme furnished by the citizens of the city on Saturday evening. We remain at this place until Sunday noon, living on board the steamer, utilizing Sunday morning for the inspection of the big locks and ship canal, the carbide works, etc. We arrive at Hancock about 4 a. m. Mon-

day and will be taken early Monday morning to the Calumet and Hecla mines, where we stay until about 2 p. m. During this time the ladies of our party are to be taken care of by the citizens of Hancock and Houghton, the two cities being practically together. We arrive at Duluth on Monday night about 9 p. m., where a great reception is to be given us. A paper on the 'Electrical Smelting of Ores' is to be read at Duluth by Mr. W. S. Horry, and there is to be a varied entertainment furnished by the citizens of that city. The banquet is to be held at West Superior on Tuesday night, and is given by the citizens of both Duluth and Superior. It is to be one of the most elaborate affairs ever given in the West and is to be attended by some very notable men. We leave via special train, stopping some three hours in Minneapolis for the inspection of the new big power plant of the Twin City Rapid Transit Co., and will probably have dinner at the West Hotel, leaving Minneapolis about 8:30 p. m. and arriving at Chicago early on the morning of the 16th."

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued May 24, 1898.

Alarms and Signals:—

ELECTRIC SIGNAL FOR RAILWAY CROSSINGS. L. C. Smith, Columbus, O., 604,431. Filed May 18, 1897. Means whereby danger signaling bells are automatically rung by a passing train, where roadways cross railway tracks.

SECONDARY ELECTRIC CLOCK. A. D. Blodgett, Newton, Mass., 604,453. Filed May 29, 1897. Details of construction.

ELECTRIC CLOCK. W. Whitehead, Manchester, England, 604,508. Filed June 7, 1897. Details of construction.

Batteries, Secondary:—

ACCUMULATOR PLATE. I. Rosler, Berlin, Germany, 604,418. Filed March 10, 1898. Consists of a continuous zigzag core piece, the surfaces of which on both sides are fitted with triangular webs wholly separated from each other.

STORAGE BATTERY. H. S. Lloyd, Philadelphia, Pa., 604,588. Filed Dec. 23, 1896. Comprises a vessel having vertically disposed passages formed by partitions arranged at the sides of the vessel for the escape of any excess of electrolyte and for the passage of the connecting wires.

Dynamos and Motors:

DRIVING MECHANISM FOR DYNAMOS. P. W. Alexander, Allapaha, Ga., 604,511. Filed Sept. 21, 1897. The rotation of the axle of a car is utilized for the running of a dynamo located within the car.

Measurements:—

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 604,460. Filed March 29, 1897. An alternating current induction motor-meter operating by the inductive action of two magnetic fields of differing phase upon a closed secondary or armature.

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 604,640. Filed Aug. 6, 1897. Similar to above.

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 604,461. Filed Aug. 6, 1897. Similar to above.

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 604,462. Filed Aug. 11, 1897. Consists of an annular armature of low electrical resistance, series coils within the armature arranged on separate axes on opposite sides of the axis of the series coils, and a magnetic field acting at right angles to the axis of the series coils for the purpose of overcoming the friction of the meter.

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 604,463. Filed Aug. 26, 1897. Comprises a revoluble metallic armature, and a series of field coils without armature whose adjacent poles are in close proximity thereto, and in such relation that the resulting intersecting lines of magnetization are at right angles to each other; in combination with an equal number of volt coils located within the armature whose lines of magnetization are inclined to the lines of magnetization of the field coils.

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 604,464. Filed Sept. 11, 1897. Combines series coils connected in series in the main line and conveying the current to be measured, with a pair of shunt coils arranged within the series coils, and a revoluble metallic armature mounted within the shunt coils.

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 604,465. Filed Sept. 24, 1897. An integrating wattmeter of the motor type.

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 604,466. Filed Nov. 8, 1897. An integrating wattmeter for measuring alternating electric currents.

MOTOR WATTMETER. C. D. Raab, Kaiserslautern, Germany, 604,501. Filed Dec. 27, 1897. Comprises a disc armature, two horseshoe electromagnets placed near each other at one side of the disc armature and a main current solenoid at the other side.

Miscellaneous:—

VALVE CONTROLLING DEVICE. W. S. Alexander, New York, 604,358. Filed Feb. 24, 1896. A valve of large capacity is controlled through the operation of a valve of small capacity, by the use of a motor operated by the pressure controlled by the main valve and regulated electrically.

ELECTRIC HEATER. E. E. Gold, New York, 604,384. Filed Oct. 14, 1897. Comprises an insulating open work support consisting of a thin foraminous tube, and a helix of resistance wire wound helically around the support, whereby air may circulate about all portions of the heated resistance wire.

ELECTRIC BRUSH. E. M. Hellwig, Chicago, Ill., 604,471. Filed Dec. 11, 1896. A battery is placed within the handle and suitable contacts are provided.

ELECTRICAL LIGHTING DEVICE FOR KEROSENE OR OTHER BURNERS. S. M. Meyer, Brooklyn, N. Y., 604,626. Filed Jan. 27, 1897. Details of construction.

Regulation:—

ELECTRICAL GOVERNOR. M. A. Replogle, Akron, O., 604,544. Filed Feb. 10, 1897. Comprises an electrical governor having a pair of electromagnets, a pair of insulated electrical contact points by means of which electrical circuits may be completed through the magnets, the insulating contact points being separately adjustable and jointly movable.

Switches, Cut-Outs, Etc:—

AUTOMATIC RESETTING FUSIBLE CUT-OUT. J. D. Holmes and W. L. Heath, St. Louis, Mo., 604,616. Filed April 12, 1897. Comprises a rotary member, radial fuse holding arms pivotally mounted thereon to swing in radial planes, the rotary member being normally locked against rotation, and means for releasing it when a fuse is burned out.

Telegraphs:—

COMBINED TRANSMITTER AND RECEIVER. J. M. Joy, New York, 604,533. Filed June 21, 1897. Of the "page printer" class. Details of construction.

Telephones:—

AUTOMATIC TELEPHONE EXCHANGE. W. Decker, Owego, N. Y., 604,373. Filed March 25, 1895. Electrical impulses are caused to operate a step-by-step movement to connect a terminal of one line to a terminal of another line.

TELEPHONE SIGNAL SYSTEM. W. A. Stilwell and A. Barneck, Salina, Kan., 604,434. Filed Nov. 10, 1896. A series of subscribers' stations are connected with a central station, and means are provided whereby any one subscriber can connect his telephone with any other subscriber at will.

MULTIPLE TELEPHONY AND TELEGRAPHY. R. Pfund, New York, 604,499. Filed Oct. 22, 1897. Details of construction.

Vacuum Tube Lighting:

INCANDESCENT ELECTRIC LAMP REGULATOR. D. McF. Moore, New York, 604,679. Filed Feb. 10, 1892. Consists of the combination with the filament thereof, located within an evacuated bulb of circuit breaking terminals outside of the bulb in free air, and means for automatically maintaining vibration of the terminals relatively to and from each other.

ELECTRIC LAMP REGULATOR. D. McF. Moore, New York, 604,680. Filed Oct. 13, 1894. Similar to above.

INTERRUPTER FOR ELECTRIC LIGHTING SYSTEMS. D. McF. Moore, Newark, N. J., 604,681. Filed Dec. 3, 1895. Comprises an interrupter loosely pivoted in a sealed receptacle, an armature borne thereby, and a pair of actuating magnet poles arranged on opposite sides of the magnet being in circuit independent of the interrupter contacts.

MAGNETIC CIRCUIT BREAKER. D. McF. Moore, Newark, N. J., 604,682. Filed Sept. 8, 1896. Designed for use in vacuum tube lighting systems.

MAGNETIC CIRCUIT BREAKER. D. McF. Moore, Newark, N. J., 604,683. Filed Sept. 8, 1896. Means to utilize each half vibration of the contact tongue to effect an interruption of a circuit.

AUTOMATIC VIBRATORY INTERRUPTER. D. McF. Moore, Newark, N. J., 604,684. Filed Dec. 17, 1896. Comprises an operating magnet in the circuit, including the interrupter contacts, and a jarring device for insuring continuous action of the interrupter.

ELECTRIC LIGHTING APPARATUS. D. McF. Moore, Newark, N. J., 604,685. Filed Feb. 15, 1897. Comprises a rotary circuit interrupter working in a sealed receptacle, designed to secure a very rapid and uniform rate of revolution of the inclosed parts of the device without rotation of exterior masses surrounding the receptacle and without the use of motor commutators within the inclosed space.

APPARATUS FOR PRODUCING LUMINOUS OR SIMILAR EFFECTS. D. McF. Moore, Newark, N. J., 604,686. Filed July 3, 1897. Comprises a circuit interrupter in an exhausted receiver, a magnet for the operation of the interrupter and devoid of inductive effect upon the circuit, and a separate magnet acting inductively upon the circuit, the operating and inductive magnets being placed in branches of the circuit, but both in circuit with a contact of the interrupter.

CIRCUIT INTERRUPTING MECHANISM. D. McF. Moore, Newark, N. J., 604,687. Filed Sept. 9, 1897. Comprises a vacuous receptacle, a circuit interrupter therein, a motor for driving the interrupter also located in the receptacle and having the coils thereof insulated by and thoroughly imbedded in a vitreous mass.

CIRCUIT INTERRUPTER. D. McF. Moore, Newark, N. J., 604,688. Filed Sept. 10, 1897. Consists of a metallic foundation and sections of porcelain which have a fused or fired connection with the metal.

THE STOCK MARKET

The Tale of a Fleet.

The course of the markets may be said to have waited on events in the Caribbean Sea and the disposal of Adml. Cervera's will-of-the-wisp fleet, but doubt as to the Spaniard's position cannot last forever. Meantime stocks have been steady and strong, though a trifle dull. Western Union closed on Friday at 91¼, and General Electric at 36⅜.

Copper, New York, is quoted at 12 cents, and heavy steel rail, Eastern mill at $18 per ton.

BERLIN IRON BRIDGE CO., of East Berlin, Conn., have just completed a fireproof boiler house for the Hendey Machine Company, of Torrington, Conn.

TRADE NOTES & NOVELTIES

Ericsson Telephonic Head Gear and Breastplate.

The accompanying cut represents the latest Ericsson pattern of head gear and breastplate for switchboard, field, marine and army purposes. The old type of head gear, which the Ericsson Telephone Co. have been selling for the past year, has been greatly improved upon. The advantage is that an operator has both hands free at all times to operate the board, thereby making the service much more rapid. In addition to this, the company are equipping the breastplate with their new knuckle joint head gear and receiver, which conforms with the unevenness of the ear and assists the operator very greatly in adjusting. It also prevents any outside sounds from passing through the ear drum. This is a very valuable feature, and will be appreciated by any operator. Instead of using the lever contact by throwing the microphone forward in a speaking position, it automatically makes its contact. The Ericsson Co. make these of four different types, with differentially wound coils or direct circuits. The whole plate complete, with head gear and receiver, weighs about the same as the ordinary head gear, all being light aluminum plates. Their 1898 catalogue is just about ready for distribution, and the company will be pleased to send it out to anyone on application to their address, 20 Warren street, New York City.

The Thermo Electric Co.

This is the name of the new company just organized to manufacture and sell the improved Cox thermo electric generators under an exclusive license from the patentee.

The president of the new company is Colonel Augustus G. Paine, one of the best known and ablest business men in New York, and who was last year mentioned as a candidate for the Greater New York mayoralty. Colonel Paine is a member of the Union League Club, president of the New York and Pennsylvania Co., who operate enormous paper and pulp mills; a director of the New York Life Insurance Co., the Mercantile National Bank, and many other institutions prominent in the business and financial world.

The company's general manager is Mr. L. S. Langville, a gentleman of marked business ability, who may be depended upon to prove that the thermo electric generator is a factor to be reckoned with among small electric power sources. Mr. Merle J. Wightman is the consulting electrical engineer of the company and Mr. Otto Rothenstein, superintendent of the factory.

The company has fitted up extensive and fully equipped new shops, where they are now turning out in large quantities the Cox thermo electric generators, into which a number of improvements have been introduced, looking to still greater economy and convenience in use. It is now ready to deliver on receipt of order two types of thermo electric generators, each giving 6 watts on closed circuit. The first of these generators gives 5 volts on open circuit and 4 amperes on closed circuit; the second gives 10 volts on open circuit and 2 amperes on closed circuit.

These types of generators are specially adapted for the running of electric fans, for operating local telegraph sounders, for electric bell work, for driving phonographs, for galvanoplastic work, such as gold and silver plating. These thermo generators are also exceedingly well adapted for charging storage batteries for use by dentists, for operating automatic pianos, for X-ray work, etc., in fact, wherever a small and constant source of current is required.

The offices of the Thermo Electric Co. are at No. 102 Times building, New York.

The Warren-Medbery Co.

In our last issue, in describing the new Warren-Medbery inductor alternator, an error of the types located the factory of the Warren-Medbery Co. at Sandy Hill, N. J. It should have read Sandy Hill, N. Y.

PHILADELPHIA NOTES

THE WESTINGHOUSE ELECTRIC and Manufacturing Company is building two three-phase belt driven generators, 500 h. p. each, 3,000 alternations, 2,400 volts, for the Canadian Niagara Power Company at Niagara Falls. The success of the 5,000 h. p. machines built for the Cataract Construction Company has encouraged others to enter the field for harnessing Niagara, who, like the pioneers, come to the Westinghouse Company for the apparatus.

WESTERN NOTES

WESTERN ELECTRIC CO. has issued bulletins as to its alternating current fan motors and arc dynamo regulators, which will be sent to any address.

THE BOULDER ELECTRIC LIGHT CO., Boulder, Colo., who already have a number of Ball engines in satisfactory use, have recently ordered from the makers, the Ball Engine Co., Erie, Pa., a 100 horse power engine arranged for direct connection to a 60 kilowatt General Electric machine.

MR. GEO. M. MAYER, who, it will be remembered, was connected with the Electrical Engineering Department of the World's Fair as chief draughtsman, has been established the last three years in Chicago. He has a model and machine shop making a specialty of developing electrical inventions.

THE PERUNA DRUG MFG. CO., Columbus, Ohio, have recently ordered from the Ball Engine Co., Erie, Pa., and the Siemens-Halske Electric Co., Chicago, two 150 horse power Ball engines direct connected to 75 kilowatt generators, and one 225 horse power engine direct connected to a 150 kilowatt generator.

THE JANDUS ELECTRIC COMPANY report many inquiries for and sales of their enclosed alternating arc lamp. The special points of merit are high efficiency, noiseless, steady burning, and long life. Catalogue and prices will be furnished on application. The Chicago office of the Jandus Electric Co. is at 753 Monadnock Bldg.

THE WESTERN ELECTRIC COMPANY has issued a twenty-four page pamphlet on tools, which contains a most complete list of linesmen's and construction tools, all of which can be furnished from stock. Everyone interested in the construction of electric lines should have a copy and the Western Electric Company will mail one upon request to any one desiring it. This pamphlet is known as Tool Catalogue No. 3.

MR. S. J. WICK, of the Electric Railway Equipment Co., has been in the East recently and has established a factory for building poles at Reading, Pa., which is now in successful operation and working full time. During the month of April alone, 100 carloads of poles were shipped from the Reading factory, and another recent order which Mr. Wick has procured is the individual order of 3,500 poles for the city of Mexico.

THE ELECTRIC APPLIANCE CO. have recently closed a general Western agency arrangement for Armorduct interior conduit, the latest product of the Armorite steel armored interior conduit. The Armorduct is a steel tube heavily enameled inside and outside by a special and exclusive process. The enamel placed on this tube gives a perfectly smooth interior

with a coating which will withstand a temperature of 500 degrees. Bending and twisting the tube will not crack or break the coat of enamel. Further than this the enamel is absolutely proof against the action of cements or acids of any description. The Electric Appliance Company have a very valuable specialty in their Armorduct, and large sales are prophesied.

NEW YORK NOTES.

A FINE ATLAS has just been issued by the American (Long Distance) Telephone and Telegraph Co., the inside pages having excellent large colored maps, while telephonic lines across the United States are shown on the covers. It is is very judicious and timely piece of enterprise.

ADVERTISERS' HINTS

THE VIADUCT MFG. CO., Baltimore, Md., are advertising a telephone outfit for traction systems. It is designed with a view to rough service and durability, and undoubtedly is a success in these points as well as containing many other desirable features.

FOUR HUNDRED WHEELS PER DAY is the capacity of the Baltimore Car Wheel Co., Baltimore, Md. This company is the manufacturer of the "Lord Baltimore" truck and also the Blakistone automatic fender and wheel guard, which has been approved by special municipal commissions.

THE MARYLAND TELEPHONE MFG. CO., 11-13 East Lee street, Baltimore, Md., advertise the Minnis system of telephones and switchboards and the Brown loud-speaking transmitters. Beside the above, they mention new types of intercommunicating and interior sets.

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, Ill., claim to have the latest thing in interior conduit. This is "armorduct," a heavy steel tube enameled inside and outside by a special process. They say the coating of enamel will not crack in bending, is not affected by acids or currents and remains hard in all temperatures up to 500 degrees.

THE GORDON-BURNHAM BATTERY CO., 594 Broadway, New York, advertise battery fan outfits complete with cabinet connecting cords, etc., and capable of running 150 hours without a renewal of the battery.

LORICATED CONDUITS form the subject of the Central Electric Co.'s "ad" this week. It is described as a hole with an anti-rust ironclad armor, which protects the wire, keeps the current in and the moisture out, and is easy to install. They are carried in their stock at 264-270 Fifth avenue, Chicago.

THE AMERICAN ELECTRIC TELEPHONE CO., 171-173 South Canal street, Chicago, Ill., state that over 500 exchanges use their instruments, aggregating over 100,000 telephones.

THE EDDY ELECTRIC MFG. CO., Windsor, Conn., illustrate their type "G" motors and generators. They are built in sizes ranging from 5 h. p. to 30 k. w., have cast steel magnet frame, self-oiling bearings, laminated armatures, cast copper segments in commutators, and have brush holders of either tangent or radial type using carbon brushes.

THE ELECTRIC STORAGE BATTERY CO., Drexel building Philadelphia, Pa., announce that the New York Edison Co. has contracted for a third battery of "chloride accumulators." It will number one-hundred-fifty cells of 4,000 ampere hours' capacity.

THE CROCKER-WHEELER ELECTRIC CO., 39 Cortlandt street, New York, advertise power generators.

THE STROMBERG CARLSON TELEPHONE MFG. CO., 72-82 West Jackson boulevard, Chicago, advertise complete telephone equipment for all classes of service.

THE NORTHERN ELECTRIC MFG. CO., Madison, Wis., advertise a large variety of dynamos and motors to suit all classes of service.

THE WESTINGHOUSE ELECTRIC AND MFG. CO., Pittsburg, Pa., call attention to their generators for electrolytic work, of which they claim there are more in use than of any other make.

Anchor Electric Co., vs. Horatio C. Hawkes.

A decree for the plaintiff has been ordered by the full bench of the Supreme Court of Massachusetts in the case of the Anchor Electric Co. vs. Horatio C. Hawkes, where the plaintiff in seeking to specifically perform an agreement made by the defendant, asked for an injunction to restrain him from interfering or competing with it in its business for a period of five years from Sept. 29, 1894. Though the agreement was not limited as to territory, and the plaintiff's business extends over the whole country, the court holds that it is a valid agreement, going no further than is reasonably necessary for the protection of its business, and is not void as in restraint of trade. The agreement was made upon the sale by the defendant of his interest in the Hawkes Electric Co. and the consolidation of this company with the Iona Manufacturing Co. and the Brown Electric Co., by the formation of the plaintiff. All officers of the old companies signed the agreement, and the court holds that it went no further than was reasonably necessary to protect the good will of the defendant's corporation, and is enforceable against him.

This case was decided some time ago by Judge Holmes and has now been reviewed by the Supreme Court as noted above.

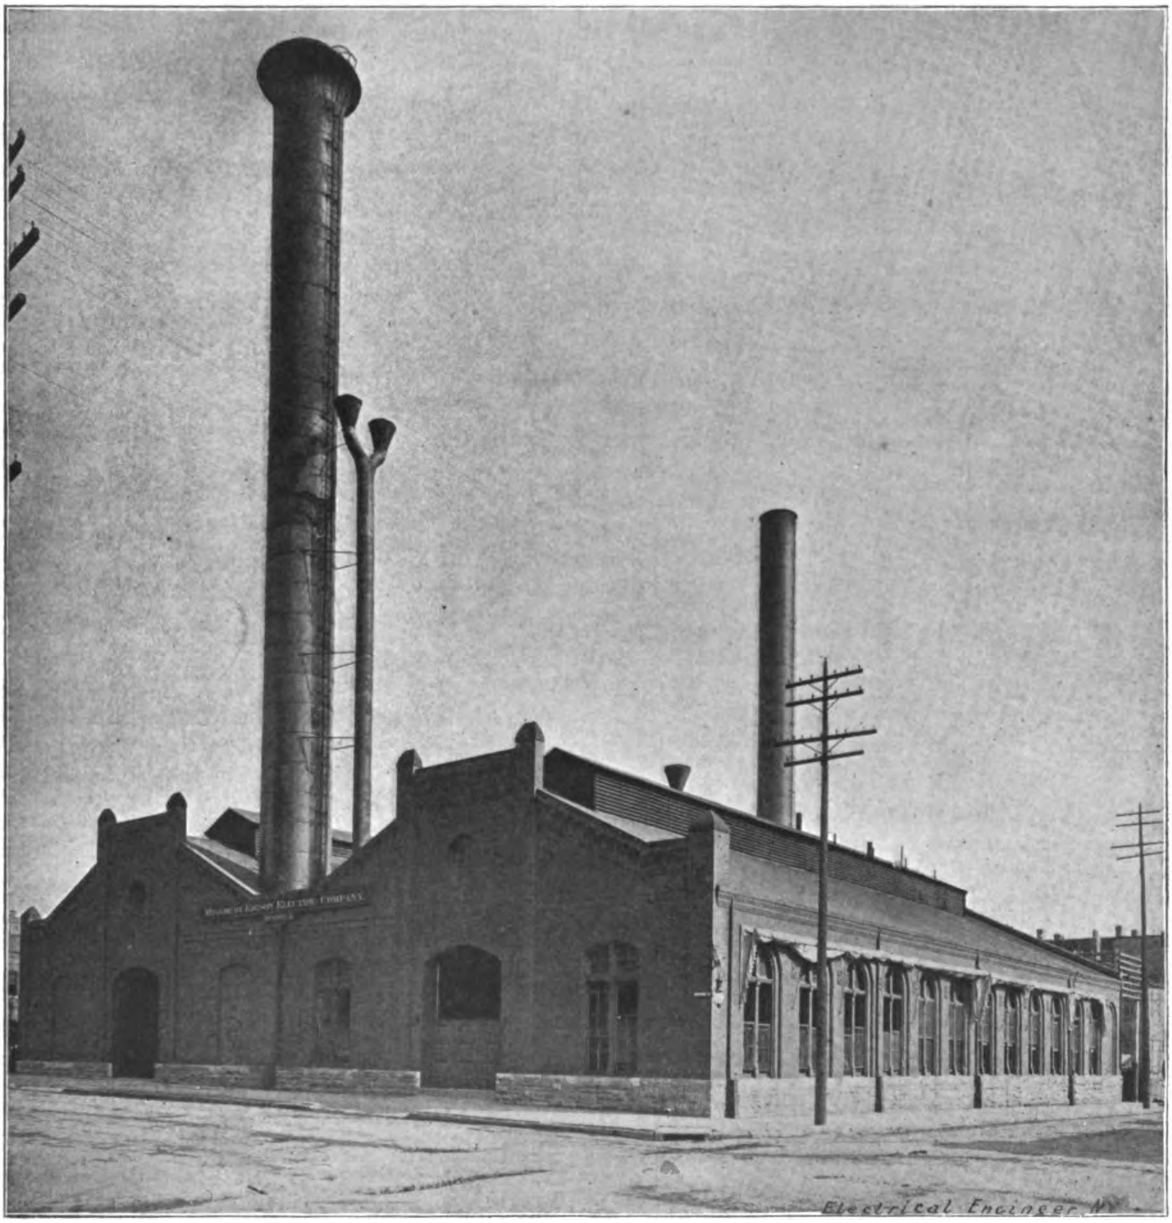
The Electrical Engineer.

Vol. XXV. JUNE 9, 1898. No. 527.

THE MISSOURI-EDISON ELECTRIC COMPANY OF ST. LOUIS, AND ITS DEVELOPMENT OF THE ALTERNATING CURRENT SYSTEM FOR LIGHT AND POWER DISTRIBUTION.

BY HERBERT A. WAGNER.

"ELECTRICITY is in its infancy." How often one hears this expression among that great body of laymen to whom nothing is too wonderful for electricity to accomplish. To those, however, who have acutally followed closely the growth of this infant during the last ten years it must really appear a very precocious child. Almost before Mr. Edison and his co-laborers had perfected a system for the distribution of light and power from central stations, the electrical world was startled by the announcement of the work of Messrs. Gaulard and Gibbs with their alternating current transformer system and the quickly following development by the Westinghouse Electric Company of a comprehensive system of distribution by alternating currents early in the year 1887.



STATION "A," MISSOURI-EDISON ELECTRIC CO., ST. LOUIS, MO.

Since that time the inventions of Tesla and others have so broadened the range of possible adaptations of the alternating current that the future of electrical development would seem to be within its pulsating grasp.

While the manufacturers were busy perfecting new electrical and motive apparatus and devices, it was left to a few pioneer central station companies to develop and perfect the details for the practical distribution of electricity to all parts of a large city and for the various purposes there required. Foremost and largest among these alternating current central stations is the Missouri-Edison Electric Company, of St. Louis. The work which this company has been quietly doing in the last few years has quite recently been causing much comment, and engineers

from all parts of the country are looking to St. Louis as one of the leaders in alternating current distribution for meeting the demands of the industrial and commercial life of the modern city.

The early struggles of this company to obtain apparatus and devices suitable to the requirements of its business and its efforts to assist the manufacturers to improve and perfect the comparatively crude machinery of those embryonic days would fill a good-sized volume, and can therefore only be briefly mentioned here.

HISTORY AND DEVELOPMENT.

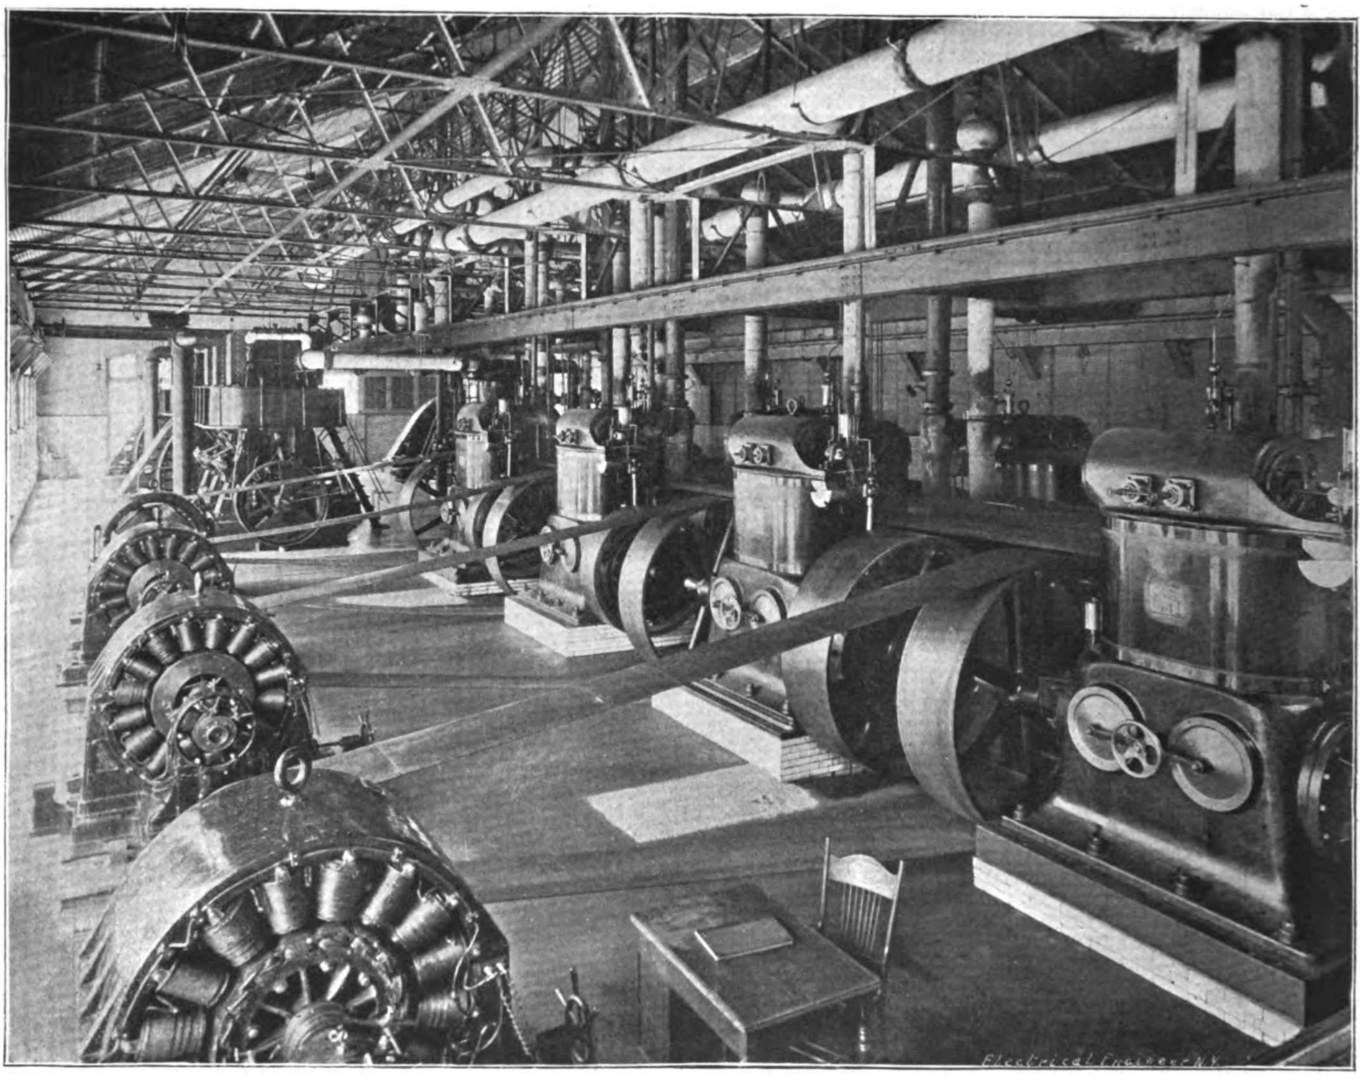
It was shortly after the construction of the first commercially practical alternating current transformers that the writer and a representative of the Westinghouse Electric Company went to St. Louis to endeavor to establish an electric light plant. At that time the practical utility of the alternating current was still looked upon with suspicion, and the low tension advocates were not at all wanting in energy to strengthen and maintain that suspicion.

After much uphill work, the influence of such men as Mr. S. M. Dodd, Mr. J. C. Van Blarcom and others associated with them was secured, and under their able leadership the necessary capital was subscribed, and early in the year 1889 the Missouri Electric Light and Power Company was organized and the construction of its station begun.

All the electrical apparatus for this original installation was bought from the Westinghouse Electric Company, and was of a total capacity of 10,000 16 c. p. lamps. The plant was started in August of the same year and by the end of that year the success of the company seemed assured. The original capital stock was $600,000, and $600,000 of bonds were issued. At the end of the first year the company had 18,910 incandescent lamps connected to its system.

On January 1, 1890, the company entered into a contract with the city of St. Louis for lighting the alleys, public places and buildings throughout a large section of the city at fairly good prices.

The business of the company grew at a rapid rate, and at the end of the second year there were connected to its lines 32,508 incandescent lamps. Station generating apparatus was added from time to time, and the company soon began to pay dividends at the rate of 8 per cent. per annum. The following table shows the increase of the company's business and that of its successor, the Missouri-Edison Electric Company, from 1890 up to the present year:



ENGINE ROOM FROM SWITCHBOARD SHOWING OLD 175 K. W. GENERATORS AND 1,000 K. W. GENERATOR IN BACKGROUND, STATION "A."

" " 1898	174,265	3,575	1,036	2,390

Early in 1893 the Edison Illuminating Company, of St. Louis, was organized and soon acquired the property of the Municipal Electric Light and Power Company. This latter company had been organized late in 1889 for the purpose of carrying out a contract with the city of St. Louis to light the greater portion of its streets with arc lamps, and the business of the company consisted principally of this and commercial arc lighting, a small

amount of power being furnished from 500-volt generators and a few thousand incandescent lamps being operated from the alternating current system.

In December, 1893, the interests of the Missouri Electric Light and Power Company and the Edison Illuminating Company, of St. Louis, were practically consolidated, although the two companies retained their individual names and corporate existence and continued to be operated independently, but under the direction of the same officers.

In 1897 the Missouri-Edison Electric Company was organized for the formal consolidation of these two associated companies. and soon after the new company also acquired the property and business of the St. Louis Electric Light and Power Company.

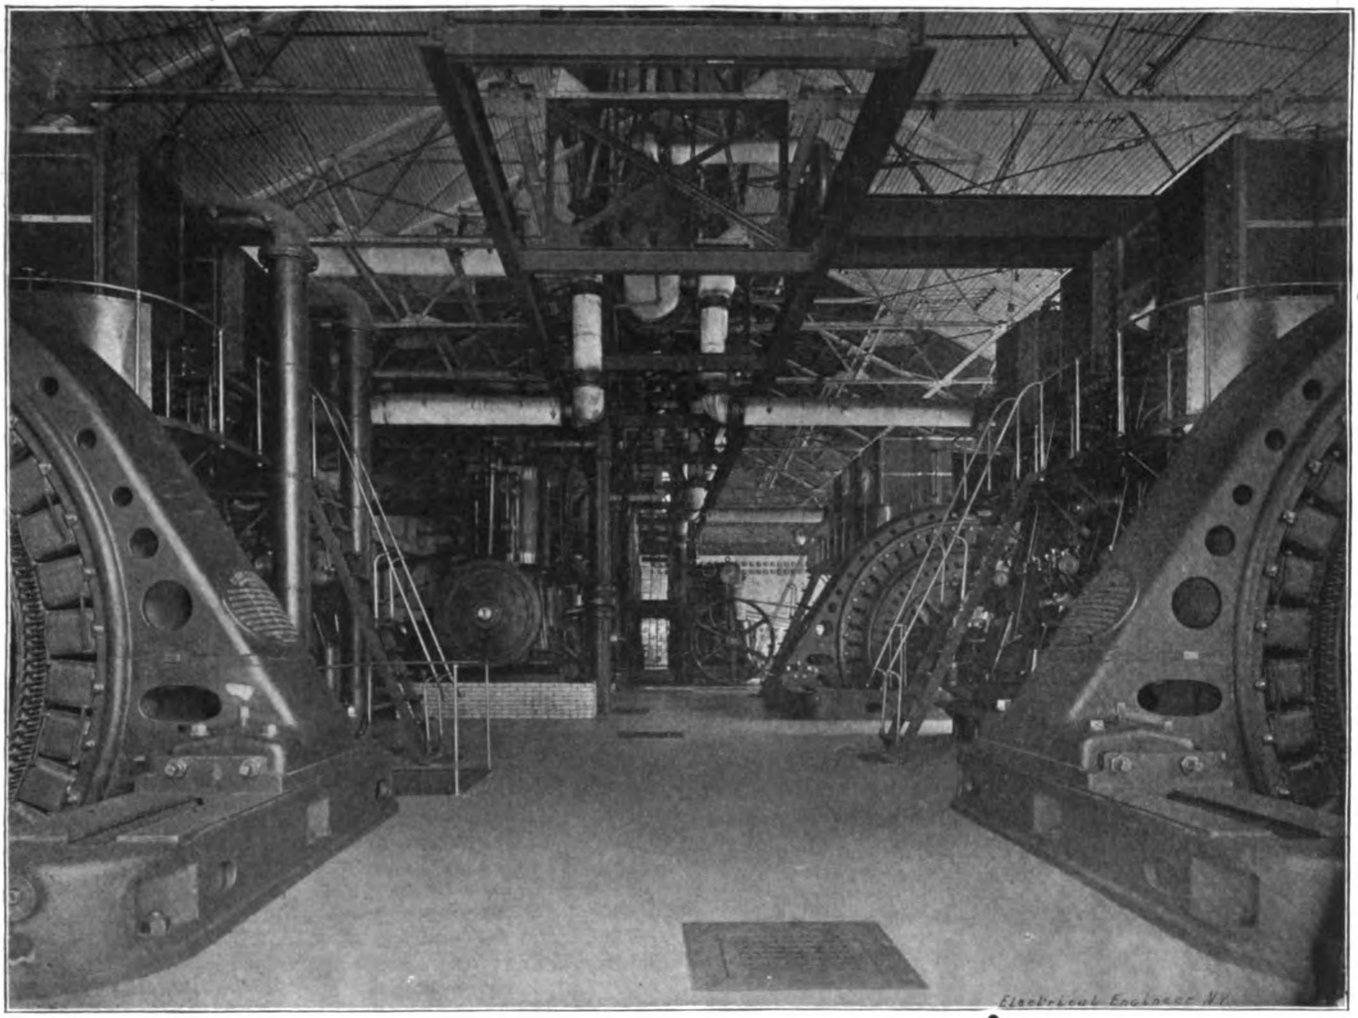
The stations of these several companies before any consolidation took place had steam and generating capacities as follows:

Missouri Electric Light and Power Company, 1893: Engines, 4,100 h. p.; alternating current generators, 40,000 16 c. p. lamps.

Edison Illuminating Company, of St. Louis, 1893: Engines, 4,800 h. p.; alternating current generators, 12,000 16 c. p. lamps; arc light generators, 4,500 arc lamps; 500-volt power generators, 280 k. w.

St. Louis Electric Light and Power Company, 1897: Engines, 1,100 h. p.: alternating current generators, 3,600 16 c. p. lamps; arc light generators, 420 arc lamps; power generators, 440 k. w.

These stations have since all been remodeled and are now known as stations "A," "B" and "C" respectively.



VIEW IN STATION "A," LOOKING TOWARD SWITCHBOARD THROUGH CENTRE OF ENGINE ROOM.

STATION A.

This station was the one originally built by the Missouri Electric Light and Power Company. The building is 135x155 feet, being divided longitudinally into two rooms, one 152x63 feet, containing engine and generator plant and switchboard; the other 152x67 feet, containing the boiler plant. The construction is of brick and stone, with iron and slate roof. The building is of one story and 35 feet high.

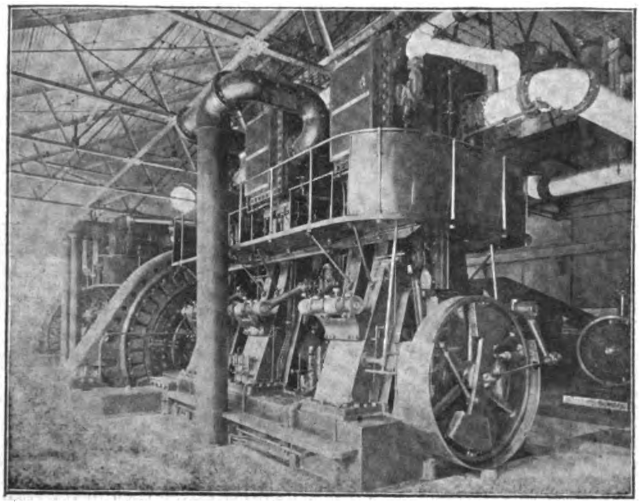
The generating apparatus of this station now consists of three 1,500 h. p. three-cylinder compound engines, built by the Lake Erie Engineering Works, direct coupled to three 1,000 k. w. alternating currents generators, built by the Westinghouse Electric and Manufacturing Company on the designs of the writer; one 600 h. p. Westinghouse compound engine belted to one 350 k. w. Westinghouse alternating current generator; six 300 h. p. Westinghouse compound engines belted to six 180 k. w. Westinghouse alternating current generators; two 300 h. p. Westinghouse compound engines belted to two 200 k. w. 500-volt power generators; three 120 h. p. Westinghouse compound engines direct connected to two 75 k. w. Westinghouse 125-volt direct current generators and one 100 k. w. General Electric 125-volt direct current generator, all three being used for exciters. The steam is generated by eighteen 240 h. p. Babcock & Wilcox boilers, built by the Babcock & Wilcox Company.

GENERATORS.

The 1,000 k. w. generators are designed to operate at a speed of 180 revolutions per minute and deliver current at a pressure of from 1,100 to 1,300 volts at a frequency of 60 cycles. They are of the stationary field type, being similar in design to the modern direct current railway generator of large size, the commutator, of course, being replaced by collector rings. The winding is so designed that these machines may be used either single phase or two phase as desired, the entire amount of copper being utilized in circuit when operated in either way. The rating of these generators is based on their single phase capacity, but a large margin for overload was provided in their design, and they are regularly operated for several hours per day during the winter months at an output of 1,200 k. w. each. With this load

the rise in temperature of all parts of the machines is hardly appreciable.

The armatures are ten feet in diameter and weigh about 80,000 pounds, providing ample fly-wheel capacity within themselves without any additional wheel. The mechanical features of each of these generators are so arranged that the entire field frame may be moved in a direction longitudinally with the shaft, by means of suitable screws, to a position where the armature is



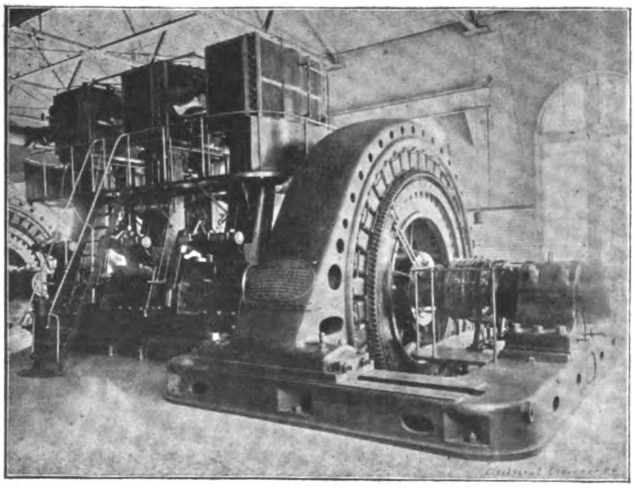
1,500 H. P. LAKE ERIE ENGINE DIRECT CONNECTED TO WESTINGHOUSE 1,000 K. W. GENERATOR, STATION "A."

completely uncovered for inspection and repairs and where field coils may be removed from the pole pieces with ease.

The belted generators are of the general type manufactured by the Westinghouse Electric and Manufacturing Company several years ago. They have stationary fields, and the armatures are of the ironclad type with polar projections. These generators also deliver current at a pressure ranging from 1,100 to 1,300 volts.

ENGINES.

The engines, being provided with three cylinders, distribute the power through three cranks placed at angles of 120 degrees, insuring very uniform angular velocity. With this disposition of cranks and the large fly-wheel capacity provided in the armatures, the variation in angular velocity through different portions of each revolution is less than one-quarter of 1 per cent.



1,000 K. W. WESTINGHOUSE GENERATOR AND LAKE ERIE ENGINE, STATION "A."

This great refinement is unnecessary in direct current practice, but is most essential for the proper operation of alternating current generators in multiple arc.

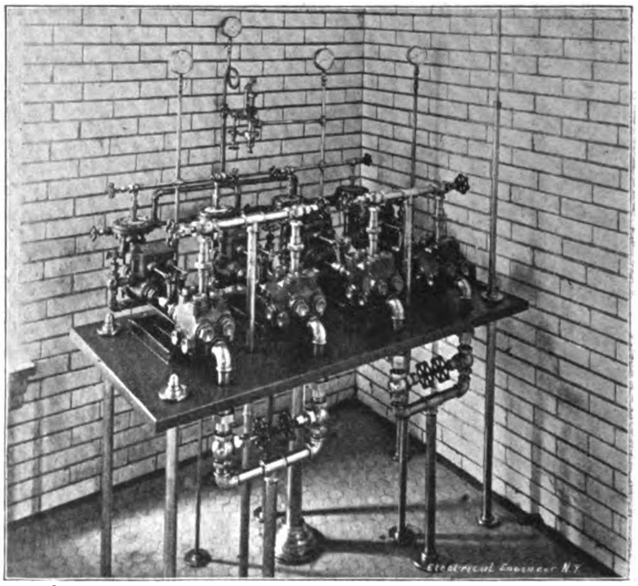
The regulation of the engines is effected by governors of the shaft type, but of special design. Connected to the rocker arm operating the high pressure admission valve on each engine is a double acting air compression cylinder. This acts as an inertia balance to arrest the motion of the valve at the end of each stroke, storing up energy, which is delivered to the valve again on beginning the new stroke. The two ends of this compression cylinder are connected to each other through a by-pass pipe and hand valve, by means of which the amount of compression can be controlled at will. The effect of this inertia balance is to relieve the governor of a great deal of the pressure which would be thrown upon it at certain portions of each revolution. By varying the amount of relief to the governor afforded in this way, by means of the by-pass valve, the speed of the engine may be varied between 5 and 10 per cent. A very effective and accurate means is thus provided for adjusting the engine speed, or causing this speed to remain the same with various loads. This inertia speeding device is the invention of Mr. F. M. Rites, of Ithaca, N. Y.

EXCITERS.

The exciters are of the recent type of direct coupled direct current multipolar generators built by the Westinghouse and General Electric Companies. Each is of a capacity sufficient to excite the fields of all tne generators in the station; two relays, or spare generators, therefore, being ready at all times in case of accident.

BOILERS AND SMOKESTACKS.

The boilers are of the usual Babcock & Wilcox type, and were designed for and are operated at 150 pounds pressure. The furnaces are designed for hand-firing, numerous experiments with mechanical stokers having proved them to be undesirable.



SIEGRIST LUBRICATING SYSTEM, PUMP TABLE, STATION "A."

The smoke and products of combustion are led through underground flues to two steel smokestacks, one 150 feet high by 10 feet in diameter, and the other 135 feet high by 8 feet in diameter. These stacks are bolted at the base to massive concrete foundations, rendering them self-supporting and capable of withstanding the highest wind pressures. They were both built by Riter & Conley, of Pittsburg, Pa., who also provided all the iron work for the roofs.

OILING SYSTEM.

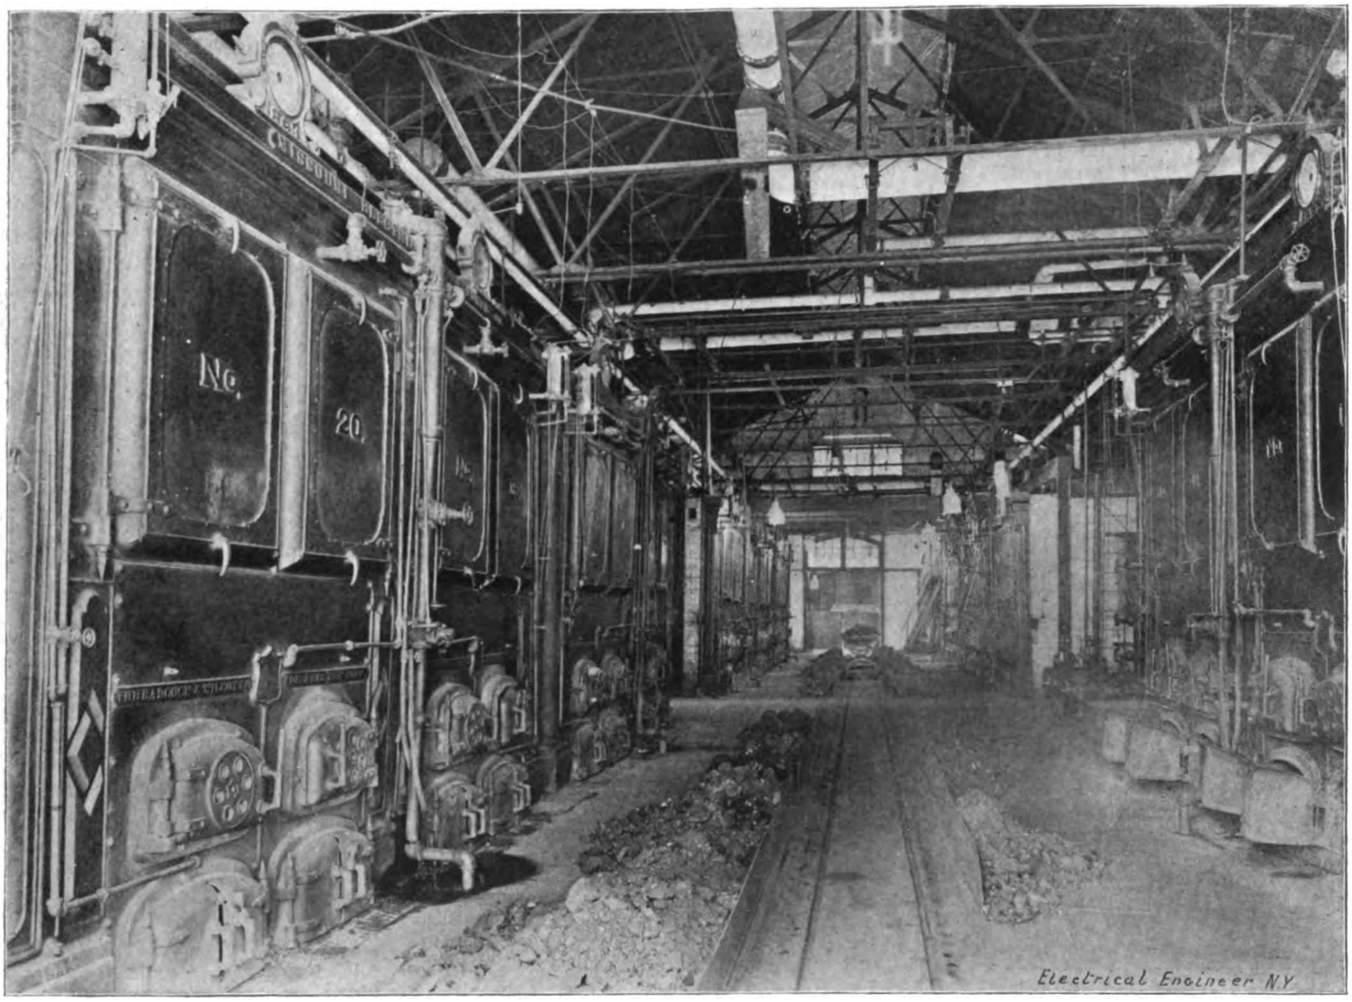
A very ingenious but simple and effective system of oil distribution has been recently installed. This system was designed by the Siegrist Lubricator Company, of St. Louis. Occupying a small space in a corner of the engine room is a slate-topped table holding four of the smallest sized Worthington duplex pumps. These pumps are connected in pairs, one of each pair being reserved as a relay; one pair being designed to pump engine and lubricating oil and the other cylinder oil.

Through suitable piping these pumps are connected to tanks and filters located in the basement. The engine oil is pumped to all necessary parts of each engine and generator at a pressure of 80 pounds per square inch, this pressure being maintained constantly throughout the oiling system, no matter how much or little oil is being used, by means of suitable regulating valves

placed in the discharge pipe of each pump and acting to close or open the steam admission.

At each bearing or part to be oiled is located a sight feed oil cup connected to the oil pipe system. The rate of speed of each oil cup can be regulated at will by a thumb screw provided for that purpose, but a diaphragm pressure valve in each cup instantly closes the oil drip if the pressure in the system is lowered more than two or three pounds. One globe valve placed in the supply pipe for the oil system of each engine is, therefore, sufficient to start or stop all the oil cups in that engine. On closing this valve the oil is stopped within a few seconds at every oil cup whether located on the highest or lowest part of the engine, thus precluding any waste of oil after the engine is stopped. The oil is piped back from all the drips of engines and generators to filters located in the basement.

The cylinder oil is handled in the same way through sight feed lubricators for each cylinder placed at a convenient height from the floor for observation and regulation. The pressure maintained in the cylinder lubricating system is, of course, slightly higher than the steam pressure.



BOILER ROOM, STATION "A," MISSOURI-EDISON ELECTRIC CO., ST. LOUIS, MO.

SWITCHBOARD.

Not the least noteworthy part of this station is the large switchboard. This is built of white Italian marble and is 58 feet long and 16 feet high. It is constructed with two floors at different levels and a liberal basement is provided for cables, rheostats and feeder regulators. The upper portion of the board provides room for 56 feeders and the lower portion will accommodate all the the apparatus for regulating and controlling 15 generators. The board is so designed that all generators may be operated in multiple arc and cut on or off the bus-bar system as the demand for current requires, or each generator may be operated independently of all the others and the feeders grouped at will on any generator desired. The utmost flexibility of operation is thereby provided for. The feeders may be switched at will from any one of the generator busses to any other, or to the general multiple bus without interrupting the current for more than a fractional part of a second. This result is secured by providing individual busses for each generator, in addition to the general multiple bus, to which each generator can be connected if desired.

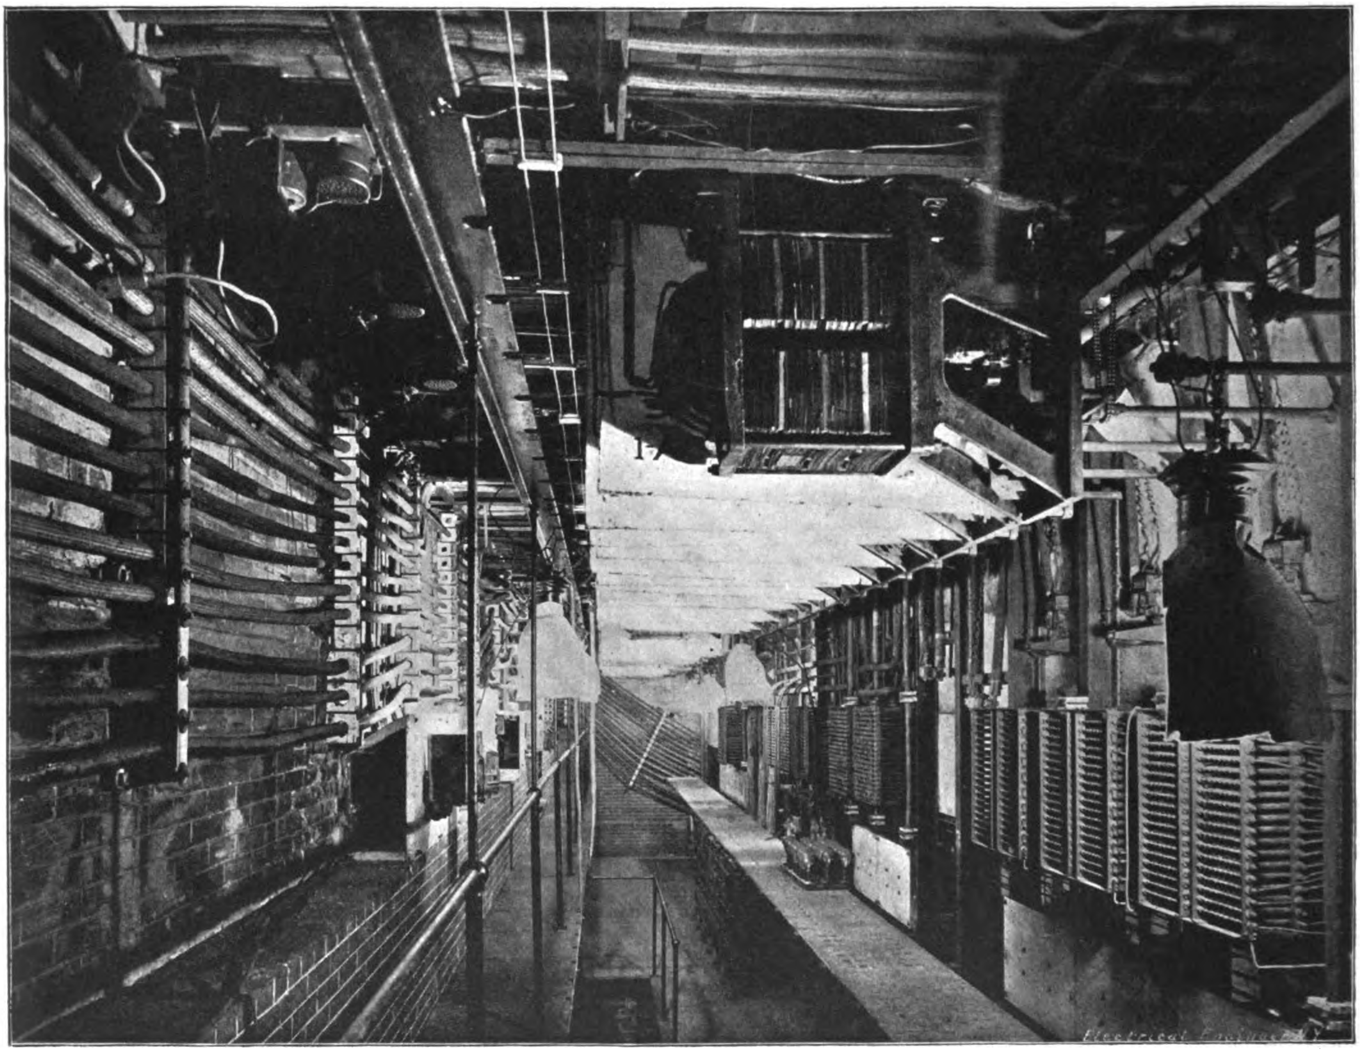
One terminal of each feeder is brought directly to a general bus located on the station wall, to which bus each generator is also connected, and the other terminal of each feeder is brought to a switching device, by means of which it can be connected to any individual generator bus, as already stated. These single pole generator busses are placed on the switchboard proper and the opposite poles are, therefore, separated from each other by a distance of several feet. The feeder switching is done through this arrangement on the single pole principle, thereby saving space and making it possible to get twice the feeder capacity in the same switchboard space than would be the case if the usual double pole arrangement were used.

Each feeder is provided, in addition to its switch, with an ammeter, voltmeter and potential regulator. The potential regulators are of the type invented by Mr. L. B. Stillwell, and each consists of a regulating transformer, which is made by means of suitable switching devices to superpose or add more or less of its secondary potential to that of the feeder. The mechanical details for controlling these regulators are quite novel. Each regulator is hung under and supported by the upper floor of the switchboard and is provided with a switch dial controlled by a wheel on the front of the board within reach from the main station floor. By means of these switch dials the pressure of each feeder may be independently raised or lowered 18 per cent., making a total possible independent variation of 36 per cent.

By the use of an ingenious reversing switch the same transformer winding in the regulator is used for either raising or

lowering the pressure. To prevent any possibility of short circuiting between the regulator terminals when this reversing switch is thrown, the arm controlling it and the main regulator wheel, which both revolve around the same centre or shaft, are provided with a locking device which prevents both from being moved at the same time, or either from being moved when the other is not in a safe position. These regulators take up a space 11 inches in width, and each feeder is provided with a space one foot in width along the switchboards.

The regulators are hung by hooks from the "I" beams overhead in such a way that by raising them slightly by means of a portable windlass placed above, they may be disengaged and lowered to the basement floor. Before doing this it is necessary to disconnect them from the feeder cables and the regulator wheel shafts, all of which can be done in about five minutes. The regulator transformer switch dial and reversing switch are all self-contained and can be handled together. Within fifteen minutes' time any regulator can be cut out of service, removed from the board and another one put in its place.



PART OF SWITCHBOARD BASEMENT, SHOWING FEEDER REGULATORS SUSPENDED FROM FLOOR ABOVE, STATION "A."

During the two years in which these improved regulators have been in constant service it has not been found necessary, however, to cut out or remove a single one, as none have in any instance failed to do their work, and this without attention or repairs of any kind. With the maximum load on a feeder the loss in each regulator is less than three-fourths of 1 per cent. of the feeder load, and at smaller loads the loss is proportionately less.

The entire regulation of both feeders and generators is accomplished from the main floor of the engine room, the second floor of the switchboard being used only when feeder switches are to be thrown, and this is not necessary when the generators are being operated in multiple arc. A gallery is provided at a third level along the rear of the switchboard from which feeder fuses, lightning arresters and ammeters and voltmeters are accessible.

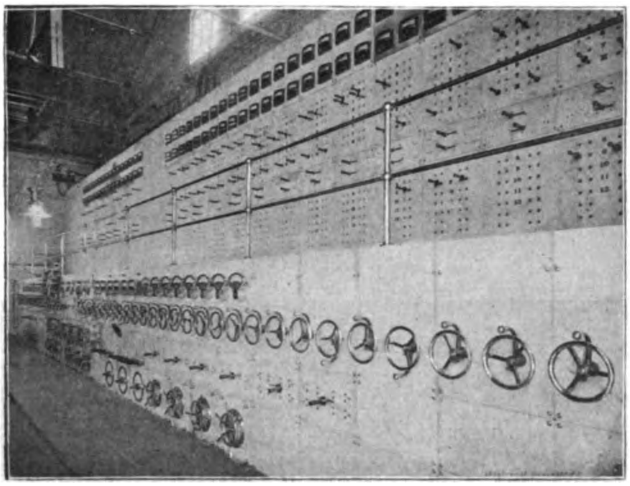
An unusual and very important feature of this switchboard is the fact that there are no parts of any kind carrying high potential current which can be reached or touched by an attendant from any part of the front of the switchboard. All high potential switches are placed in the rear of, or below, the switchboard, the operating handles only being placed on the front.

The feeder ammeters show the ampere load on each feeder, the feeder capacity being limited by the safe carrying capacity in amperes. The output of each generator is indicated by wattmeters, the load on each engine being dependent on the watt output of its generator, the capacity of which is not overtaxed with any load which the engine can pull. In addition to this indicating wattmeter, each generator is provided with a Thomson recording wattmeter, and by means of these recording wattmeters the entire station output is recorded. The voltmeters used in connection with each feeder are made to indicate the exact pressure at the feeder end or centre of distribution by means of pressure wires brought back to the station from such points. No feeder is operated nor regulation attempted without the use of pressure wires. All the indicating instruments were made by the Wagner Electric Manufacturing Company and are of their horizontal scale illuminated dial type, made extremely dead beat by the use of oil in which their mechanism moves and is retarded by suitable aluminum vanes.

This entire switchboard was constructed by the Wagner Electric Manufacturing Company after the designs of the lighting company's engineers. The greater part of the current used for incandescent lighting, constant potential arc lighting and alternating current motors is distributed through this switchboard

from this station. Tie lines of large capacity connect the switchboard of this station with that of station "B."

Opening from the basement under the switchboard and extending at a still lower level is the main cable terminal vault or tunnel, through which all cables are led from the underground conduits to the switchboard. This vault is 50 feet long, 9 ieet



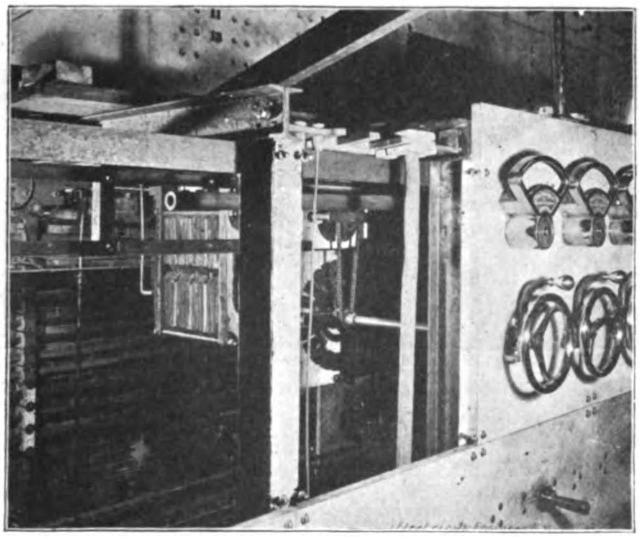
SWITCHBOARD IN STATION "A."

wide and 7½ feet high. Along its side are arranged adjustable cable racks, by which all cables are supported and carried to their proper position on other racks provided under the switchboard, which in turn carry them to their respective panels.

A consiaerable portion of the output of this station is still conveyed on overhead wires, but within three months all currenr will be led out through cables leading from this cable terminal vault.

STATION "B."

This station was originally built by the Municipal Electric Lighting and Power Company. Since the property was acquired by the Edison Illuminating Company, both the building and



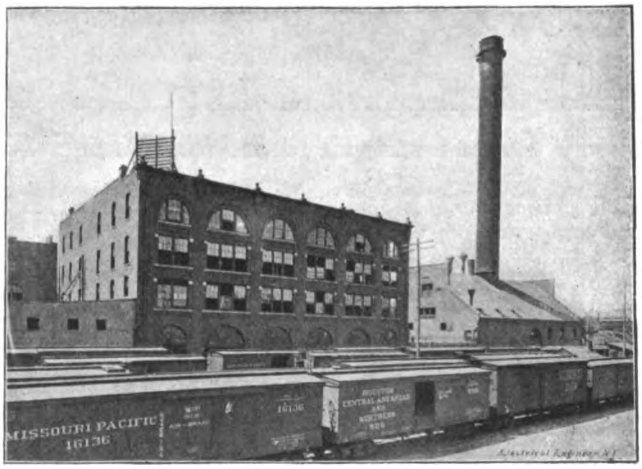
FEEDER REGULATOR, SHOWING METHOD OF HANGING FROM SWITCHBOARD, UPPER FLOOR.

steam apparatus have been almost entirely remodeled and a very large amount of new machinery has been installed. The main building, containing the engine room, is 105 feet long by 96 feet wide, and was originally constructed with four stories. Most of the second floor, which contained shafting and clutch pulleys, has now been removed, thereby increasing the height of the engine room to 28½ feet. Across the street from this building is another, 108 feet long by 57 feet wide, containing the boiler plant. The extreme height of this building is 60 feet. In this are placed twelve 350 h. p. Heine water tube boilers, built by the Heine Safety Boiler Company, of St. Louis. Seven more boilers of the same capacity can be installed in the additional space provided, and as yet left vacant. The floor of this boiler room is 23 feet below the street level, and connecting it with the engine room across the street is a large room excavated under the street, with floor at the same level as the boiler room proper. This room is 50 feet long by 50 feet wide, and in it are located the heaters and the main steam and exhaust pipe lines running from the boiler room to the basement of the engine room. Tne street above is supported by iron columns and "I" beams.

In the engine room are located one 1,500 h. p. cross compound Hamilton Corliss engine, directly connected to a 1,000 k.

CABLE TERMINAL VAULT, STATION "A."

w. alternating current generator, built by the General Electric Company; one 1,500 h. p. simple Hamilton Corliss engine direct connected to one 1,000 k. w. General Electric alternating current generator; one 750 h. p. simple Hamilton Corliss engine direct connected to one 500 k. w. 500-volt direct current General Electric generator; four 650 h. p. simple Hamilton Corliss engines, belted to line shafting on floor above, clutch pulleys on which operate by means of belts forty 60-light Wood arc machines on the third floor; two 100 k. w. 500-volt Fort Wayne bipolar generators; one 80 k. w. 500-volt General Electric multipolar generator, and one 100 k. w. 500-volt Eddy multipolar gen-



EXTERIOR OF STATION "B."

erator are also operated on the third floor in the same way by belts. Two 125 h. p. Westinghouse compound engines direct connected to two 100 k. w. 125-volt direct current General Electric generators used for exciters, are also located on the engine room floor.

Along one wall of the engine room, 18 feet from the floor, is the main switchboard, supported from the wall and partly hung from the girders overhead. On the third floor is located a switchboard used in connection with the arc light machines for series arc lighting circuits. The fourth floor is used for repair shops and storage.

ENGINES.

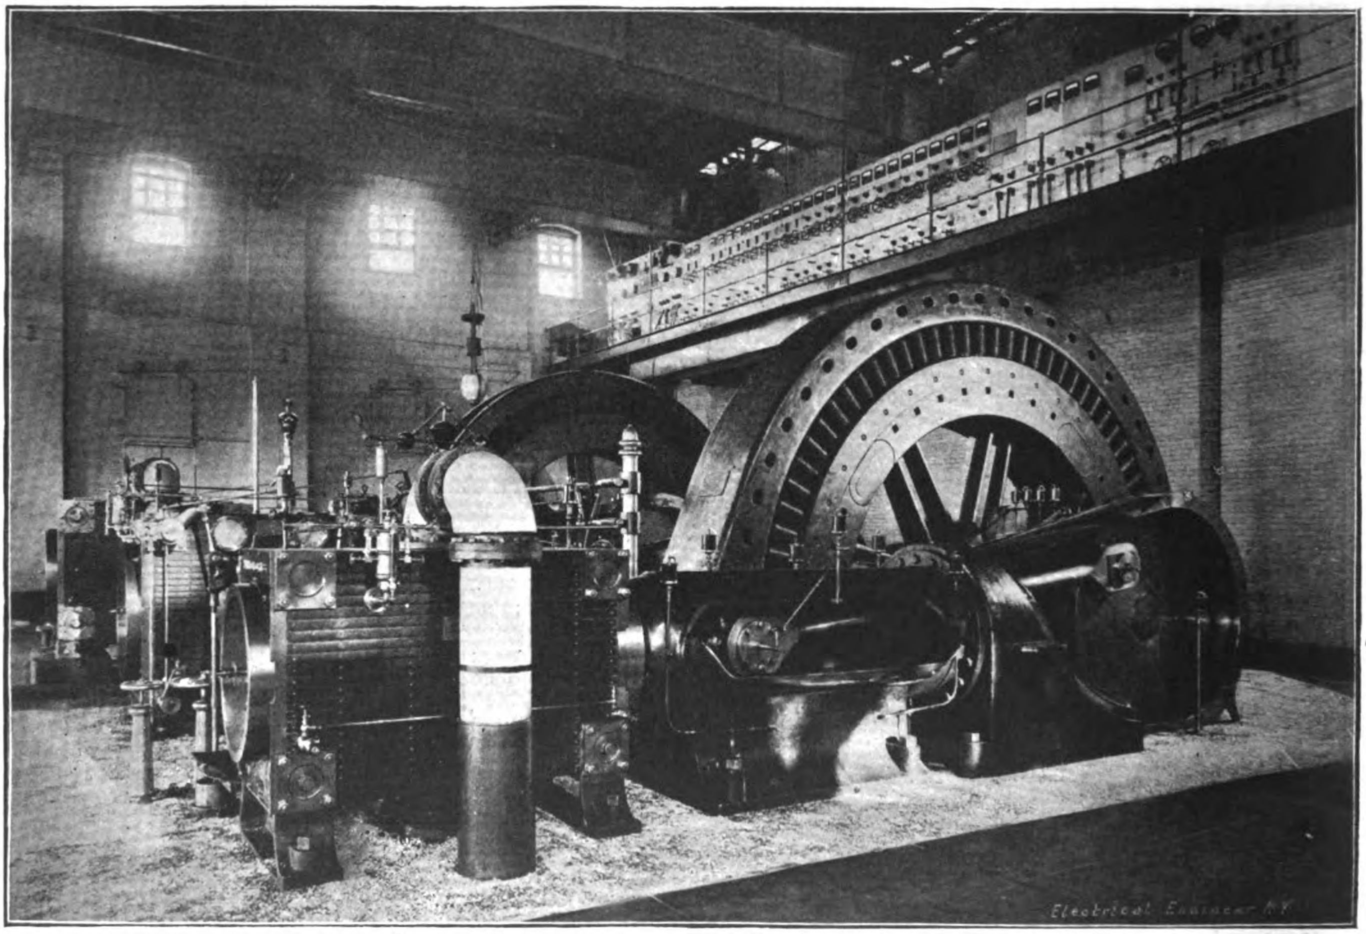
The engines in this station are all of the Hamilton Corliss type, built by the Hoover-Owens-Rentschler Company, of Hamilton, O., with the exception of the two 125 h. p. Westinghouse compound engines, used to drive the exciter dynamos. The two largest Corliss engines are of 1,500 h. p. nominal capacity, running at a speed of 90 revolutions per minute. They can, however, be made to develop 2,000 h. p. each when required. One of the engines is of the cross compound type, with cranks placed at 90 degrees. The other engine is of the simple Corliss type with single crank. This second engine is intended to carry the

STEAM PIPING.

All of the steam piping in this station is placed under the main floor in suitable basement passages between the engine foundations. A duplicate steam pipe system provides each engine with a double steam connection. This duplicate system consists of one 24-inch main steam pipe line and an 18-inch auxiliary line, either one of which may be withdrawn entirely from service for repairs or inspection. The entire steam system from boilers to engines is so designed that any section of pipe can be withdrawn from service or completely disconnected and taken out without interfering in any way with the operation of the plant.

BOILERS.

The boilers are of the standard water tube pattern, manufactured by the Heine Safety Boiler Company, of St. Louis, and are each of 350 h. p. They are placed in batteries of four boilers each, and are connected by steel flues, lined with fire brick, to a single steel smokestack. The furnaces are all arranged for hand



1,000 K. W. GENERAL ELECTRIC GENERATOR DIRECT CONNECTED TO 1,500 H. P. HAMILTON-CORLISS ENGINE, STATION "B."

variable portion of the ordinary station load, so that the compound engine and others of similar type to be added from time to time can usually be kept running at very nearly their rated capacity, as this type of engine when compounded is of lower economy at fractional loads than the simple form.

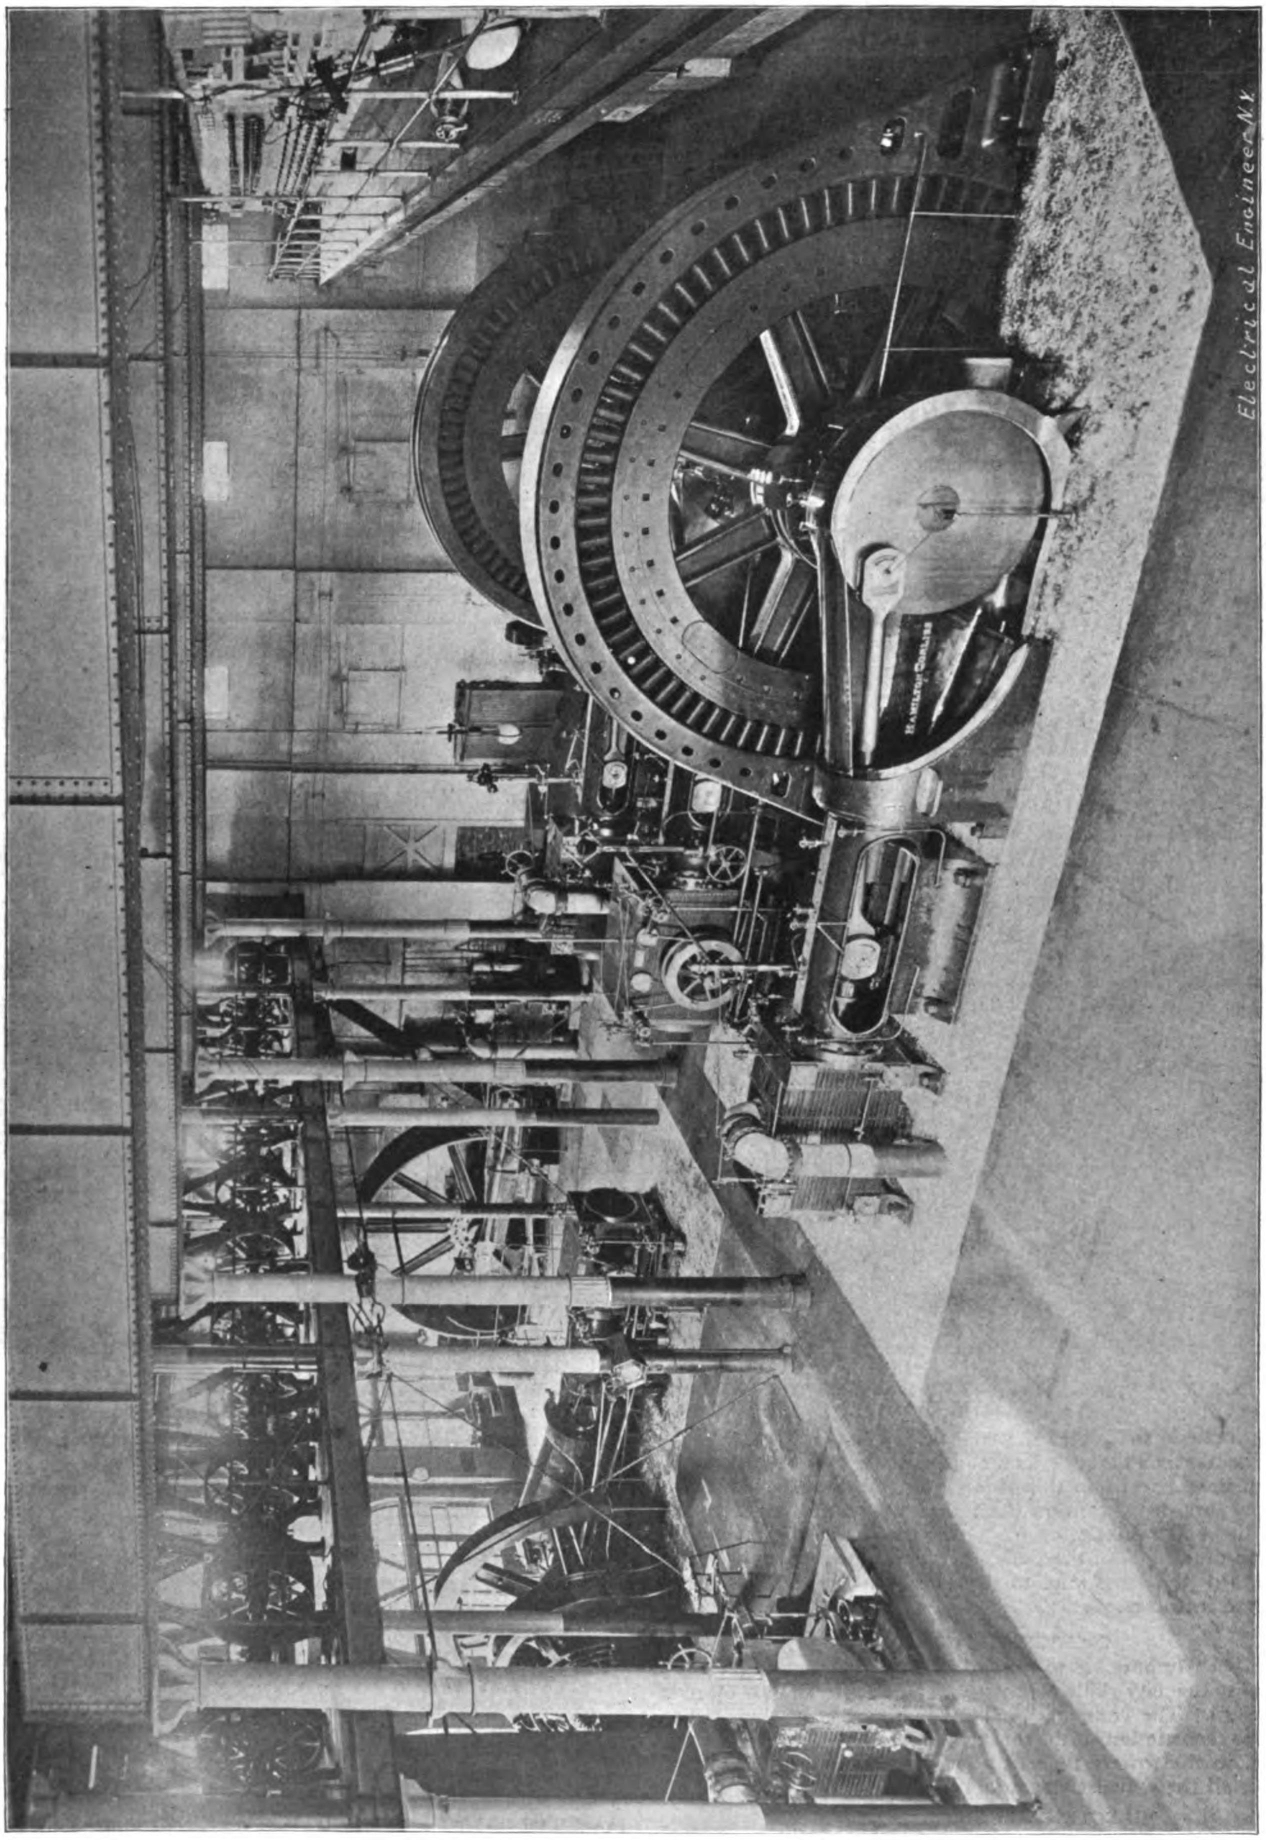
These engines are made extremely massive in all parts and are of the most recent design of heavy duty pattern. Each of these two engines, as before stated, drives a 1,000 k. w. alternating current generator, which will be more fully described further on. No other fly wheels are provided than the generator armatures, which are designed to perform the double duty of armature and fly wheel.

The 750 h. p. simple Corliss engine directly connected to a 500 k. w. 500-volt generator is of the same general design as the larger engines, and also runs at a speed of 90 revolutions per minute. The smaller engines, of 650 h. p. each, are of an older pattern and run at a speed of 60 revolutions per minute. All of these engines are at present operated non-condensing with 150 pounds initial pressure.

firing, experiments with several makes of mechanical stokers having shown that fully as economical results and greater reliability could be secured with the use of the old-fashioned method and usual form of flat grates.

SMOKESTACK.

The smokestack is of steel construction, lined with fire brick to a point 60 feet above the furnace grates. It is 13 feet in diameter and 204 feet high. The base is bolted to massive foundations, surrounded with concrete, covering it to a depth of about six feet. This smokestack successfully withstood the severe tornado which visited St. Louis about two years ago, although it was well inside of the edge of the path of the storm, and most of the buildings surrounding it were unroofed and more or less completely demolished. A massive brick smokestack at a street railway power house, less than a half mile distant, was lifted bodily from its foundations by this same storm and dropped, a shapeless pile of bricks, within 20 feet of its former location. The steel smokestack was originally located centrally in the



PORTION OF ENGINE ROOM, STATION "B," MISSOURI-EDISON ELECTRIC CO., ST. LOUIS, MO.

boiler house, and used in connection with 19 vertical boilers of the "porcupine" type; these were all replaced by the Heine boilers described, and arrangements are perfected to move the stack from its present location to a new position 20 feet to one side. This rather difficult operation is to be accomplished without shutting down the plant, and without depending on a system of guys to support the stack while being moved. The moving is to be done by the use of a great number of small steel rollers, rolling between "I" beams, and the base of the stack is to be weighted sufficiently to assure stability except in the strongest gale.

COAL HANDLING.

Above the boilers a large coal bin is built, occupying the entire width and length of the building. This bin is constructed of steel, supported on "I" beams and columns, the sides being sufficiently inclined to deliver the coal to a central position, from whence it descends through iron chutes to the boiler room floor. Coal can be delivered to this storage bin by means of mechanical conveyors, from cars on the railroad tracks located on one side of the boiler house, or from wagons in the alley running along the other side of the building. The ashes are elevated by conveyors of the same kind to overhead bins, whence they can be dumped into cars.

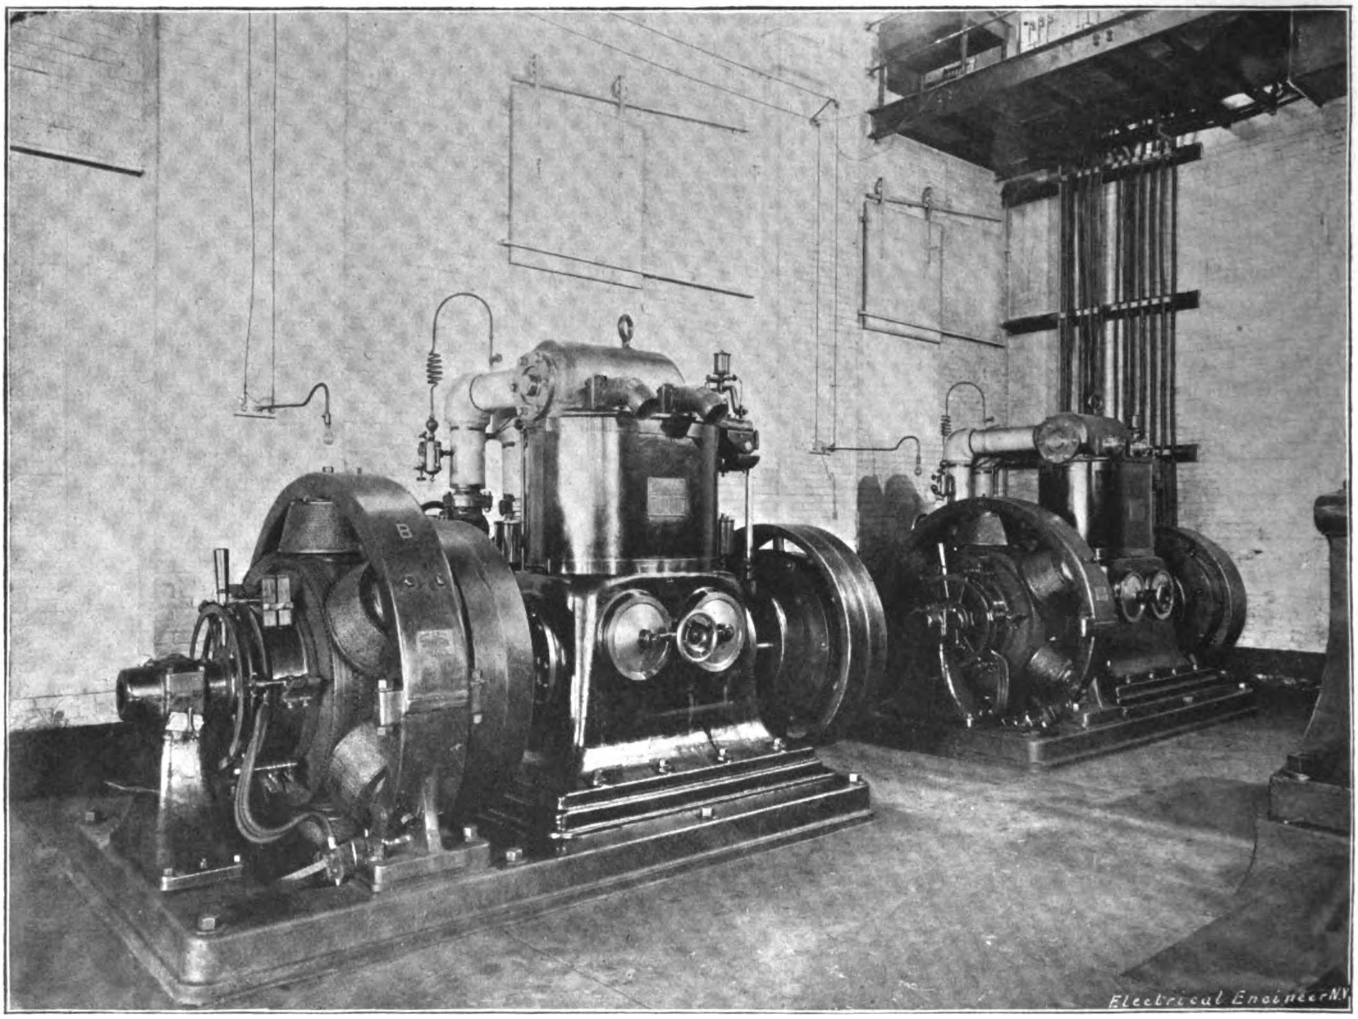
CONDENSING STEAM.

It has been impossible to obtain water for condensing in any location in the city which is otherwise suitable for an electric power plant. The company is about to install a cooling tower system in connection with surface condensers, capacity being provided in the towers to cool a sufficient volume of water to condense all the exhaust steam and maintain a vacuum.

ELECTRICAL GENERATORS.

The large alternating current generators in this station were built by the General Electric Company, as already stated. They were designed by the engineers of the General Electric Company after specifications, dimensions and sketches prepared by the writer. At the time of their construction they were the largest alternating current generators in dimensions ever built, and the largest in output, with the exception of the generators at Niagara Falls, which, however, run at a several times higher rate of speed. Their capacity, when operated single phase, is 1,000 k. w.

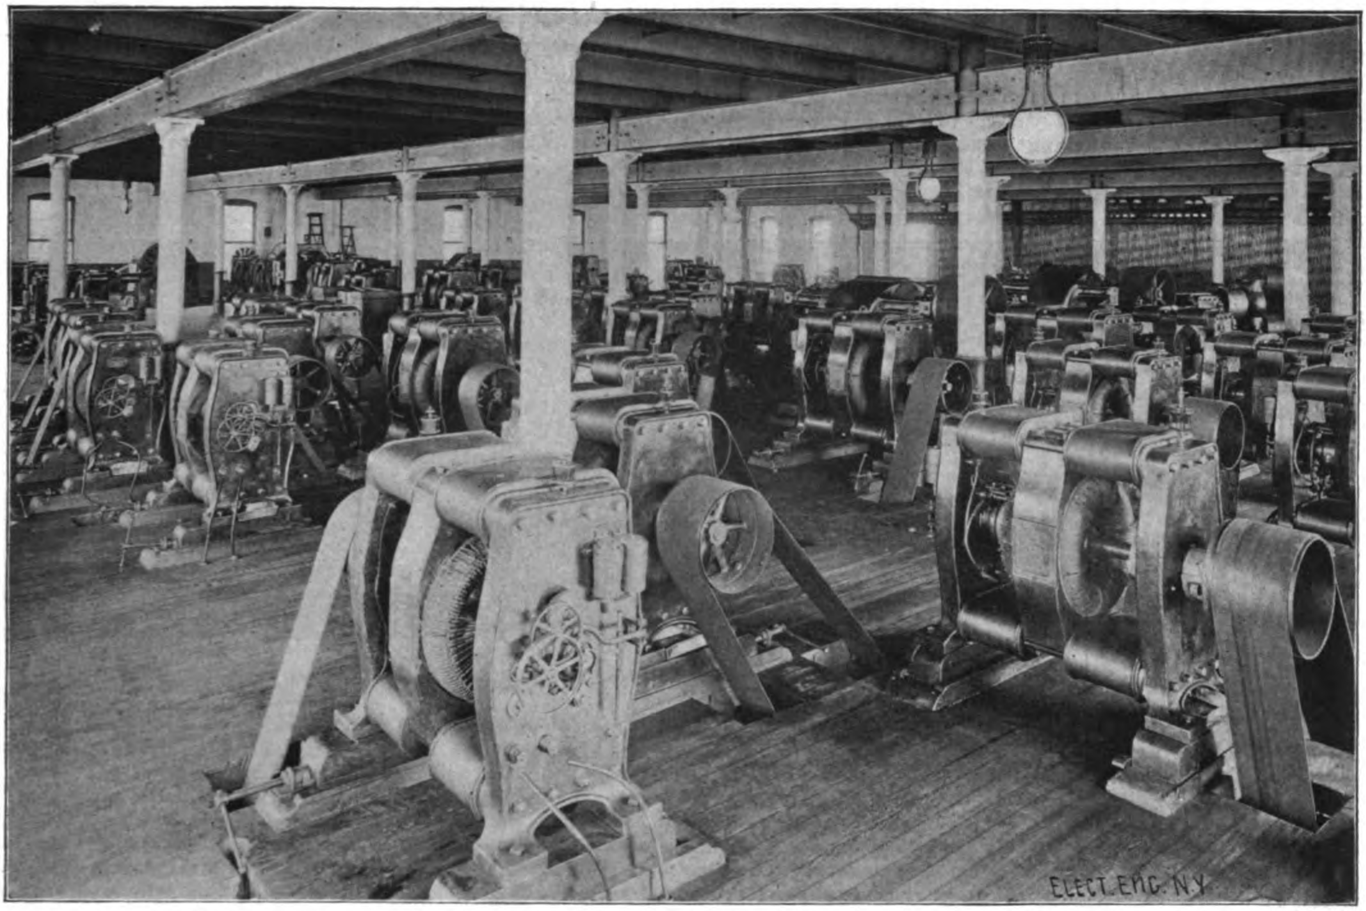
In addition to the single phase winding, another winding is provided in which current is generated differing in phase 90 degrees from the main winding. This quarter phase winding can be so connected as to enable the generators to be operated on the so-called monocyclic system, or on a three-wire single phase system. The generators are now operated at 1,200 volts on single phase only, as the company has adopted the single phase system as most suitable for its general distribution of current for light and power.



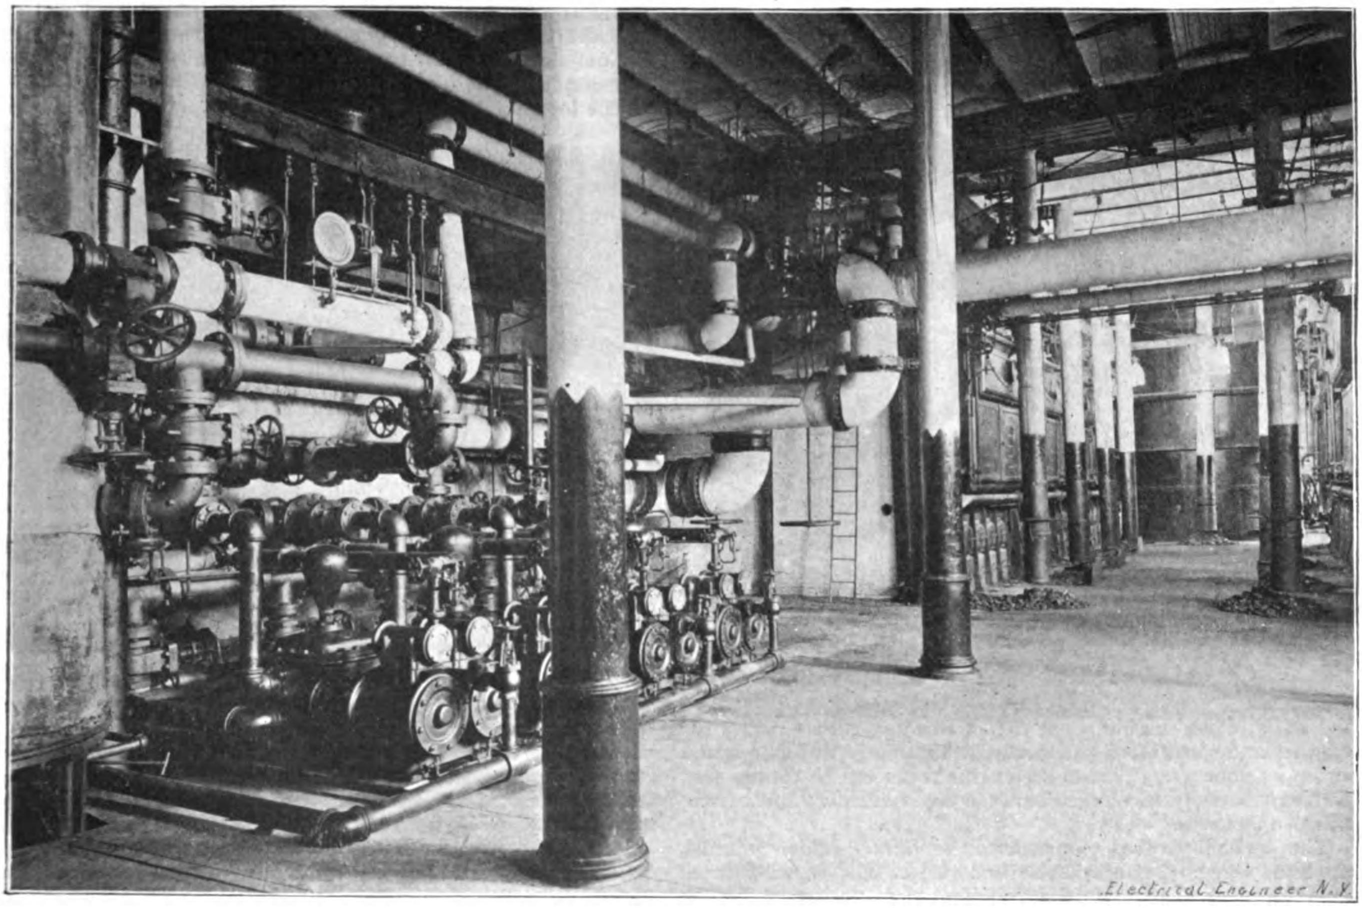
DUPLICATE EXCITER UNITS, STATION "B," MISSOURI-EDISON ELECTRIC CO., ST. LOUIS.

The armatures of these generators are constructed without polar projections, the copper bars forming the winding being embedded in slots as in the modern type of railway generator. They are 16 feet in diameter and have a weight of 100,000 pounds each. There are 80 field poles and the shaft is 22 inches in diameter, this enormous mass being provided to take the place of the usual fly wheel and to give the engines a very uniform angular velocity. A large margin for overloading was allowed in the design of these machines, and they are frequently made to carry for hours at a time a load of 1,200 k. w. They are so massive that even with this load the rise in temperature is almost inappreciable. The frequency adopted by the company for its entire system is 60 cycles, and the armatures revolve at 90 revolutions per minute.

Located near these generators are two 100 k. w. exciter generators, directly connected to compound engines. These exciter generators are of the usual General Electric type of multipolar



STATION "B."—VIEW OF THIRD FLOOR SHOWING WOOD SERIES ARC LIGHT DYNAMOS.

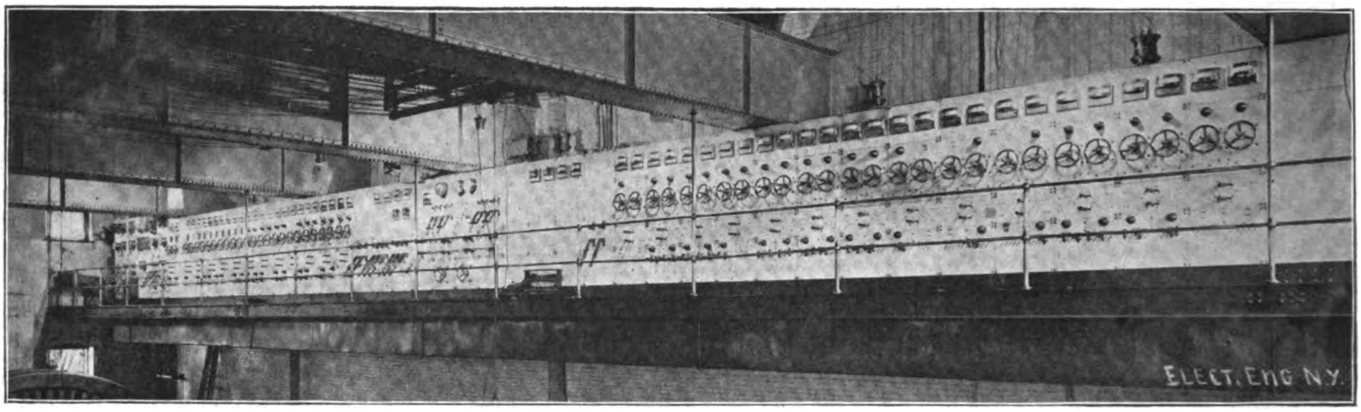


VIEW IN BOILER ROOM, STATION "B," MISSOURI-EDISON ELECTRIC CO.

direct current dynamos and deliver current at a pressure of 125 volts. Each one is capable of generating current for the fields of four 1,000 k. w. alternators.

The 500 k. w. 500-volt generator is of the most recent General Electric pattern. The total weight of this machine is 76,000 pounds, the armature weighing 32,000 pounds. The shaft is 18 inches in diameter.

On the third floor of this station, as already stated, are lo- exciters, and stretching away on either side are the feeder panels containing the necessary switching, regulating devices and instruments for each feeder. Beyond these feeder panels, at one end of the board, are located the switches, devices and instruments necessary for controlling all the 500-volt generators and feeders. Each alternating current feeder takes up a space on the switchboard panels one foot in width and six and one-half feet in height.

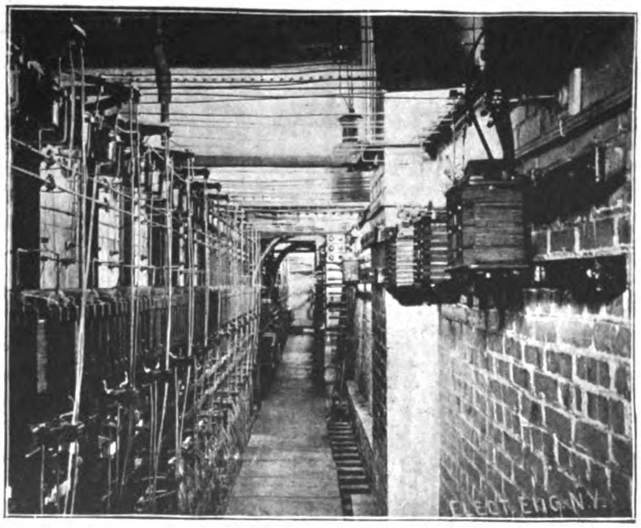


MAIN SWITCHBOARD, STATION "B," MISSOURI-EDISON ELECTRIC CO.

cated a large number of series arc light machines. These dynamos are of the well-known Wood type, manufactured by the Fort Wayne Electric Company, and are of 60 and 80 lights capacity. They have all given excellent service in the eight years during which they have been in daily operation, but the company's business has increased at a such a rate that some method of operating arc lamps on larger generating units was found imperative. The series arc lamps operated by these generators are, therefore, being rapidly replaced with alternating current lamps, operated on the general system from the large generators. The small arc light machines are, therefore, being gradually thrown out of service.

SWITCHBOARD.

As in station "A," the main switchboard is one of the most interesting features of this station, and is so located along one of



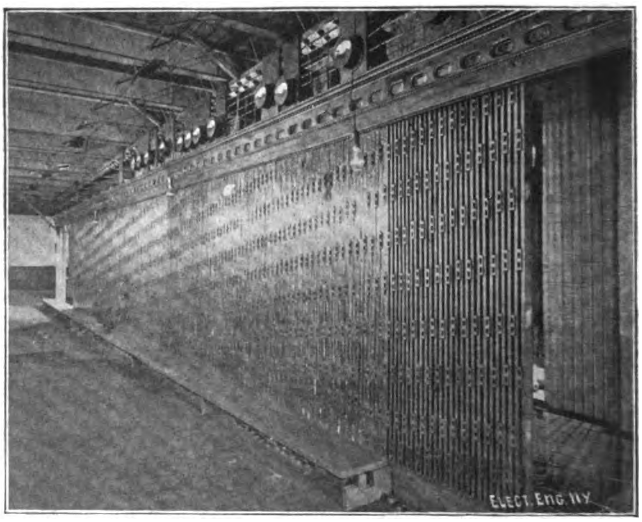
MAIN SWITCHBOARD, STATION "B," REAR VIEW.

the walls of the engine room that it forms a gallery above the engines and generators and occupies absolutely no floor space. From its floor every part of the engine room can be readily seen and signals easily exchanged between engine tenders and switchboard operatives.

The switchboard is constructed of white Italian marble, mounted in panels on an iron framework. The flooring is all made of black slate, as in the switchboard at station "A." The central part of the board is occupied by switches, regulating devices and instruments for the alternating current generators and

A large proportion of these feeders is used for operating alternating current arc lamps for city street lighting. The system devised for this purpose is one which has never been used before commercially, and will be described in detail further on. It necessitates the use of a 40 k. w. step-up transformer, a regulator, a switch and an ammeter for each feeder. The transformers used in connection with these feeders are of a regulating type, built by the Wagner Electric Manufacturing Company, and are hung from the "I" beams supporting the switchboard floor. The feeder regulators are controlled by means of hand wheels on the front of the switchboard and the current used is indicated by an ammeter of the standard horizontal scale illuminated dial type, manufactured by the Wagner Company. The switches and fuse cut-out devices are of special construction, designed to prevent any arcing of the high potential currents.

The location of the step-up transformers and the large amount

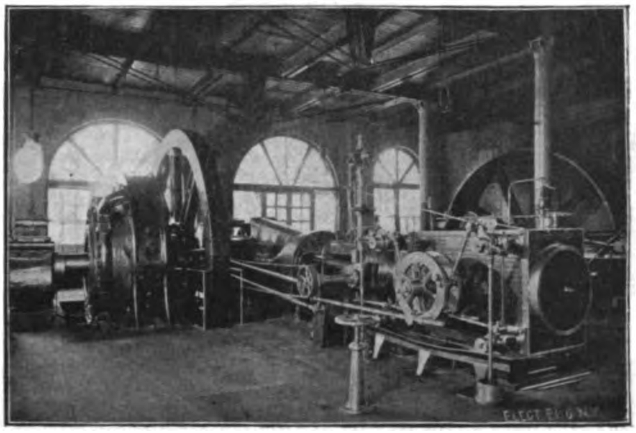


OLD SERIES ARC LIGHT SWITCHBOARD, STATION "B."

of energy transformed by them in a very limited space rendered it desirable to provide better means of ventilation than the natural air circulation afforded. For this purpose an air blast system was devised and constructed, by means of which a low pressure blast of air is directed through the spaces between the coils of each transformer. This is accomplished by a large air pipe two feet square, hung below the switchboard floor directly in front of the line of transformers. Openings are cut in this pipe opposite each transformer and air is supplied by a 72-inch Sturtevant blower, also hung under the switchboard floor against

the wall at one end. This blower is driven by a 15 h. p. single phase alternating current motor. The entire switchboard and all the devices used thereon was built by the Wagner Electric Manufacturing Company.

On the floor above there still remains the greater portion of the old series arc light switchboard, installed when the station was originally built. This is still used in connection with those series arc dynamos which remain in use.

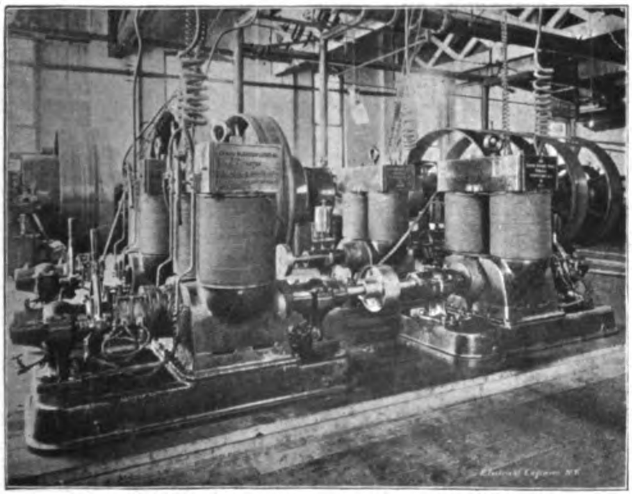


500 K. W., 500 VOLT GENERAL ELECTRIC POWER GENERATOR, AND 750 H. P. HAMILTON-CORLISS ENGINE, STATION "B."

The greater part of the current generated at this station, outside of that used for arc lighting, is delivered to station "A," 5,000 feet distant, through tie lines of large carrying capacity. This current is then distributed from station "A."

STATION "C."

This station was until recently operated by the St. Louis Electric Light and Power Company, the Missouri-Edison Electric Company taking control of it in February last. The arc light and alternating current machinery was at once removed and the station converted into a distributing point for a portion of the 500-volt power system. The equipment now consists of six 125 h. p. tubular boilers; two 300 h. p. Russell engines and three 150 h. p. Russell engines; two 80 k. w. Edison bipolar 250-volt generators, one 110 k. w. 500-volt multipolar generator, built by the Eddy Electric Manufacturing Company, and four 30 k. w. Edison bipolar 250-volt generators. All of the machinery in this station is used as a relay or reserve, in case of accident or repairs to machinery in the other stations.

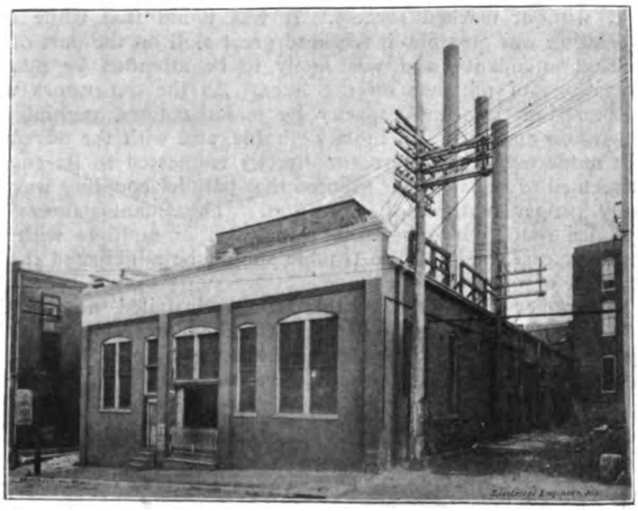


ROTARY EQUALIZERS FOR 500-250 VOLT, 3-WIRE POWER SYSTEM, STATION "C."

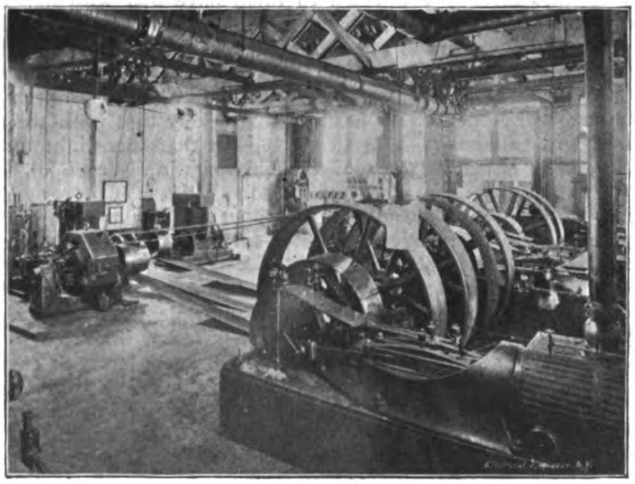
The St. Louis Electric Light and Power Company operated motors on both the 250-volt and 500-volt systems. The systems were, however, kept entirely separate. The two systems are now combined, and the 250-volt distribution carried out by the adoption of the Edison three-wire system applied to the 500-volt lines. The 250-volt generators are connected, two in series, with a middle connection to the neutral bus-bar, and can, therefore, be used for either 250-volt service or 500-volt service. The entire 250-volt system is usually operated by means of the 500-volt generators alone, two sets of rotary equalizers located at station "C" serving to balance the two sides of the 250-volt system very perfectly.

ROTARY EQUALIZERS.

Each set of rotary equalizers consists of two 30 k. w. Edison bipolar 250-volt generators with their armature shafts directly coupled together. They are connected to the switchboard and thence to the system in exactly the same manner as two generators on the three-wire system. To start them, one is used as a motor with the necessary starting resistance switched in series with the armature. In case the load becomes heavier on one side of the three-wire system than on the other the generator on the lightly loaded side becomes a motor and drives the other machine as a generator to supply the current for the difference in load. The equalization of pressure is accomplished so perfectly that the maximum difference of voltage on the two sides of the system at the switchboard is less than 1 per cent. To prevent fluctuations in the field strength of the equalizers the field of each equalizer is connected across the terminals of the opposite one. This equalizer system is not at all new, but seems to have rarely been a success where heretofore tried. This company, however, has never had the slightest trouble in any way with the equalizers or the manner in which they have accomplished their work, although they are old types of machines and designed for a different purpose.



EXTERIOR OF STATION "C."



PORTION OF ENGINE ROOM, STATION "C."

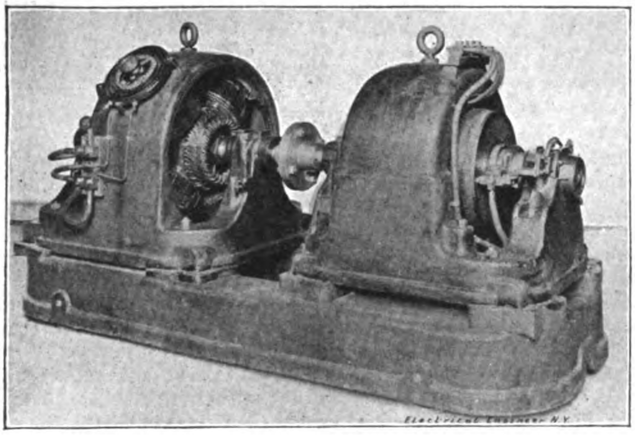
ALTERNATING CURRENT GENERATORS OPERATING IN MULTIPLE.

It has been the usual practice until quite recently in all American alternating current central stations, to operate the

generators independently, switching devices being provided to change feeders at will from one generator to another, so that with changes in load the grouping of the feeders on the generators could be changed as found necessary. In many European stations, more especially in Germany, alternating current generators have for years been operated in multiple arc. The advantages in multiple operation are too obvious to require discussion.

In this country numerous attempts were made to operate alternating current generators, of the earlier types, in multiple arc, without marked success. It was found that while such operation was possible, it required great skill on the part of the station attendants, and was likely to be attended by marked variations of pressure on the lines. As the generators were increased in size and capacity by manufacturers, multiple arc operation appeared still more desirable, and with the advent of the modern type of alternator directly connected to its engine, it seemed to be taken for granted that parallel coupling was the only proper method of operation. The manufacturers all claimed that their generators would run in multiple with the greatest ease, and that no trouble should be anticipated in this method of operation.

A number of water power plants were installed, notably that at Niagara, in which no difficulty was encountered in operating generators in this way, but success has not been marked where engines were used to drive the generators; in fact, almost all



15 K. W. ROTARY TRANSFORMER, SINGLE PHASE A. C. MOTOR AND D. C. GENERATOR.

attempts made to operate the generators in parallel when driven by engines directly connected to them have met with absolute failure.

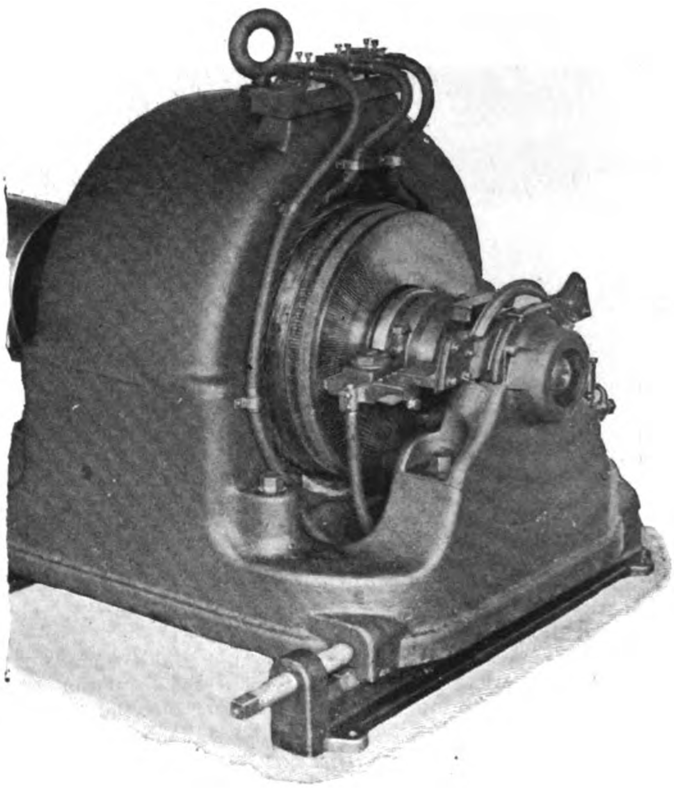
The manufacturers at once took the position that the engines were to blame and that the parallel coupling of alternators was no longer an electrical problem, but a matter of the proper regulation of the engine. It is more than likely that both the engines and generators were to blame, but that the slight modifications in either might render such operation successful. Be that as it may, the Missouri-Edison Electric Company has been able to overcome all difficulties in this connection and is operating its large direct connected alternating current generators regularly in multiple arc.

No difficulty whatever is experienced in operating a generator driven by a double crank engine in multiple with one driven by a single crank engine, although it is found desirable to so couple the generators that the crank of the single crank engine is in step with one of the cranks of the double crank engine.

The early efforts of the engineers of this company were not attended with any better success in this connection than that experienced at other stations, and it was only after a very thorough study of the subject and slight modifications of both engines and generators, that success was achieved.

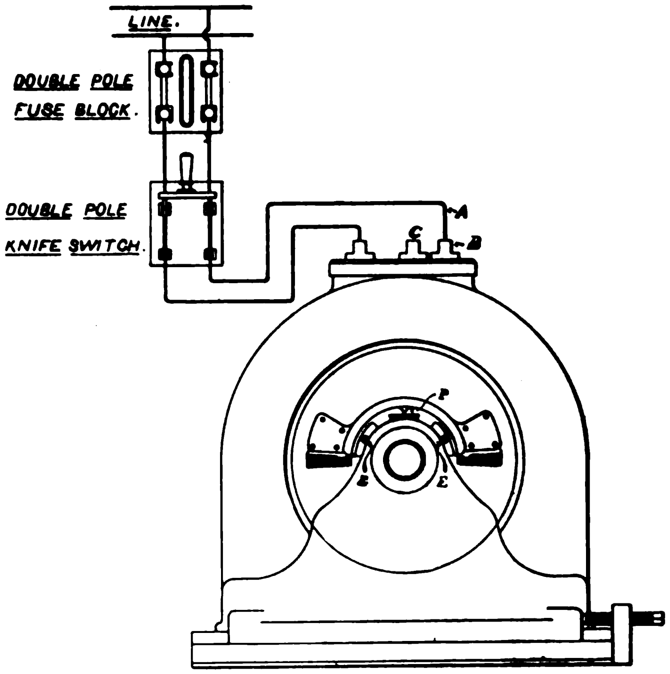
ALTERNATING CURRENT ARC LIGHTING.

It seems to be universally conceded that the enclosed long burning arc lamp is destined to replace all the old forms of arc lamps for commercial lighting. This type of lamp is now made for alternating currents, as well as for direct currents and about equally good results are now secured. The objectionable noise inherent in the alternating current arc, is, practically, entirely subdued in this form of lamp. It has been quite conclusively proved to the writer that the same amount of light for a given number of watts can be secured from a good, enclosed, alternating arc lamp, as from the same type of direct



15 H. P. WAGNER SINGLE PHASE A. C. MOTOR.

current lamp. While it is true that the alternating arc itself is less efficient than the direct current arc, the large percentage of energy wasted in the resistance which must be placed in series with the direct current arc, can almost all be utilized in the alternating current arc. The increased efficiency of resist-



15 H. P. WAGNER SINGLE PHASE A. C. MOTOR—DIAGRAM OF CONNECTIONS.

ance devices attained in the alternating current lamp thus fully compensates for the lower efficiency of the arc itself.

This company is now very rapidly replacing its direct current series arc lamps with the enclosed long burning alternating

MAP OF UNDERGROUND CONDUITS AND CONDUCTORS, MISSOURI-EDISON ELECTRIC CO., ST. LOUIS, MO.

arcs, those at present in use being manufactured by the General Electric Company.

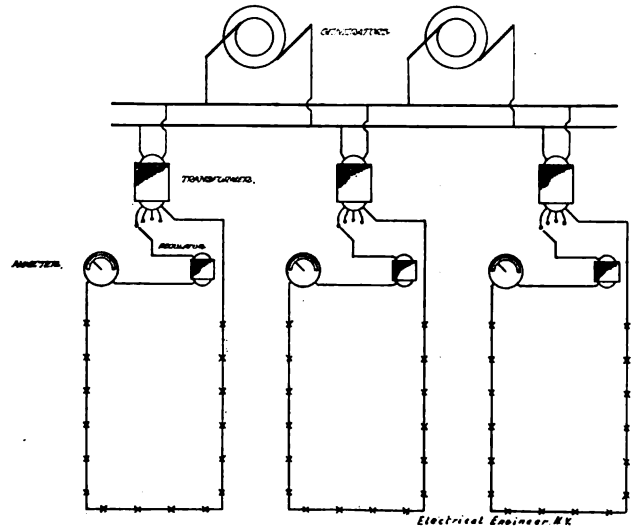
The company long ago appreciated the great advantage to be secured in the economy of operation, and in the saving in investment for relay or spare machinery, by furnishing current for all purposes from one type of generator. This could be readily accomplished with the exception of arc lamps for street lighting over very large districts, and for the operation of motors. The engineers of the company, therefore, devoted their attention largely to these two classes of service and the development of devices and methods by which they could be furnished from the general alternating current system. The results desired have been achieved in the most satisfactory manner.

A system for operating arc lamps in series by alternating current was devised and perfected by the writer, and after a few months' trial with an experimental circuit, it was found perfectly feasible to operate the existing series arc lamp circuits, with the same lamps slightly remodeled, from a step-up transformer for each circuit connected to the general alternating current supply system.

These step-up transformers were designed so that they could be readily regulated to furnish current for from one to eighty arc lamps in series. The system was finally adopted and the company now has 2,300 of these arc lamps in regular operation in this way. The circuits are each provided at the station with the regulating step-up transformer referred to, having a maximum capacity of 4,000 volts and ten amperes, and the feeders to these transformers are treated on the switchboard the same as the feeders for incandescent lighting. The location and disposition of the transformers and regulating devices on the switchboard, have all been described above in connection

with the switchboard at Station "B." It is not unusual for one alternating current generator to carry 2,000 of these lamps.

The lighting is satisfactory to the city and the lamps give better service than when before operated on direct current. There has been a very marked saving in fuel and attendance, and the indicated horse power per arc lamp is considerably less than with the direct current lamps. There is no other station in



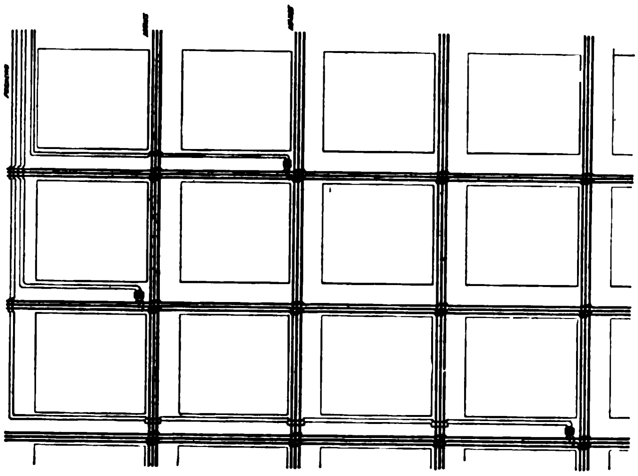
ALTERNATING CURRENT ARC LIGHTING SYSTEM OF DISTRIBUTION.

existence where arc lighting is done in this way, and the system stands as a very pronounced and most successful example of the flexibility and adaptability of the alternating current.

ALTERNATING CURRENT MOTORS.

For several years this company has been experimenting with different forms of motors suitable for operation on the alternating current system. The supposed impossibility of successfully operating motors on this system was one of the chief arguments against its use which were brought forward in the early days of central station practice. Within the last few years the use of current for power has increased very rapidly in the large cities, and the demand for a good alternating current motor became imperative.

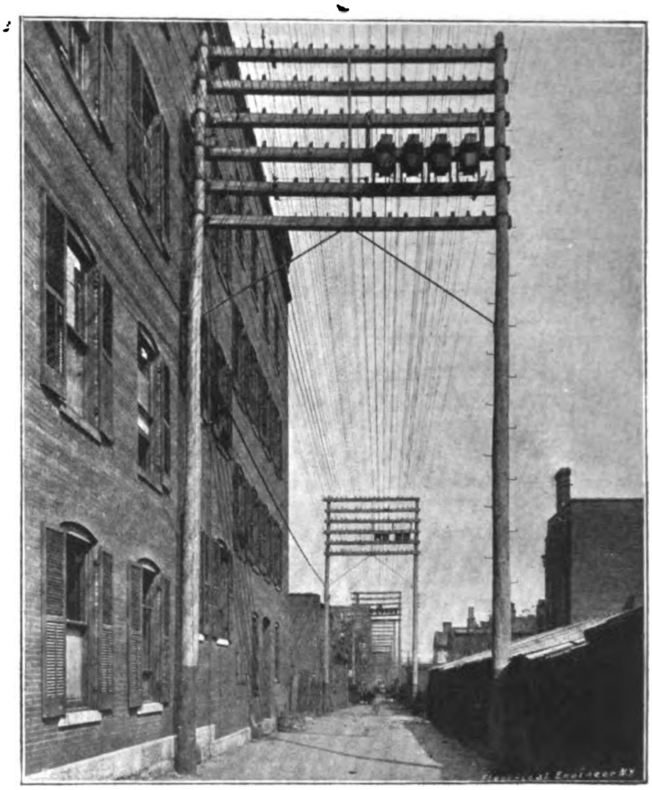
Motors for operation on the two-phase and three-phase alternating current systems have been so perfected that they are



GENERAL SYSTEM OF DISTRIBUTION.—HIGH POTENTIAL FEEDERS AND 3-WIRE LOW POTENTIAL MAINS.

equal in almost every point to direct current motors, and even superior in many ways. The complication, however, of the two-phase and three-phase systems when adopted for general distribution where lighting is the most important factor, and the impossibility of securing as good regulation as with the single-phase system, were so apparent to this company, and were such serious objections to the use of either of these two systems, that it was determined to make every possible effort to secure a good single-phase motor. This they have succeeded in doing, and the single-phase alternating current motors now manufactured by the Wagner Electric Manufacturing Company are being used very extensively on the company's circuits. It is the intention within the next six months to replace the entire 250 volt power service, comprising over 1,000 horse power in motors, by alternating current. Where the alternating current motors have been put in they have given better satisfaction to the customers than the old direct current motors. They require less care in starting, less attention while running, and slightly exceed the direct current motors in efficiency. The current is sold for them entirely on a meter basis.

In some cases for special uses, direct current is desired, and where it is necessary to supply such demand, the company installs a motor generator of the capacity required. The motor generator consists of a single-phase alternating current motor directly coupled to a direct current generator. The potential of the direct current generator can be controlled at will by a field rheostat, and the regulation of the service is therefore entirely under the control of the customer. Apparatus of this



AN EXAMPLE OF POLE LINE CONSTRUCTION.

kind has been purchased from the Wagner Electric Manufacturing Company, and is giving perfect satisfaction.

TERRITORY COVERED BY COMPANY'S LINES.

The company's distributing lines cover the greater portion of the city, and supply service to a district about ten miles long and six miles wide, not including several suburban districts located at a greater distance. The distributing mains run along over five hundred miles of streets. The greater portion of this system is overhead and carried by pole lines, although the company is now engaged in placing its wires underground at a very rapid rate.

Under existing ordinances, all wires must be placed under ground in the most congested portion of the city, comprising a little less than two square miles. In this district the company has its mains under about 30 miles of streets. By comparison with other cities, it will be seen that this company supplies a greater territory probably than that at present attempted by any company elsewhere.

SYSTEM OF DISTRIBUTION.

The general distribution for light and power done by this company, is accomplished by means of an alternating current single-phase system. A complete system of feeders and mains

is used throughout. In a large portion of the city, both feeders and mains are operated at 1,100 volts pressure, carried directly to the customer's premises, where transformers are located to change the potential to 110 volts. In the more thickly settled districts, however, the distribution is accomplished almost entirely at low pressure on the Edison three wire system at 220 volts. In the underground distribution, high potential is used only on the feeders, the entire system of mains being designed

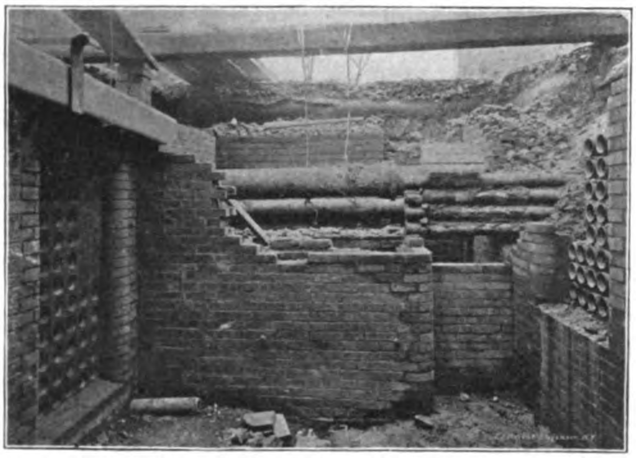
EDISON TUBING LAID ON DUCTS.

for 220 volts three wire. This portion of the system is almost identical in detail with that used by the large stations operating the Edison three-wire direct current system. The usual form of Edison tubing consisting of iron pipe enclosing three copper rods separated by an insulating compound, is used very extensively. The system of mains forms a complete network passing along and connecting almost every street.

At street intersections, junction boxes are located in manholes. These junction boxes contain fuses which will disconnect from the system any block in which a serious defect or

UNDERGROUND CONDUIT CONSTRUCTION.—A FEEDER LINE.

short circuit occurs in the cables or tubing. Any block may also be cut out at will by the same means. Located at the various centres of distribution or feeder terminals, are transformers each of 110 k. w. capacity. These transformers are placed in large manholes, and their primary coils are connected directly to the ends of the feeders, one feeder supplying current to only one transformer, and each feeder being entirely independent of any other. No primary fuses or cut-outs are used in connection with these transformers, as the feeder fuse at the station serves every purpose. The three wire secondaries of each transformer are brought to terminals in a junction box, also located in the manhole. From the bus-bars in the same junction box, pressure wires are run back to the station for each feeder. It will be seen that in this way the transformer is practically made a part of the feeder, and that its drop in potential with load can be considered as part of the feeder drop. The most perfect regulation can be secured and maintained by this system, and

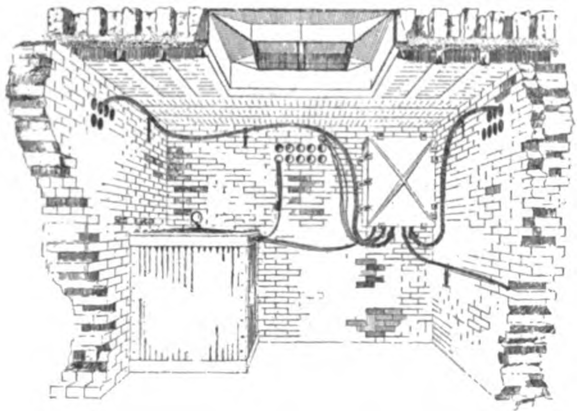


UNDERGROUND CONDUIT CONSTRUCTION SHOWING PORTION OF MANHOLE AND CEMENT-LINED PIPE CONDUIT.

transformers of a higher average efficiency can be designed than any heretofore used.

The average load on the company's lines is about 20 per cent. of the maximum load, and the transformers are designed for the highest efficiency at this load. The transformers used by the company for this purpose are made by the Wagner Electric Manufacturing Company and the Westinghouse Electric and Manufacturing Company, each having supplied a number of these transformers built to the specifications and dimensions of the company's engineers. The specifications call for an efficiency of slightly under 98 per cent. at one-quarter load.

This system of distribution is believed to be the most perfect of any alternating current system in use, and is installed here for the first time. The economy of distribution is very much higher than anything heretofore attained with alternating current, and slightly exceeds that of the best Edison direct



MANHOLE WITH TRANSFORMER AND JUNCTION BOX.

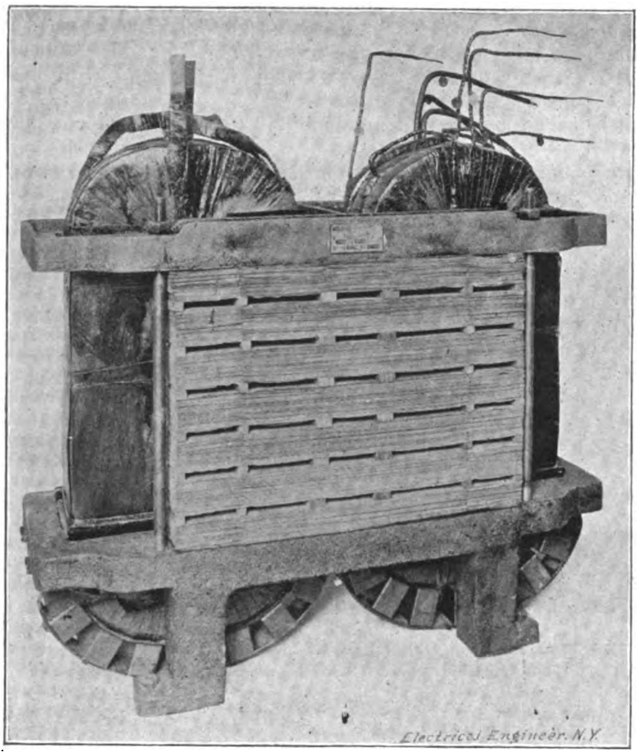
current stations. With an average load of 20 per cent. the distribution efficiency of the entire underground system from the generators to the lamps is 95 per cent.

UNDERGROUND CONDUITS AND CABLES.

For many years the company has appreciated the advantages of having its wires underground in the most thickly settled portions of the city, but owing to numerous complications which arose in the attempts to secure proper legislation for the control of underground conduits, the company until

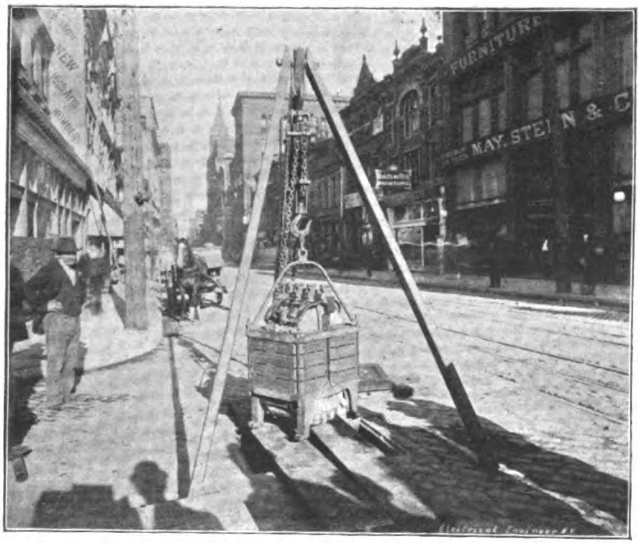
less than two years ago was compelled to place most of its wires overhead.

In April, 1897, the company began conduit construction on a large scale, and having investigated thoroughly the different types of conduit and ducts, contracted with the National Con-



80 ARC LIGHT, 40 K. W., CONSTANT CURRENT TRANSFORMER, FOR TRANSFORMING FROM CONSTANT POTENTIAL TO CONSTANT CURRENT.

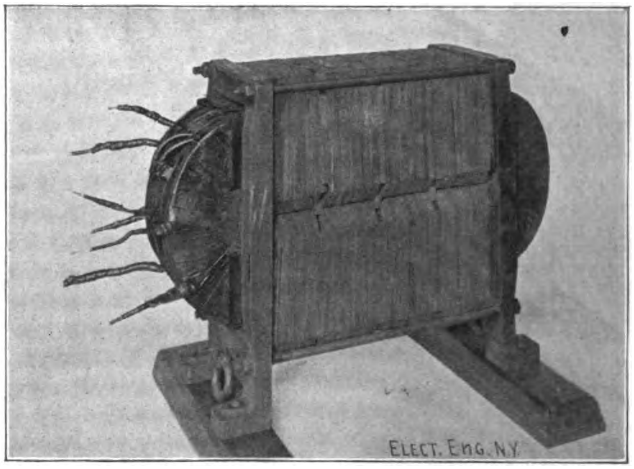
duit Company of St. Louis, to lay about 800,000 feet of cement lined iron pipe. The installation and construction of this conduit system is now completed. The system consists, on most streets, of a multiple duct conduit for both feeders and mains. At every street intersection, a manhole is located, the sizes of these manholes varying from five feet square to eight feet square, the minimum depth being six feet six inches in the clear. With but few exceptions, the manhole covers are all



100 K. W. TRANSFORMER READY TO LOWER INTO MANHOLE.

provided with large slots for ventilation, and nearly every manhole is well drained to the sewer system.

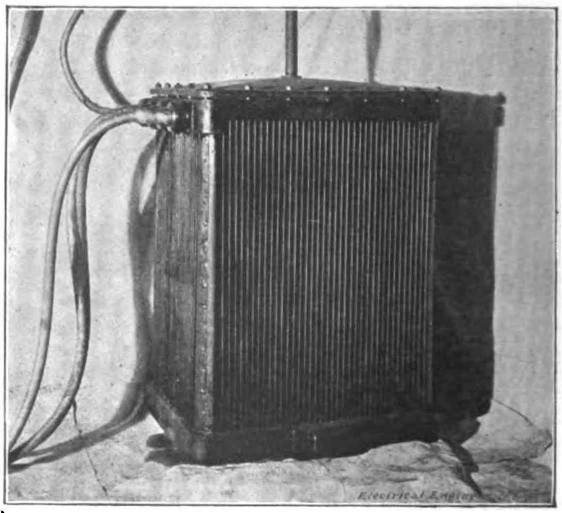
At intervals of from 50 to 75 feet, along every street, are located service boxes 3 feet square, and of the necessary depth to admit the top layer or row of ducts in the conduit. These service boxes are covered by watertight iron covers and provide means for connection with buildings along every street at every alternate building line, so that each customer can be independently connected to the distribution cables. The upper ducts which open into these service boxes are utilized for cables for distributing mains, the lower ducts being reserved for feeders and tie mains. On many streets the usual form of Edison three-wire tubing is also used in connection with the main sys-



80-ARC LIGHT TRANSFORMER.

tem, and on the streets in the retail shop districts the Edison tubing is laid on each side of the street to avoid frequent crossings of the entire width of the street for service connections.

The size of the conductors used for feeders is 150,000 circular mils, and all feeder cables consist of two of these conductors insulated with rubber compound and enclosed in one lead sheath surrounding both wires. This type of cable is usually called "twin conductor." The twin conductor feeder cable was purchased from the Safety Insulated Wire and Cable Company of New York City. The sizes of the conductors used for distributing mains, vary from 100,000 circular mils to 300,000 circular mils. Almost all of these main cables are rubber insulated and were furnished by the General Electric Company. The three conductors are made into one cable which is also covered with lead. The service cables are all of the three-wire type, and are most of them insulated with paper, and lead covered. For 500 volt direct current power service, twin cables are used for mains, a portion being covered with paper insulation and some with rubber insulation, and all being lead covered. They were

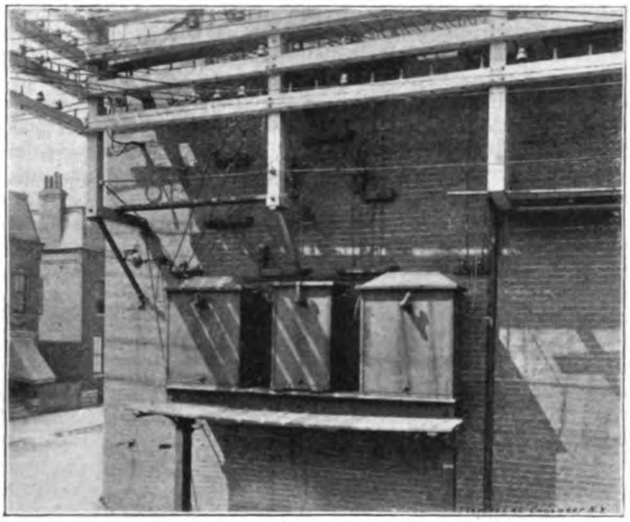


110 K. W. WAGNER TRANSFORMER FOR USE IN MANHOLES.

furnished by the General Electric Company, the National Conduit and Cable Company, and the Safety Insulated Wire and Cable Company.

The junction boxes used in manholes are of the four-way

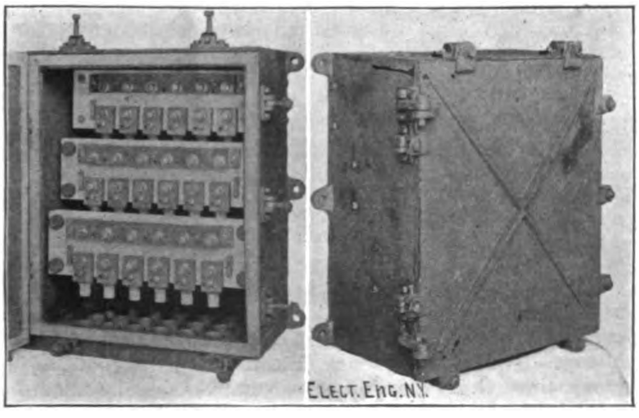
and six-way three-wire type. They consist of large cast-iron boxes with hinged and bolted covers, which can be so closed as to be watertight. Inside are mounted three heavy bus-bars on thick marble slabs. On these marble slabs are also placed, at a suitable distance from the bus-bars, terminals for each cable. Between these cable terminals and the bus-bars, copper fuses are inserted. The boxes are so designed as to secure the greatest distance possible with the limited space between the opposite poles, and to provide for the ready removal of any cable without interfering with any other or danger from short circuiting. These junction boxes are a modification of the Tailleur box used by some of the Edison direct current companies, and were manufactured by the Wagner Electric Manufacturing Company.



STEP-UP TRANSFORMER ON WALL.

TRANSFORMERS.

All of the lighting done by this company, is, of course, on the transformer system, and the total capacity of the transformers employed is somewhat in excess of the station generating capacity and somewhat less than the total number of lamps connected. Over a large portion of the system the usual form of transformer is used. These are of the most modern standard types manufactured by the Wagner Electric Manufacturing Company, the Westinghouse Electric and Manufacturing Company, and the General Electric Company. For long distance transmission to suburban districts, step-up transformers are used at the station to raise the potential to 5,000 volts. Similar transformers are used at the further terminals of these lines, reducing to 1,100 volts again. The step-up transformers most generally employed are of 100 k. w. capacity, placed in large iron boxes, in which the transformers are surrounded by oil for better cooling and insulation.



THREE-WIRE JUNCTION BOX USED IN MANHOLES.—OPEN AND CLOSED.

In addition to these transformers are the large transformers used for underground distribution, which have already been mentioned. The Westinghouse Electric and Manufacturing Company have designed and constructed eight of these special transformers for the Missouri Edison Electric Company. These are uniformly of a capacity of 110 k. w. To economize space in the manholes where it is necessary to locate these transformers, it was desirable to make them as compact and as small in dimensions as possible. By a most careful consideration of design it was found possible to get them within dimensions as follows: Height, 42 inches; width, 34 inches; depth, 26 inches. To provide the greatest possible radiating surface, the sides of the boxes are deeply corrugated, most of them being made of a special form of corrugated sheet iron firmly attached to castings at top and bottom. The specifications for these transformers limited the iron loss to 250 watts, and the copper loss to 3,200 watts. Both of these items are somewhat lower in the transformers as built. At average loads the rise in temperature of these transformers will be exceedingly small, and at full capacity will be well within safe limits during the comparatively short periods per day, when they will be called upon for full supply.

LIGHTING AND POWER WORK OF THE COMPANY.

Inventive genius is constantly devising new applications for electricity, and the number of uses to which the current is now put in the various industries in a large city is almost legion.

The fact that this company employs alternating current in the largest portion of its distributing system seems to have had no effect to limit the number of applications, and practically all of the work is being accomplished in St. Louis with alternating current that is done in other large cities with direct current. In addition to the alternating current system the company has, as already described, a comprehensive system of 500 volts direct current distribution.

The advantages of the alternating current for long distance transmission of current for distribution have been utilized in reaching the principal residence and suburban districts. It is safe to say, therefore, that no other lighting company in existence can boast of as many residence lights. The total number of residence lamps connected to the company's supply lines is at present 75,000.

The commercial lighting of the company includes the lighting of stores, offices, factories and hotels. This portion of the company's business now aggregates about 93,000 lamps.

In addition to these two classes of lighting there are 8,350 incandescent lamps used in lighting city buildings and portions of streets and alleys. This lighting is done under a contract with the city and covers a period of ten years ending January 1, 1900.

The arc lighting furnished by the company is principally included in the two classes, commercial lighting and city lighting. For commercial lighting there are now about 2,100 lamps in use. Under contract with the city the company also furnishes about 2,500 arc lamps of 2,000 c. p. each for street lighting. This contract was for a period of ten years and expires on January 1, 1900.

For power work an ever increasing amount of current is being demanded, the greatest growth of the company's business during the last year having been in this department. The number of uses to which electric power is applied is only limited by the number of applications found for motive power of all classes in the mechanic arts. Many of these are familiar to everyone, and the field is too great to attempt to describe in detail. The company is at present able to furnish either alternating current, 250 volt direct current or 500 volt direct current for power use.

One of the latest and most important applications of electric power is that of elevator service, both freight and passenger. The electric motor lends itself admirably to this class of work, and it is predicted by many that hydraulic and steam elevators will soon be a thing of the past. The company is prepared to operate either of the latter kinds of elevators, however, by the use of motors applied indirectly to the elevator mechanism.

For hydraulic elevators the motors are required to drive power pumps which displace the steam pumps ordinarily used. In one instance the company is operating a steam elevator by means of compressed air supplied by a compressor driven by an alternating current single-phase motor. This installation is unique and interesting, and promises to open up a field for service, which could not otherwise be secured, owing to the great cost of changing the steam apparatus for the direct connected electric.

At this time of year the most prominent application of electricity is for driving ventilating fans and small desk and ceiling fans. The number of these fans on the company's circuits reaches up into the thousands and is not included in the figure of total horse power of motors operated by the company. The small fans are so easily moved about and connected to any lamp socket that it is impossible for the company to keep track of them, or any record of their number.

STATION MANAGEMENT, USE OF METERS, ETC.

The large extent and many ramifications of the company's business renders its separation into many departments most necessary. Under the General Superintendent of the company are six Superintendents of Operating Departments, each department having its own special duties and being held responsible for such by the General Superintendent.

Each station has its corps of operatives under the direction of several foremen or chiefs of divisions. Over these are placed a Superintendent of Steam Department, and a Superintendent of Electrical Apparatus. The overhead system of lines forms an important department, separate from the department of underground lines.

In addition to the different department divisions, each station forms practically a department by itself, and all accounts are kept separate for each station, and each station's record for economy of operation is accessible at any time. One very important department has in charge the testing, repairing and maintenance of all meters and instruments.

Practically the entire output of the company is paid for on a meter basis. With but few exceptions, each customer has a meter where the wires enter his premises, and bills are rendered in accordance with the meter record. The entire amount of current delivered is recorded in this way, but the actual output of current from each station is also recorded by wattmeters, through which the current from each generator must pass. On the record of these station output meters is based the determinations of cost per unit of each item entering into the company's operating expense.

The meters used are those manufactured by the Westinghouse Electric and Manufacturing Company and the General Electric Company. Most of the meters used for alternating current are of the induction type and have been shown to be most accurate and durable in continuous service. The company has on its lines over 10,000 of these meters, and the entire maintenance and care of this number requires the time of only four young men.

The difference between the records of the station output meters and the meters showing delivery of current to the customers' premises represents the losses in distribution and in the meters themselves, due to their occasional failure to register the entire amount of current passing, when this is extremely small. The average losses shown by this difference are quite appreciable in amount, but appear exceptionally small when compared with those recorded by other companies.

THE COMPANY'S OFFICERS—CONCLUSION.

It is impossible in the scope of this article to go into the many smaller details of the construction of the plants and distributing systems of the company and its methods of managing and operating its business. From what has been said, however, some idea can be gained of the unparalleled extent of the distribution system, of the many problems which have been solved by the company's engineers, and of the new and original systems and appliances developed.

The success of the company is largely due to the excellent personnel of the organization. The officers of the company have had large experience in the management of large interests, and the Directors are most representative of the city's large commercial institutions.

The officers are: President, S. M. Dodd; Vice-President, James Campbell; Secretary, Sherman B. Pike; Treasurer, J. G. Kelly; General Superintendent, Herbert A. Wagner. Board of Directors: S. M. Dodd, James Campbell, J. C. Van Blarcom, James W. Bell, Thomas H. West, Edwards Whitaker and R. C. Kerens.

Electrical Apparatus for Spain.

Even Spain shares in the general rush for American electrical machinery. The Westinghouse Electric and Manufacturing Company, through its London representatives, has installed one of its 135 k. w. single-phase separately excited alternators, belted to a Westinghouse engine, for the Malaga Electricity Company, of Malaga, Spain. The decay of Spain's power might be traced largely to the absence of engineering ability. She cannot build her own machinery, and in most cases she is unable to operate it when it is built.

THE SELECTMEN OF MIDDLETOWN, CONN., have granted permission to the Middletown Street Railway Co. to extend its tracks from Pameacha Park to Crystal Lake Park, a distance of four miles. Work will be begun at once.

Storage Battery of the Chicago Edison Co.

IN the admirable lecture delivered by Mr. Samuel Insull before the electrical engineering students of Purdue University at Lafayette, Ind., that gentleman dwelt at considerable length on the function and value of the storage battery in electric central stations. That he has the courage of his convictions is evident from the fact that the Chicago Edison Company has just completed the installation of what is probably the largest storage battery plant in the world, situated in the basement of the Edison building on Adams street, Chicago.

The causes which led up to the installation of this battery are worth dwelling upon as paralleling the experience of many another company. The business growth of the Chicago Edison Company had been such during the past year that the down-town winter maximum increased from 36,000 amperes in 1896 to 44,000 in 1897, and, assuming the continuance of the present growth, the winter maximum of 1898 on the down-town system will be in the neighborhood of 55,000 amperes. In fact, a point had been reached where new investment in machinery or battery had to be made. The peak of the load occurs in winter time at about 4:45 p. m., and is about 12,000 amperes in height, with an average duration varying from three-fourths to one and one-quarter hours.

The conditions of a battery installation from the point of investment were very favorable, since the current is carried from the Harrison street station to 139 Adams street, the site of the original plant, over a trunk line 3,500 feet in length, and then distributed. The old Adams street site was, therefore, a very favorable point for a battery installation, since a large trunk line investment was avoided. Moreover, the centre of load of the system has been gradually moving farther away from 139 Adams street, so that for good regulation at time of maximum load in winter, with feeders varying from 800 feet to 3,000 feet in length, either a booster system or a large outlay in copper had to be considered. The battery filled the conditions, being designed to discharge on two voltages, 125 volts to accommodate short feeders, and 140 volts for certain long feeders, although it is equipped with a third-end cell switch, so that still another voltage of discharge can be obtained should the future necessitate it.

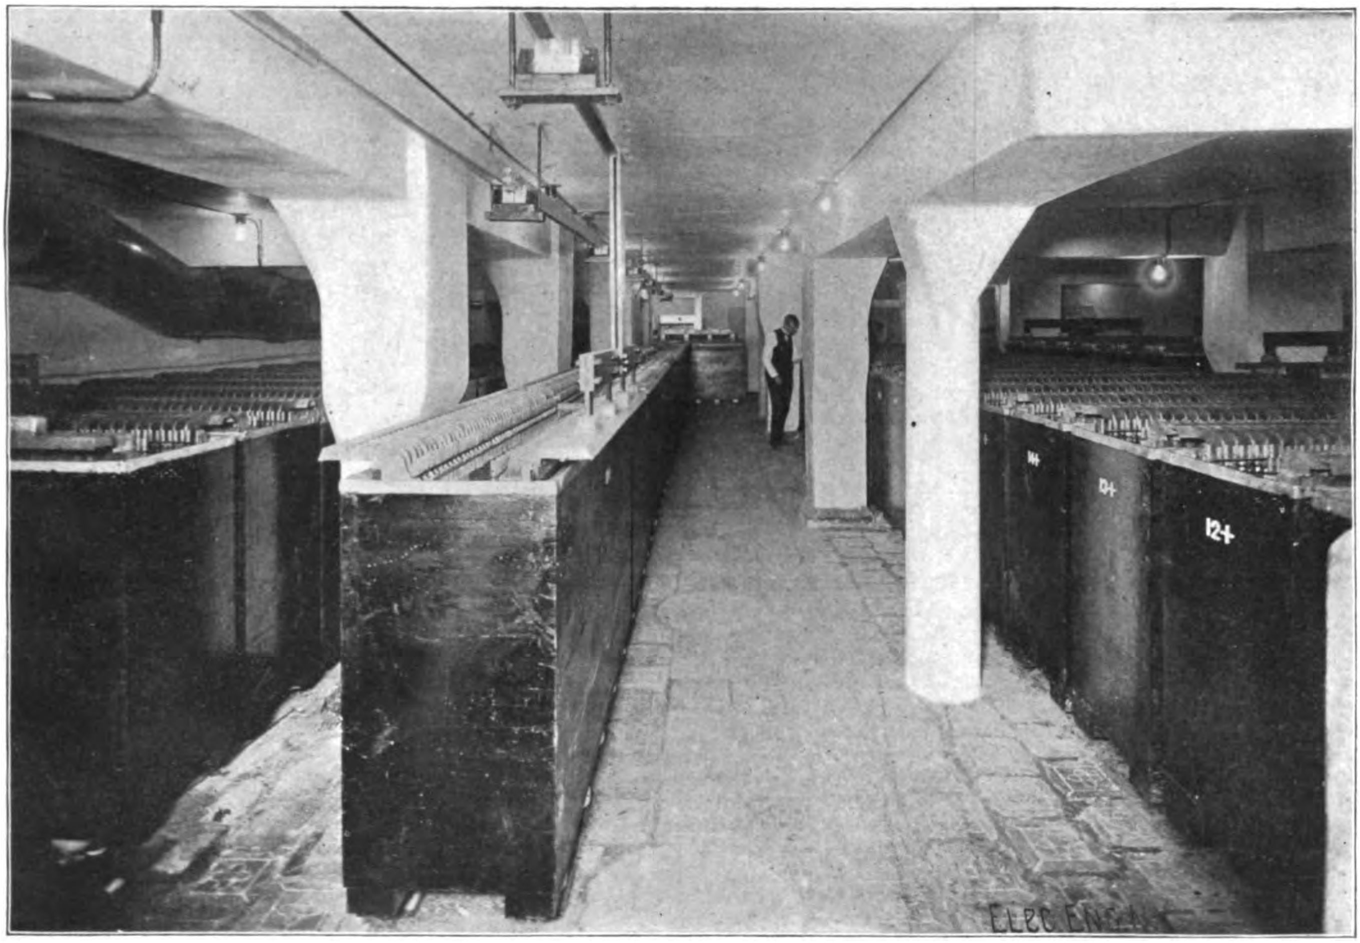
LOCATION.

The battery is located in the basement of the office building of the company at 139 Adams street. Precautions were taken to see if the footings of the columns supporting the floors above would be sufficient to sustain the weight of a duplicate installation in the future. New footings were necessary and the building was temporarily shored up. The question of permanency in every detail was the first consideration, as the size of the installation and the limited area and head room made alterations in the future out of the question.

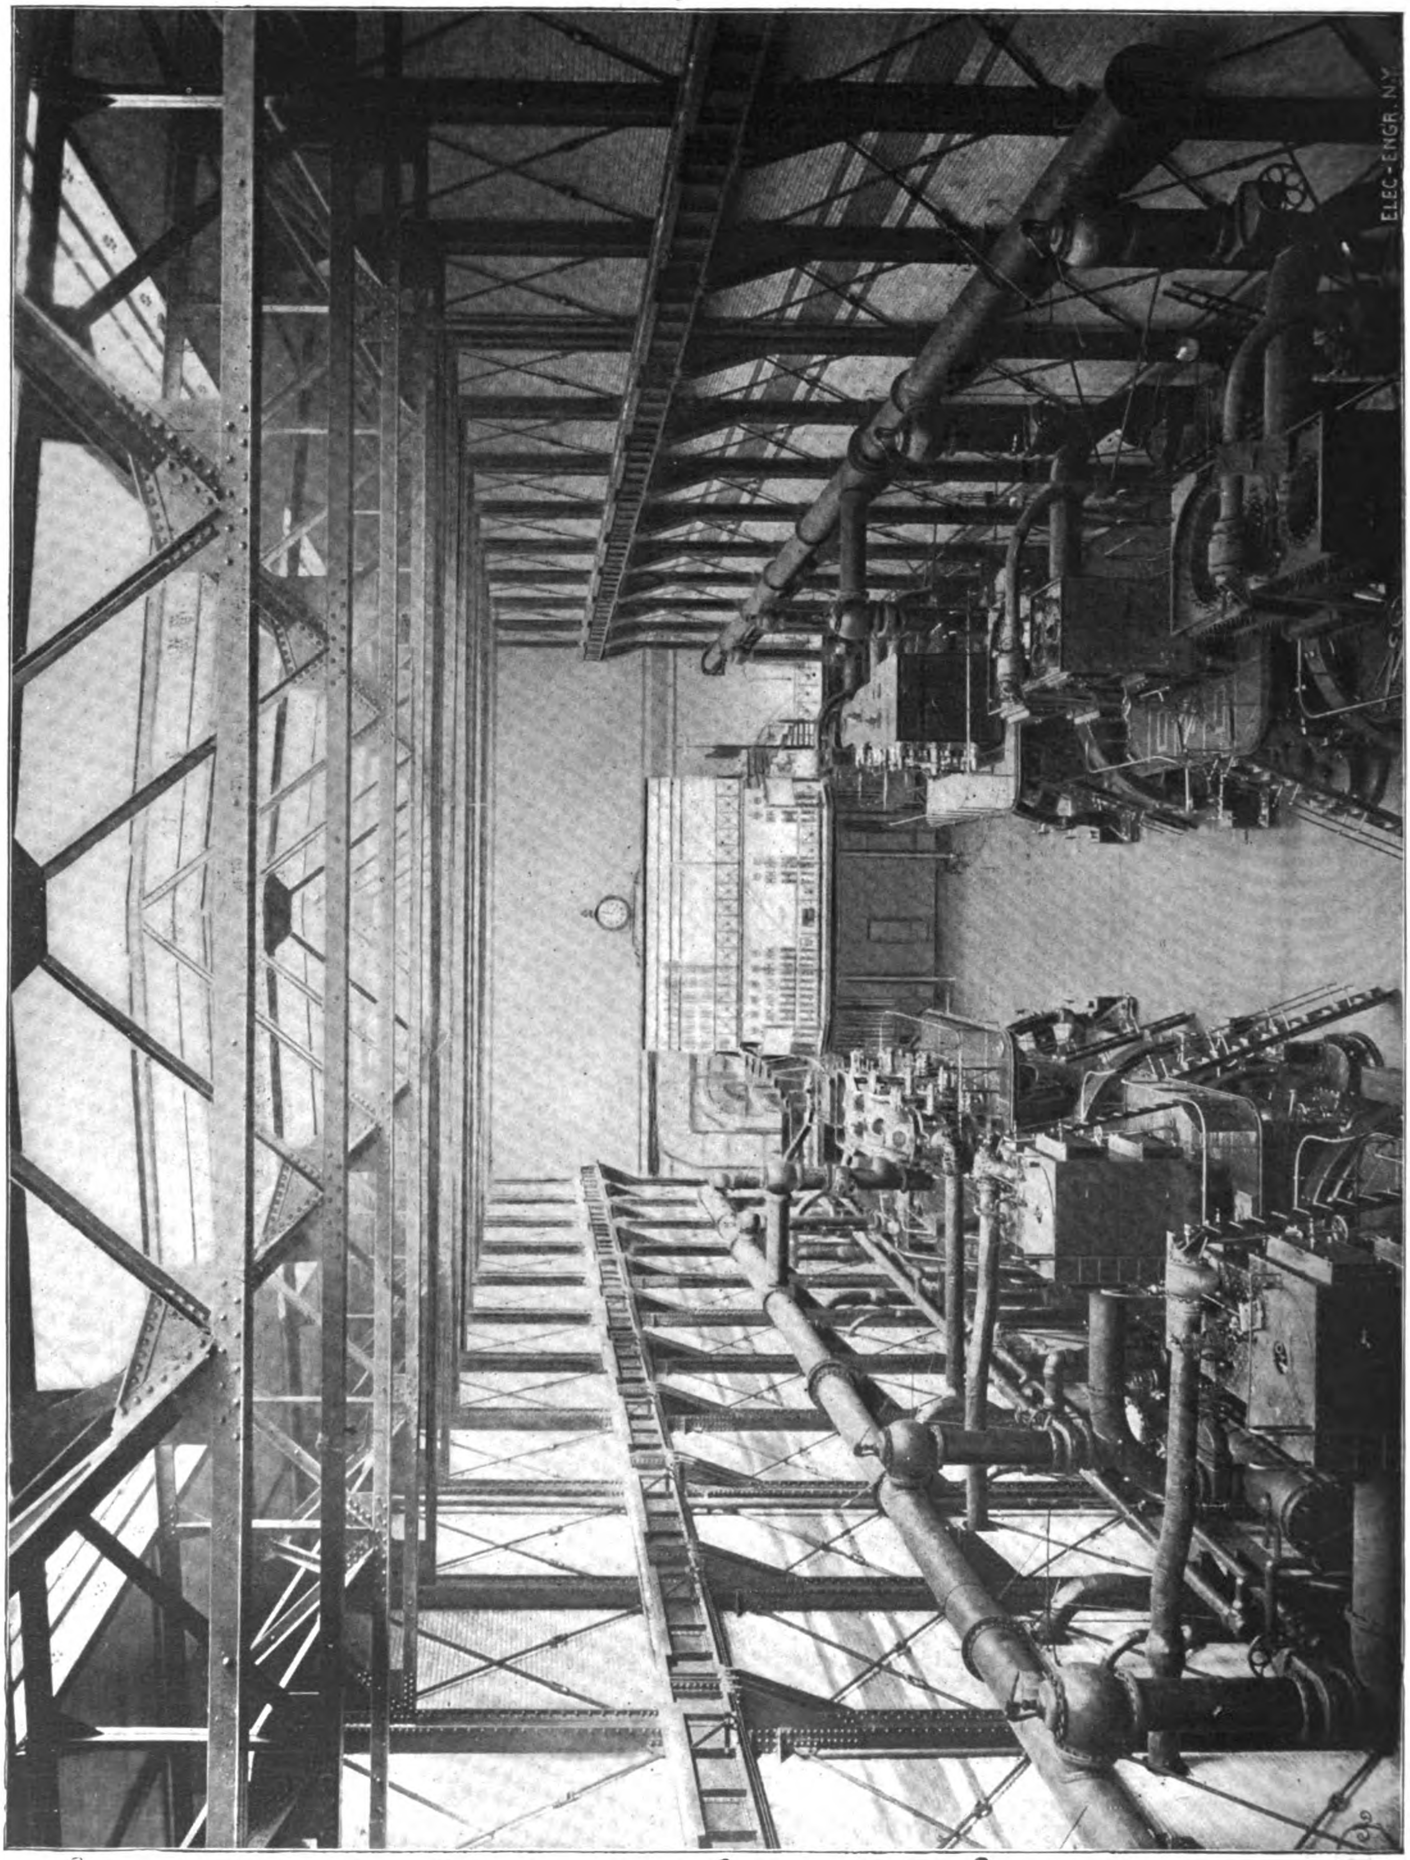
The matter of sub-drainage, surface drainage, supports for the cells against ceiling, as the building is not piled and on soft ground, the floor and protection of the columns and iron beams supporting the upper floors of the building and the ventilation were most carefully considered. A sub-drainage system of 3-inch tile pipes laid in concrete was installed and surface drainage lead pipe laid in sand draining several lead-lined sumpts, and both draining into a large sumpt at the extreme south end of the room, which is emptied by a lead-lined centrifugal pump and discharged to the sewer. To prevent settling, five 4-inch I-beams were laid crosswise under the cells, the space between being filled with concrete. Over this a few courses of tarred felt were laid.

The floor is of vitrified shale tile, 10x10x2 inches, laid in a mixture of 70 per cent. of asphalt to 30 per cent. of coal tar. The bottom of the columns is encased in lead. The columns were carefully cleaned, then treated with a galvanic varnish and afterwards encased in wire lathing and covered with an alkaline cement plaster and then covered with a coating of anti-acid paint. All of the walls and ceilings are treated with the same plaster and are rendered impervious to acid fumes.

For ventilation, two ducts on opposite sides were run the en-



STORAGE BATTERY PLANT OF CHICAGO EDISON COMPANY.

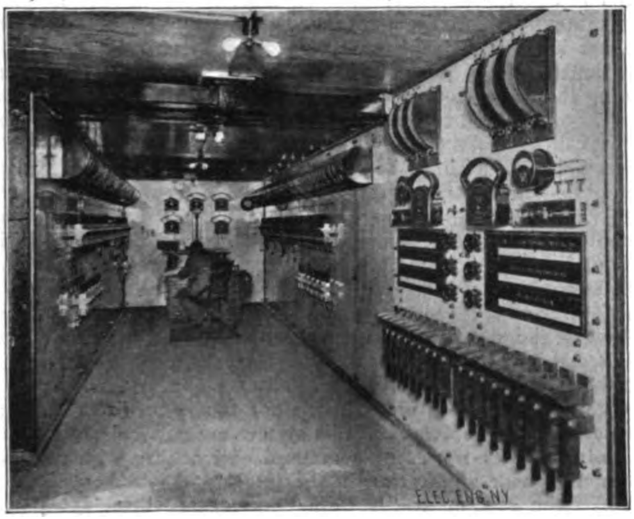


INTERIOR OF THE DYNAMO AND ENGINE ROOM SEEN FROM ELECTRIC CRANE HARRISON STREET STATION, CHICAGO EDISON CO.
(See Elec. Engr. of Jan. 25, 1895.)

tire length of the room, one for blowing in fresh air, the other for exhausting. This affords several cross currents of air and effectually removes the gases, which are conveyed to the roof and blown to the outer air.

THE BATTERY.

The battery has a capacity of 22,400 ampere hours at an eight-hour rate, and will be able to discharge 11,000 amperes for about one and one-quarter hours. It consists of 166 chloride accumulator cells (60 of which are end cells), 83 on each side of the three-wire system. This large number of end cells is required to meet the wide conditions of pressure. The battery is called upon to deliver 140 volts on each side at the end of discharge, and in case of an emergency to deliver current at a maximum of 120 volts on each side when fully charged. Each cell contains 87



SWITCHING ROOM, CHICAGO EDISON CO.'S STORAGE BATTERY PLANT.

plates (known as type "H"), whose dimensions are 15½x32 inches. The positives are of the standard Manchester type. Each tank is 21½ inches wide by 79¾ inches long by 43⅞ inches high and weighs 6,200 pounds. The total weight of the battery, exclusive of conductors, is 1,029,200 pounds. The tanks are constructed of 2-inch ash, lined with 5-pound sheet lead. They are each supported on ten double petticoated insulators resting on tiles laid on the acid-proof floor.

CONDUCTORS.

The end cells are connected to the end cell switches by lead-covered copper bars 6x½ inches, supported by insulators resting on iron girders strung between the columns of the building. The main connections of the battery consist of two copper conductors, giving a sectional area of six square inches. The lead coating of the copper is a special feature, which renders the copper impervious to the action of the acid and gases.

END CELL SWITCHES.

There are three end cell switches on each side of the system. These switches have 30 points and are capable of carrying 2,750 amperes each. The connection between the 30 contacts and the bus-bar of the switch is made by a laminated copper brush traveling on a screw operated by ½ h. p. series motor. These motors are put into operation by push buttons on the controlling switchboard, but are stopped automatically when the brush reaches the mid-point on the contact block by an automatic device, which breaks the motor circuit and short circuits the armature. The method insures the positive action of the end-cell switch without requiring attention of the switchboard operator. These switches are provided with a hand wheel for hand operation if desired. The gear wheels are arranged so that the three switches can be geared together and operated as one switch, thus giving a capacity of 8,250 amperes on each side of the system.

CONTROLLING BOARD.

The controlling board is connected to the bus-bars of the end cell switches by 12 cables of 1,500,000 cir. mils each. On the controlling board there are three single-pole switches for each end cell switch, enabling it to be connected to either the mains, auxiliary or charging busses. Each end cell switch has an indicator on the controlling panel operated mechanically by light shafting and gearing, which shows the operator the exact position of the traveling brush on the end cell switch at all times. On each panel of the board there is a 30-point voltmeter switch connected to a low-reading voltmeter, which enables the operator to take the voltage of the end cell switches.

One of the important features in connection with this battery installation is the method of charging without the use of boosters, which are ordinarily employed in most battery installations. The method of charging in the Chicago Edison battery installation is to operate a pair of 200 k. w. machines in the Harrison street station at about 180 volts, which is the voltage required for charging, and send the current over a portion of trunk line from Harrison street to the battery station at Adams street. The voltage regulation of the dynamos is effected by an automatic control of the field resistance by means of small motors, which are controlled by the operator in the battery station at Adams street, small lead-covered cables being run from Adams to Harrison street, connecting with the motors controlling the field boxes.

These generators, which are used for charging, are not generators specially made for the purpose, but are the same ones which at other periods of the day are used to feed into the main bus-bar of the station, thus saving an investment of about $15,000 in boosters, as well as providing a system of charging, which is very much more economical than the one in which boosters are employed.

The battery will be kept in circuit at all times during the daytime in summer, "floating" on the circuit, keeping the engines at the Harrison street central station working at their most economical point, the battery being ready at any time to take care of any sudden increase in load which may occur in the system, as well as taking care of the peak in winter time, for which purpose it was primarily purchased. By maintaining the battery on the circuit continually the necessity for regulation of pressure at the central station is very much lessened.

The battery was furnished, as well as the entire installation carried out, by the Electric Storage Battery Company, of Philadelphia.

The Electrical Engineer, it may be added, has from time to time noted the growth of the Chicago Edison Company, including this last development, and it is not now necessary, therefore, to go into all the familiar details again. In its issue of January 23, 1895, The Engineer devoted a score of pages with some thirty fine illustrations to the work of the Chicago Edison Company, and to the article would refer its readers. As a fitting supplement, however, to its article on the storage system, and to give an idea of the huge generating plant which the batteries reinforce, we reproduce herewith the cut giving a view of the interior of the Harrison street station. Our issue of May 26 presented the annual report of the Chicago Edison Company, and we have just printed, as above noted, the lecture by Mr. Samuel Insull, based largely on his work in the management of the Edison central station system and the other plants of the company.

Throwing Out Welsbach Burners.

ABOUT a year ago, it would appear, Welsbach burners were introduced in the Federal Building at Toledo, O., and a saving over electricity of $1,000 a year by the return to gas was expected. But the Welsbachs are now coming out, and the Toledo Consolidated Electric Light Company has the contract for the ensuing year. In the Post Office the effect of the Welsbachs was particularly disagreeable. In the mailing room the burners are said to have raised the temperature several degrees above the ordinary, and the general influence on the workers was bad. Now that the summer is coming on, such ill effects would be accentuated, but the reversion to electricity is made in good time, and the men will not only enjoy a healthy method of illumination but be able to avail themselves of electric motors from the same circuits. There is no question that the Welsbach is an improvement over the ordinary naked gas jet, but when it comes to permanent competition with electricity it is not in the race at all. It is a makeshift that has been chiefly recommended by its alleged superior economy.

BOSTON.—The Boston Electric Light Company, in its annual report shows earnings of 13 per cent. It is paying 6 per cent. The stock is selling at 120.

Vol. XXV. NEW YORK, JUNE 9, 1898. No. 527.

Single Phase Alternating Current Work as Exemplified at St. Louis.

FOLLOWING our usual custom of presenting in connection with the annual meeting of the National Electric Light Association some striking feature of central station work, we have on the present occasion gone westward and selected the work carried out in St. Louis. The stations and systems of the Missouri Edison Electric Company deserve more than passing notice for several reasons. We believe that we are not wrong in asserting that the conviction has become firm in the minds of central station managers that so far as transmission of current, as distinguished from local distribution, is concerned, there is only one method now worth discussing, and that is the alternating current. But, on the other hand, it cannot be said that the means and methods by which the alternating current can be applied have yet crystallized into a standard system. By this we mean to say that there is by no means unanimity of opinion as to whether the single, the two-phase or the three-phase system of transmission is best adapted for transmission work within cities. In our issue of January 6, of this year, we described the new system of the Brooklyn Edison Company, in which three-phase current has been employed as a basis, from which all other currents for distribution of whatever kind are derived. In the present issue we present what is without question the highest development thus far reached in single-phase alternating current distribution in the United States, if not in any other country. Mr. Herbert Wagner has for years kept in mind the desirability of utilizing one set of generating machinery for every possible use which could be called for on the consumption circuits, and having started out with the single-phase alternating current he has kept his original object constantly before him. How well this talented young engineer has carried it out will be gathered by a perusal of his timely and valuable contribution to central station literature, which appears in this issue. Mr. Wagner's article embodies a number of fundamental principles, without which alternating working on a thoroughly economical basis cannot be obtained. The first of these which will strike the reader is the fact that the alternating generators are operated in synchronism, as distinct from the old and still very general practice in this country, of operating each machine independently of every other. There is no question that some types of alternators are better adapted to synchronous operation than others, but that all can be so operated is now conceded to be a fact. Perhaps, as Mr. Wagner remarks, it is usually the case that both the dynamos and engines may be a little to blame for non-success in synchronous working. But it only requires perseverance and the application of a little experience to bring about the desired result. In the case of the engine particularly, the application of the Rites regulator seems to have done much towards accomplishing the desired result. Mr. Wagner has also perhaps developed far beyond any other central station manager the application of the single-phase alternating motor to power work, and has shown that this machine, notwithstanding the persistent criticisms brought against it, can, under intelligent management, be made to fulfil the mission which has in the past largely been delegated to the direct current motor. As to the underground distribution system, Mr. Wagner has evidently planned very carefully, and his claim for an efficiency of 95 per cent. between generator and lamps, including the transformer, on a 20 per cent. load, places his system even beyond the best economy attainable with direct current systems.

But what will perhaps be considered the most striking feature exemplified in the work at St. Louis, is the operation of arc lamps in series, with alternating current derived directly from the same generators running the incandescent circuits. It is perhaps in this direction that Mr. Wagner has struck out in the most original way. The use of the constant current alternating transformer with regulator permits of lamps being run in series in exactly the same manner as from the direct current arc machines, but evidently with a far greater economy due to the fact that the load is taken off machines of 1,000 k. w. capacity as compared with the older maximum 100 h. p. direct current arc machines. The details of this system are particularly worthy of study, as they represent a method of working which seems destined to wide application in the future.

While the station at St. Louis represents what is without doubt the highest development of single-phase alternating current work, the direct current for local distribution is still with us, and, if anything, is obtaining a stronger hold than ever before. An exemplification of this fact is the installation of the great storage battery in the Chicago Edison Company. Taking the plants at St. Louis and Chicago side by side, for example, it seems harder than ever to formulate a definite opinion as to the ultimate outcome of the struggle for supremacy which has been waged the past dozen years between the direct current and the alternating current. In fact the situation seems to be that, with intelligent management, either system can be made to give good results; and while there may be slight advantages as to cost and other incidental features on one side, there are on the other hand offsets which counterbalance these advantages. We trust that the topic as exemplified in the two stations above referred to, including that of the new Brooklyn station, may come up for discussion at the convention. Some of the most prominent electricians of the country will be present, and the members will no doubt gather a few grains of experience well worth the trip to Chicago.

The Liquefaction of Hydrogen and Helium.

LINKED together by vast commercial interests as well as by close scientific relations, the sciences of electricity and chemistry have each had a decided claim on the attention of investigators in either field ever since Galvani and Volta were engaged in their celebrated controversy over the origin of the electric current in a voltaic cell. The analysis of water by means of the electric current and the investigations of Faraday, which led him to the discovery of the laws of electrolysis, giving us a clearer conception of electrical phenomena, as well as the later commercial production of calcium carbide, disinfectants, and other products by means of the electric current, including the reduction of metals from their ores, have all demonstrated the great value of electro-chemistry and its revolutionizing influence on the arts. It is but natural then that the electrical engineer and investigator of to-day should be keenly interested in the labors of his fellow scientist, the chemist, knowing as he does,

that every discovery in chemistry can be advantageously applied to some engineering process or aid in elucidating the mysteries of the electric current. However long these may remain hidden from the human understanding, a problem equally obscure and interesting is the one of the change of the properties of substances at or near the absolute zero of temperature. That this can only be reached by the liquefaction of gases has been known for a long time, and all but two gases had been liquefied until recently, when, on May 10, Professor Dewar succeeded in liquefying the two remaining gases—hydrogen and helium. This epoch-making discovery, the far-reaching importance of which cannot be overestimated, was communicated by Prof. Dewar to the Royal Society in a most interesting paper. The hydrogen was cooled to — 205° C., and escaping continuously under a pressure of 180 atmospheres from the nozzle of a coil of pipe at the rate of 10 to 15 cubic feet a minute, in a vacuum vessel doubly silvered, and of special construction, surrounded with a space kept below — 200° C. With these arrangements liquid hydrogen began to drop from this vacuum vessel into another, doubly isolated by being enclosed within a third, and in five minutes 20 cubic centimeters of liquid were collected. The hydrogen jet then froze up from the solidification of air in the pipes of the apparatus. The yield of liquid was about 1 per cent. of the gas. In a subsequent experiment five gallons were produced in one hour. In the liquid condition the hydrogen was clear and colorless, showing no absorption spectrum, and the meniscus was as well defined as in the case of liquid air. The liquid in Prof. Dewar's opinion must have a relatively high refractive index and dispersion, and the density must be in excess of the theoretical values, viz., 0.18 to 0.12, deduced respectively from the atomic volume of organic compound and the limiting density found by Amagat for hydrogen gas under infinite compression. The second experiment was with a tube containing helium. The Cracow Academy Bulletin for 1896 contained a paper by Prof. Olszewski, entitled "A Research on the Liquefaction of Helium," in which he stated that, as far as his experiments went, helium remained a permanent gas, and apparently was much more difficult to liquefy than hydrogen. Prof. Dewar, however, suggested and showed that hydrogen and helium had about the same volatility as was the case with oxygen and fluorine. Having a specimen of purified helium, extracted from Bath gas, sealed up in a bulb with a narrow tube attached, he placed the latter in the liquid hydrogen, whereupon a distinct liquid was seen to condense. In conclusion Prof. Dewar pointed out that all known gases had now been condensed into liquids which could be manipulated at their boiling points under atmospheric pressure in suitably arranged vacuum vessels, though even so great a man as Clerk-Maxwell had doubts as to the possibility of ever liquefying hydrogen. With liquid hydrogen as the cooling agent a temperature could be reached within 20 or 30° of the zero of absolute temperature, and its use would open up an entirely new field of scientific inquiry.

This great discovery and the production of liquid hydrogen in large quantities will no doubt open up new fields for scientific investigation and aid us in our endeavors to look further into Nature's workshop, to discover the constitution of matter and perhaps the transmutation of metals and the nature of electricity itself.

Our Supplement.

As bearing closely on the subject of the relative advantages of the different systems for city transmission work, we present with this issue a chart carefully worked out by Mr. A. B. Herrick, showing the limits within which the various systems can be profitably employed. With this chart before him, the electrical engineer, knowing the amount of power required to be delivered at a given distance from the station, is enabled to tell almost at a glance what system will prove best adapted to the conditions. The curves on the chart indicate some very interesting relationships between the various systems, and their intelligent study may prevent some serious mistakes on the part of those contemplating extensions of territory.

OBITUARY

Dr. Charles E. Emery.

Charles E. Emery, Ph.D., died at his home in Brooklyn on June 1 of heart failure. He was a consulting engineer of no little repute in this country. He was born in Aurora, N. Y., in 1838. In 1861 he entered the Navy and was appointed third assistant engineer with a post on the warship Richmond. He fought in the battle of Pensacola and accompanied Farragut in the famous series of battles on the Mississippi. His good work during these engagements led to his promotion as second assisting engineer in 1862 when he took part in the blockading of Charleston. After honorable service during the entire war he resigned in 1867 and was appointed consulting engineer in the United States Coast Survey and Revenue Service. In this position Mr. Emery had charge of the construction of war vessels and revenue boats for the Government, until the work was finally put into the hands of a Navy Yard Department. His title of Ph.D. was conferred upon him by the University of New York as an appreciation of his work. He added to this distinction by receiving the Telford prize for the best paper read before the English Civil Engineers in London, some time in the eighties. He was always a prominent member of the American Society of Mechanical Engineers and was president in 1896-7 of the New York Electrical Society, as well as a member of the American Institute of Electrical Engineers. He was a non-resident professor of Cornell University and his lectures on engineering matters have been heard in all the prominent cities of the country. He was also a member of the American Society of Civil Engineers.

As an expert in engineering matters, he has figured in many Brooklyn water litigations, and recently he was interested in the damage cases resulting from the flood in Bound Brook, N. J. He was not only an engineer in theory, but in actual practice and had several patents for important improvements in machinery. He was connected with the New York Steam Company as consulting engineer at the time of his death.

Mr. Emery left a wife and one son. The funeral took place from his residence, Greene avenue, Brooklyn, on Friday.

LITERATURE

HOW TWO BOYS MADE THEIR OWN ELECTRICAL APPARATUS. By Thomas M. St. John. Publisher same. New York. Cloth. Illus. 141 pp. Price, $1.

The author of this book is a teacher and writer of great ingenuity, and we imagine that the effect of such a book as this falling into juvenile hands must be highly stimulating and beneficial. It is full of explicit details and instructions in regard to a great variety of apparatus, and the materials required are all within the compass of very modest pocket money. Moreover, it is systematic and entirely without rhetorical frills, so that the student can go right along without being diverted from good helpful work that will lead him to build useful apparatus and make him understand what he is about. The drawings are plain and excellent. We heartily commend the book.

PERSONAL

COL. C. E. McCLUER, the Richmond, Va., superintendent of the Southern Bell Telephone Company, has resigned and has been succeeded by Mr. Hunt Chipley, of Norfolk, Va.

The First Electrical Wedding.

A very unique and interesting wedding was celebrated at the Electrical Exhibition on Wednesday, June 1, at 9 p. m., when Mr. Charles Sanford Merten and Miss Jennie S. Gilmour, of the Boroughs of Bronx and Queens respectively, were joined in wedlock in the Moore chapel by an assistant of the Rev. Dr. Houghton, of the Church of the Transfiguration. The Mendelssohn and Lohengrin wedding marches were played on an Estey pipe organ run by an electric motor, and later in the evening a phonograph played hymns. The chapel was brilliantly illuminated by Moore tubes and beautifully decorated, and the general effect was as imposing as it was impressive. A very august assemblage was present, and the bride was given away by Mr. C. O. Baker, Jr., the president of the Exhibition, and Mr. Marcus Nathan, the general manager of the Exhibition, was the best man. To make the electrical wedding a complete success and novelty, both bride and bridegroom came to the wedding in electrical carriages from their respective homes.

Armington & Sims Co.'s Exhibit.

THE Armington & Sims Co., of Providence, R. I., builders of the well known automatic cut-off high speed engines, are exhibiting in the generating section a 100 horse power 90 lbs. 275 r. p. m. engine direct connected to a Walker generator. It is one of the 1898 pattern high speed engines which embodies the devices and improvements which long practical

ARMINGTON & SIMS ENGINE DIRECT CONNECTED TO A WALKER GENERATOR.

experience has shown to be essential to the highest efficiency attainable in engines of this character. Most important among these improvements are the self adjusting cylindrical or piston valve, the Rites inertia governor, and the oiling devices. The exacting requirements of electric railway and lighting service have called for engines of massive construction, with the metal properly distributed to insure absolute rigidity throughout. All these requirements will be found to be satisfactorily met in this engine; indeed, they will generally be found to be somewhat heavier than corresponding sizes in the product of other builders.

Onondaga Dynamo and Fischer Engine Exhibit.

ONE of the quietest running units in the generating section is that exhibited by Messrs. Fairchild & Sumner and Porter & Remsen, 39 Cortlandt street, New York. It consists of a 6-pole engine type, 75 kilowatt Onondaga dynamo, direct connected to a Fischer engine. It furnishes a large portion of the light and power for the exhibition. The Onondaga

EXHIBIT OF ONONDAGA DYNAMO AND FISCHER ENGINE—BASEMENT.

dynamo possesses many admirable features. The magnet yoke is made of a special mixture of gray iron and is generous in proportion and neat in design. The magnet cores are made of soft charcoal forged iron, and are cast welded into the magnet yoke, thus doing away with all unnecessary bolted joints. The bearings are self-aligning, self-oiling, and of the ball and socket type. The brush holder is so designed that a uniform bearing is obtained with a minimum pressure, thereby causing a small amount of friction on the commutator, eliminating heat due to this friction; carbon brushes are used. Messrs. Fairchild & Sumner report large sales of the Onondaga machines, a recent installation consisting of two direct connected machines at the New York and Staten Island Electric Co.'s new power house at Livingston, Staten Island, and a large dynamo and several motors to the Atlas Cement Co., of North Hampton, Pa.

The Fischer automatic self-oiling high speed engines are made of either the single or four-valve type, the engine at the exhibition being a 125 horse power, four-valve tandem compound direct connected engine. The main features of the engine are the oiling device and the strength and simplicity of the construction throughout. The oil is contained in a large settling tank around the crank case, the oil passing from this to the main bearings, crank pin, crosshead pin and slide and valve rod slide and pin and thence back to the settling tank, all of the oil not actually lubricating the moving parts being contained in the tank where it cools and settles and again passes through its course. The crank case has a partition keeping it separated from the stuffing box, thus keeping the oil from being thrown against the cylinder-head and the steam and water which may leak through the stuffing from mixing with the oil. The valves are adjusted from the outside, it being unnecessary to remove the valve chest covers or use the indicator after the valves have been set at the shop. There are no keys or screws in the machine which can work loose and cause damage while the engine is running. A "Corliss" card is obtained from the four-valve engine, and on larger sizes a steam consumption equal to that of the best Corliss engine is obtained. The company are prepared to demonstrate these claims by actual tests at their works to anyone interested, and all engines are thoroughly tested under working conditions before leaving the shops. The Fischer Foundry & Machine Co. have a complete modern plant thoroughly equipped for turning out horizontal or vertical engines of either the centre or the side crank types. The success of this company during the forty years they have been in business is a guarantee of the quality and workmanship of the material sent out by them.

Although the engine is practically new in the Eastern market, the number of orders received during the last few months should indicate that success is assured. One of the latest sales is that of a valve direct connected engine to the Union Traction Co., of Philadelphia. The company are represented in New York by Porter & Remsen, 39 Cortlandt street, and they have offices in Philadelphia, Chicago and Boston. The exhibit is in charge of Mr. F. H. Sheppard.

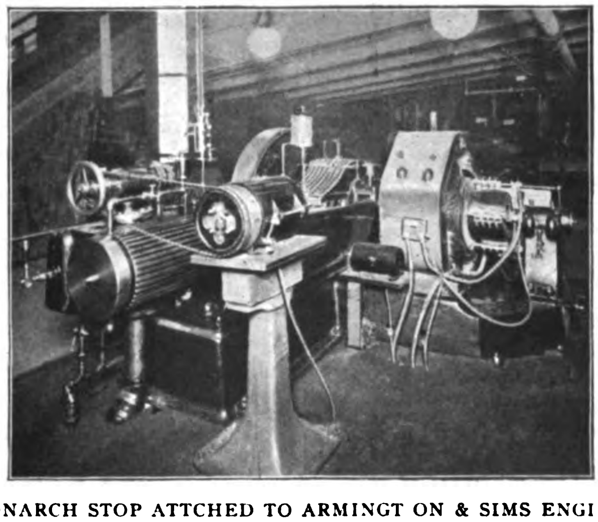
Operative Exhibit of the Monarch Manufacturing Company.

ONE of the most interesting exhibits in the generating section is that of the Monarch Manufacturing Company, 39 Cortlandt street, New York. From this exhibit one can easily understand the working of the well known Monarch engine stop and automatic speed limit, which are shown in actual operation. The Monarch stop can be seen mounted upon one end of a table, while an eight-inch globe valve is shown at the opposite end, connected by sprocket wheels and chain to the stop. This globe valve may represent the throttle valve on an engine's cylinder or a stop valve on a boiler, both being handled alike by the Monarch stop. As a hand wheel is turned to open the valve the two sprocket wheels and chain cause the drum of the stop to revolve around its central shaft, and while thus revolving it winds a flexible wire cord around itself, elevating weights which are connected to the opposite end of this wire cord. When these weights are elevated, it indicates that the valve is completely open, allowing steam to pass through.

A number of electric push buttons are placed in various positions about this booth, and when any one of these is touched a temporary magnet in the engine stop is energized, which attracts an armature and releases the mechanism which holds the weight in the elevated position shown, and the valve is thus closed in three seconds after making the twelve turns which are necessary to send it from a full opening to a complete closure.

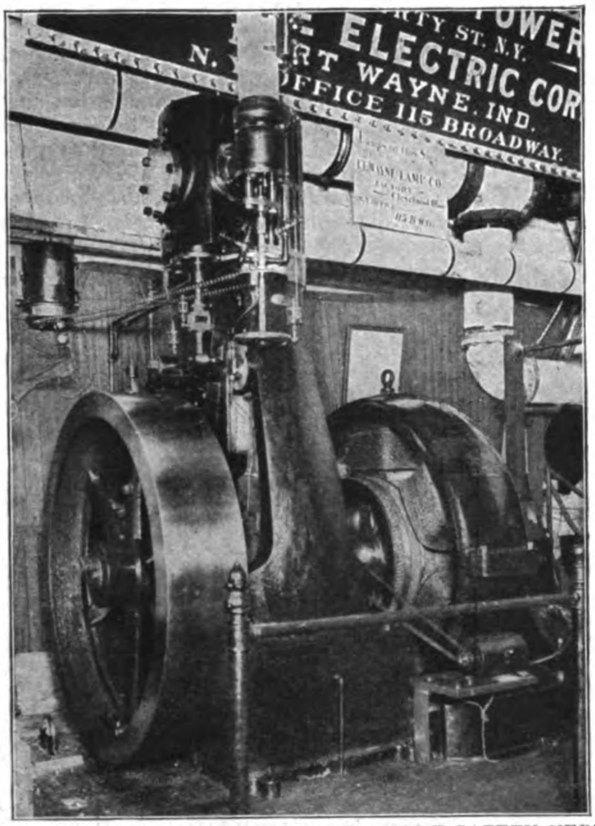
On a front counter at the left one of these engine stops is shown with the cover raised and at the left, inside of this stop, a large air dash-pot or air cushion can be seen. The office of this dash-pot is to arrest the very rapid motion of the closing valve just before it reaches its seat, thus causing it to seat easily but still firmly. If this provision were not made, the seats of the valve would soon be destroyed, as may be easily understood. At the same time that one of these electric push buttons is touched an electric gong at the rear of the booth begins to ring, thus notifying an engineer that his engine or boiler valve is being closed from some distant point, and this bell will continue to ring until either the switch contained in the stop is thrown out, or the stop mechanism is reset ready for the reopening of the valve.

Mounted on a table at the left of the exhibit is shown a Monarch automatic speed limit, while on the front counter at



MONARCH STOP ATTCHED TO ARMINGT ON & SIMS ENGINE.

the left can be seen a second speed limit with its cover raised. In actual service this device is belted directly to the crank shaft of an engine and is thus kept revolving whenever the engine is in operation. By examining its construction it will be found to contain a governor composed of two balls, each one being mounted upon a flexible flat leaf spring. These springs are fastened securely at one end to a collar fixed upon its central shaft, while the opposite ends are connected to a second collar which slides backward and forward upon the shaft, its position being determined by the size of the circle described by the two governor balls. When the speed of this instrument is increased beyond a certain number of revolutions (which correspond to



MONARCH STOP ATTACHED TO NEW YORK SAFETY VERTICAL ENGINE.

the normal speed of the engine) the sliding collar makes a contact with two separated fingers, from which electric wires are run to the stop. As soon as this contact is made the circuit is closed, and the valve is rushed to its seat in precisely the same manner that it is operated when a push button is touched. Thus it will be seen that when the revolutions of the engine exceed a certain predetermined safe speed, its throttle valve is closed almost instantly, thus making a fly wheel accident impossible and also preventing a wholesale blowing of fuses.

In this exhibit a Crocker-Wheeler motor is substituted for the revolving crank shaft of an engine and by means of a rheostat the speed of the motor can be easily varied. When the motor is revolving at a speed that drives the speed limit about 400 revolutions per minute the speed limit does not affect the stop, but as soon as the handle of the rheostat is turned, causing the motor to increase its speed the stop valve is closed immediately, as has just been described.

In order to illustrate the sensitiveness of this instrument a Schaffer & Budenberg tachometer is connected to it and from this tachometer the exact speed at which the speed limit is being operated can be easily read off and by its use it is shown that the excess of even one single revolution above the 400 revolutions (to which speed this instrument is set) will cause it to close the electric circuit and thereby cause the stop to close the valve.

At the rear of this exhibit is shown the Monarch stop controlling an A. & F. Brown friction clutch, which clutch is disengaged instantly by merely touching any one of several push buttons placed about the booth. When a button is touched and the elevated weight allowed to fall, the revolving sprocket wheel draws its encircling chain with the clutch lever attached in the direction necessary to throw out the clutch. The clutch pulley is revolved by a small Crocker-Wheeler motor and when the clutch is thrown in, by moving the lever towards the pulley, the shaft, of course, revolves; and as soon as one of the push buttons is touched the Monarch stop causes the lever to be

pulled away from the clutch pulley and the main shaft ceases to revolve instantly. By this device it can be seen that when the Monarch stop is applied to a clutch, press buttons may be run to various points in a factory, some being placed upon dangerous machines, so that in case any one is caught in a machine belting or shafting they can press the button and stop the machinery instantly.

The illustrations show the application of the Monarch stop and automatic speed limit to the large vertical engine exhibited by the New York Safety Steam Power Company, and to the Woodbury engine exhibited by Messrs. Burhorn & Granger. The apparatus have attracted a great deal of attention and have received many favorable comments from the numerous visiting stationary engineers who can readily appreciate their great advantages. The genial general manager of the company, Mr. Albert A. Cary, was in constant attendance to explain and to answer the numerous questions asked by interested parties.

Exhibit of the Hebrew Technical Institute.

LOCATED on the balcony to the right of the main entrance, is the very handsome and instructive exhibit of the students' work of the Hebrew Technical Institute, which has attracted considerable attention during the past few weeks, not alone on account of the variety of apparatus shown, but also on account of the youth of the boys who designed, constructed

HEBREW TECHNICAL INSTITUTE EXHIBIT.

and used them. The following machines and measuring instruments are exhibited, which give a fair idea of the excellent work done by the pupils of this well known institution: A 1 k. w. Edison bipolar dynamo, two Thomson reflecting galvanometers, a Faraday disc dynamo, four resistance boxes, a large pair of electro-magnets, an astatic and tangent galvanometer, a bichromate battery, a Wheatstone slide wire bridge, frictional electrical machine, four medical coils, etc. The boys designing and constructing this apparatus are between the ages of thirteen and sixteen, and it is clearly seen that the essential fact is impressed upon the student's mind that he must design commercially practical apparatus and not violate scientific principles. The course in electricity, for these reasons, has been aptly termed "a course in practical electricity." The note books exhibited give a good idea of the wide scope of the experimental work done, including many tests on primary and secondary batteries, the tracing of magnetization and permeability curves, calculations of magnetic circuits of various types of dynamos and motors and tests of dynamos, arc lamps and meters. The note books are neatly kept and each experiment is accompanied by a sketch, photograph, or blueprint. By means of small models the boys are shown how to trace out magnetic fields and on large porcelain slabs are shown by means of iron filings the results of this diligent work.

There is also shown a vertical section of a dwelling house containing in the basement engine, boiler and dynamo. The house is completely wired for six incandescent lamps and the dynamo is run as a motor from an outside source, driving the engine instead of vice versa, which of course is not apparent to the casual observer and does not detract from the usefulness and beauty of the apparatus. The electro-mechanical work is carried on under the direct supervision of Mr. E. V. Lallier, while Mr. W. W. Ker assumes all responsibility for the theoretical instruction including experimental work. The success achieved by the graduates of this institution in the electrical field speaks very highly for the splendid course taught by these two gentlemen. Mr. Ker, in particular, has been wonderfully successful in teaching theoretical and thoroughly practical electricity to boys of such extreme youth. The school is located at 34 and 36 Stuyvesant street, and contains perhaps the most complete electrical laboratories and well equipped shops of any educational institution of a similar kind. The instructors have arranged a collection of practical appliances loaned or given by manufacturers which aids materially in conveying to the boys an idea of apparatus in every day use. The next class will be graduated on June 23, and equipped as they are with the splendid training received at this school they should have little difficulty in obtaining positions.

Exhibit of the Cleveland Twist Drill Co.

THE Cleveland Twist Drill Company, 99 Reade street, New York, exhibited at the Electrical Exhibition in a handsome glass case, a large variety of twist drills, reamers, cutters, oil tube drills, etc. The exhibit shows up the fine workmanship of the company, as well as the great variety of tools which they manufacture. One of the features shown is the electrician's bit and fish wire combined. By means of the holes drilled through the centre web of these bits, electricians can fish their wires without the use of a secondary tool for that purpose. All bits up to and including 10-32-inch diameter have "fish holes" for No. 14 wire, after the insulation has been removed. Larger bits will be provided with larger holes, if required. All bits are made from the best steel, and are said to be the finest finished

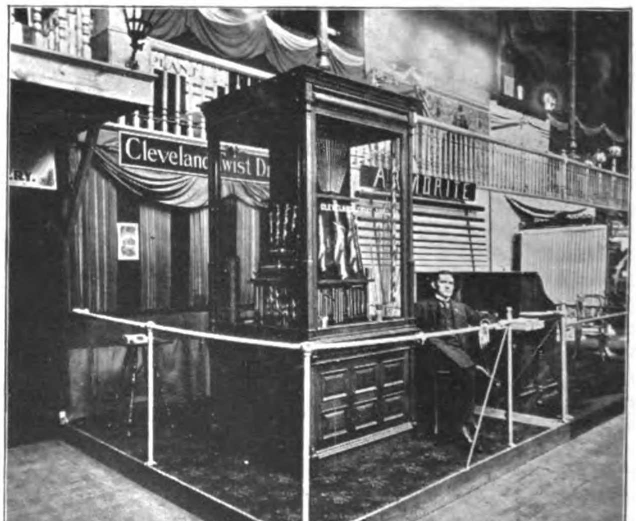


EXHIBIT OF THE CLEVELAND TWIST DRILL COMPANY.

tools on the market. A very pretty souvenir in the form of a nickeled twist drill, to be used as a watch charm, is given away by this enterprising company. Mr. E. H. Jung was on hand to answer all inquiries regarding the company's products.

TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work.—XIII.

BY A. E. DOBBS.

HINTS ON EXCHANGE MANAGEMENT.

THE most important details connected with telephone work relate to the central office itself, and one of the most important of these is in regard to the service rendered.

Telephone service, to inspire confidence must be prompt and reliable, and a manager with comparatively inefficient instruments and lines, who looks sharply after the service and keeps his trouble out, will be on a great deal better terms with his subscribers, than one who, having the very best instruments and lines that experience and money can procure, neglects this important condition. For the best instruments now made will occasionally go wrong. No matter how carefully lines are built, they will sometimes break or cross.

Let us cite an example: A and B are rival managers of two exchanges in the same town, and both have about the same number of subscribers; A has a good plant and instruments that are up to date, but he cannot be made to see the necessity of attending to service details. His operators do not always attend strictly to business, and he never seems to find it out. Lines may get in trouble and remain so for a week (this is no exaggeration), and even when the operator reports a line as working badly, he seems to think that he has other work of more importance to attend to, so that the operators have got discouraged and quit reporting trouble. His employés, too, have caught something of the same spirit and have got into the habit of "letting things go." B, on the other hand, looks sharply after his trouble and instructs his operators to report it promptly as soon as discovered. His tours of collection are tours of inspection as well, and his operators understand that if they do not answer calls promptly they are liable to have some one else filling their places. Whenever he is in office he will take pains to call their attention to calls that are not answered as they should be, not harshly, for he is one of the best fellows alive; but attending strictly to business himself and all his office employés understand that they are hired to do the same, not to gossip or read novels, and that patrons must get the service they pay for, and in disputes between operators and subscribers, which will occur in the best regulated exchanges, they know that he will stand by them unless they are altogether in the wrong.

No matter what work he has on hand, trouble must be taken care of as soon as reported, even though a whole gang of men is kept waiting.

Now all this seems severe, yet his general good nature and unfailing courtesy make him a favorite both with employés and subscribers, and in the course of a year he begins to cut into his opponent's subscription list and A is still wondering why people prefer B's service to his own, forgetting or not knowing that his own neglect created grumbling, induced lack of confidence, and made enemies of the very men who were helping him in his business.

When a subscriber finds that he cannot raise "Central," he feels exasperated and not without reason, as he is paying for a continuous service, and has learned to depend upon the telephone the same as he would upon an employé, with this difference, when an employé is sick or absent the fact is generally known, and arrangements made to fill his place; but with a telephone out of order the fact is not discovered, perhaps, till the busiest part of the day, and its place can only be filled by a messenger. Again in some offices where there are only from 50 to 200 subscribers, the operators are perhaps young and giddy girls, or still more young and careless boys, who cannot always understand—unless reminded of it—the necessity of answering a call the very instant that it comes in. Perhaps they want to get to a stopping place in the book they are reading, or finish an interesting gabble with some clerk or "lady friend," while the impatient subscriber has to wait 10 or 15 seconds, which seem like so many minutes, and perhaps has to ring another time or two, before he is answered. Soon he begins to talk among his acquaintances about the "one horse exchange" and "poor service," and some day he goes over to the opposition company and perhaps takes some of his friends along with him. You may think that certain men are too mean to have any friends, but nearly all mankind is more or less amenable to suggestion, and while the above remarks may have no present influence, yet the people to whom they are made will remember them the very first time they have trouble with their own instruments.

Now all operators are not like this, but business heads cannot be expected on young and inexperienced shoulders, and the best of them need watching occasionally. Do not let them forget that they are there to serve the public first of all and remind them that troubles discovered should be promptly reported, and give them to understand that they will be as promptly attended to.

The saying of a Western electric light manager is apropos, "Keep the lights going, if the engine goes in the scrap heap to-morrow," which, being applied to telephone service, means: A subscriber wants to be answered as soon as he calls, and he wants the exchange every time he calls.

But prompt service is not the only thing necessary in training operators.

The work of operating a busy switchboard is confining and often irritating. The very best systems yet devised have their faults, and some of the newer boards have many. Subscribers feeling out of humor show a disposition to find fault, perhaps because the party called for does not answer promptly, or the line is "busy." In large exchanges operators are not allowed to converse with subscribers during business hours and patrons showing a disposition to argue matters are either shut off or switched over to the chief operator, but in the smaller exchanges there is no chief operator; the manager is away from the office fully half the time, and the girl has to bear the brunt of complaints and fault finding alone. In such a case of course the young lady must be schooled to control her temper under all ordinary circumstances.

In a circular issued by certain railroads to employés occurs this sentence:

"Employés should show to patrons the same tact and courtesy that a business man would use with his customers."

It would be well to post this up in every exchange.

Many operators have such pleasant voices and pleasant ways that it is really a pleasure to call up the exchange. What though an operator is "quick as lightning" and can put up plugs at an astonishing rate if her call of "Number!!" makes a timid subscriber start back in alarm, and who upon the least provocation replies in language blunt as well as vigorous? Such a one is not fitted for the telephone business and should try some other occupation. On the other hand, it is worth considerable to an exchange to have its plug manipulators spoken of as "such nice, pleasant girls," "so accommodating," etc. Remember that the public judges an exchange largely by its operators, for, after the instrument is once installed, they see and hear very little of anyone else except the collector. The general public does not know of the work that operators have to do, and to enlighten them it is a pretty good idea to invite them to call and see the exchange in operation, where a little courtesy on the part of manager and operators will prevent a great deal of fault finding and establish a personal acquaintance which will create a better mutual understanding all around. Operators will generally try to please, for approbativeness is a woman's leading characteristic and a hint or suggestion covering these points, will generally be sufficient, for every girl likes to be well thought of.

But there is another quality in a girl's disposition which is not so easily controlled, viz., curiosity.

There is a general disposition on the part of young operators to cut in and listen to conversations, and even in some cases repeating what they hear. Now I know that as long as human nature remains as it is, that it is hard to break up this habit unless she is fully occupied otherwise; but there are several reasons why this is wrong.

Every message between patrons should be regarded, by operators and officials, as confidential, never to be divulged under any circumstances, unless perfectly sure the parties would not object. If, however, the operator stays off the line, she will not hear anything she should not. Again, the girl should be instructed that every time she cuts in she throws either the resistance and self-induction of her own instrument into the line or throws in a "ground" reducing its efficiency in either case by that much. Suppose that two subscribers, owing to long

lines, poor instruments, or a noisy location, can make themselves understood with difficulty, the operator by cutting in will increase the difficulty almost two-fold.

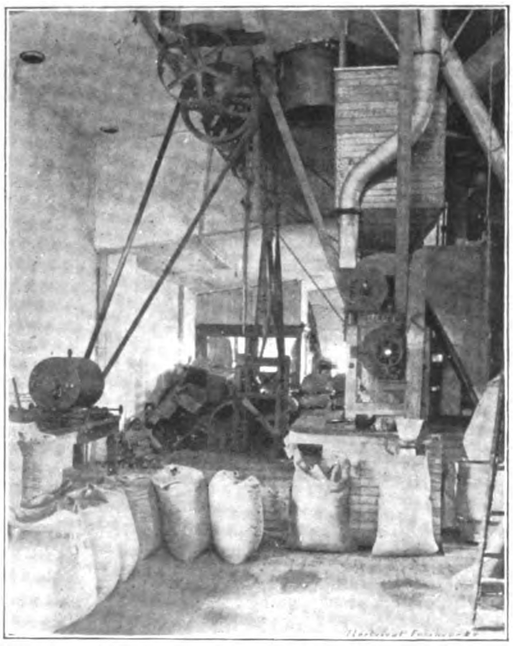
To be sure some patrons will not ring off when through talking, and the operator has to cut in to find out if they are through, but even then it is not necessary to cut in directly, as by putting one hand on the base of the plug and the other on one of the binding posts of the receiver she can shunt enough of the current to hear perfectly everything that is said, and even answer them if necessary. I know of one exchange where the operators use this plan almost altogether for cutting in after the plugs are up, while the high and non-inductive resistance of the body prevents any appreciable loss of current.

Give the girls all the conveniences and comforts that you can. Do not compel them to acquire a lame arm turning a hard, stiff hand generator; if you can procure a steady, reliable power in your neighborhood, such as a small gas, water or electric motor, or a factory shaft running continuously, to turn it for them. Make the place attractive and show them the little attentions which they so much appreciate and the strictest discipline will hardly be felt.

C & C Electric Power Plant in L. H. Parke & Co.'s Coffee Roasting Establishment, Philadelphia.

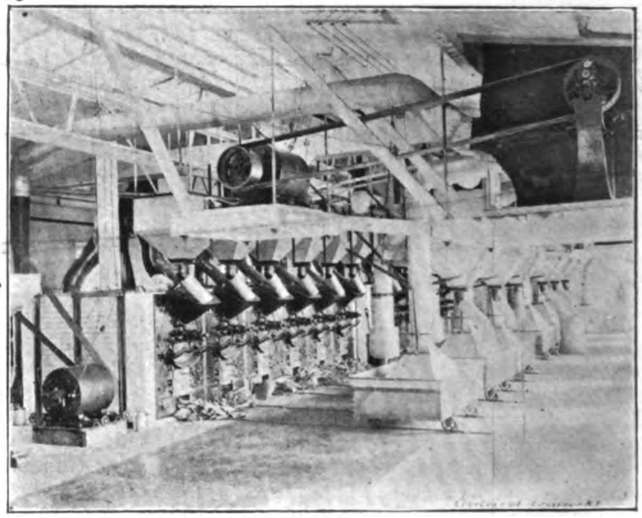
WE have in the past illustrated numerous electric power installations in industrial establishments, but none is, we believe, more characteristic of the adaptability of the electric motor than that recently carried out by the C and C Electric Company at L. H. Parke & Co.'s establishment in Philadelphia.

The former occupant and owner of the present premises occupied by L. H. Parke & Co. since March 1, had installed a side crank Buckeye engine, which drove a shaft on the ceil-



COFFEE ELEVATING AND WEIGHING MACHINE.

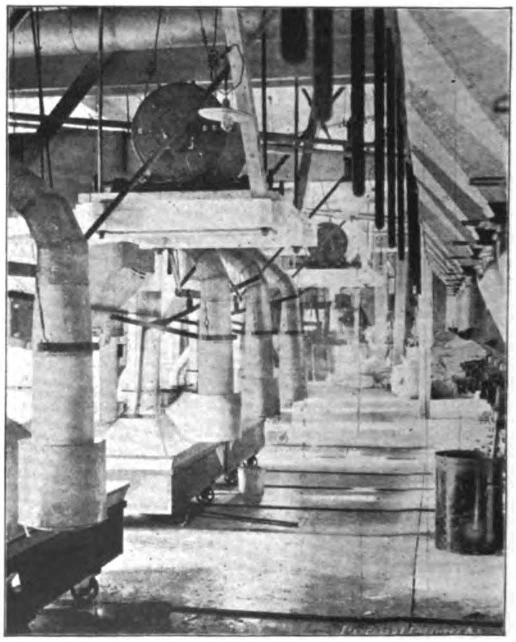
ing of the basement, which shaft in turn drove a vertical shaft to the top floor of the building, where it was necessary to have the power. Mr. Parke, who is quite a mechanical genius himself, and who is acting for a firm comprised of young and very progressive business men, decided to abandon the entire system of shaft and belt transmission, and as soon as they got possession of their present building they called in Mr. William Myers, of the Philadelphia office of the C and C Electric Company, and together with Mr. Parke they designed and installed the present power plant, which consists of a four-pole generator of the C and C company's latest type, for belted work, and eleven of the C and C ironclad type four-pole motors, which are entirely enclosed. These motors range from 5 to 10 h. p. in size, and each motor is belted direct to its work. Under the old system that was in use in this building they could not have delivered more than 40 h. p. on the top floor, whereas they are now



COFFEE ROASTING FURNACES AND COOLING BINS.

using more than 70 h. p. The gain is, of course, in the transmission.

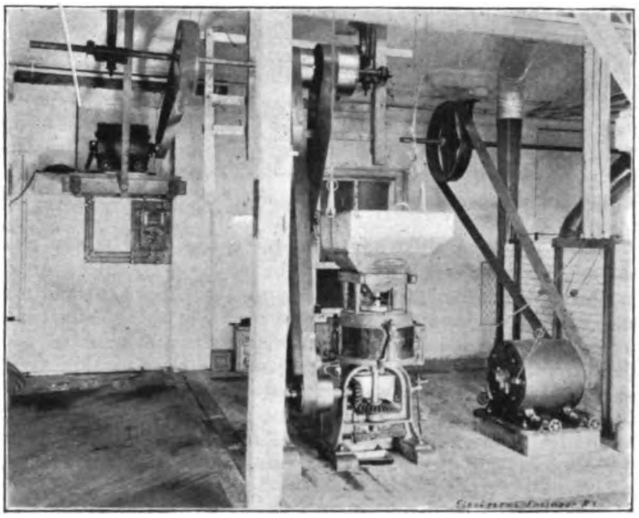
The coffee is brought to the top floor of this building just as it is imported from the foreign countries. It is full of dust, gravel and other foreign matter, which has to be separated from the bean. The coffee is first passed over a picking table, which consists of an endless canvas belt about 50 feet long, which travels at a low rate of speed, and each side of the table is lined with small girls, who pick out the foreign matter somewhat in the way that slate is picked from coal in the coal mines. The



COFFEE COOLING TRUCKS.

coffee then passes into a hopper through a conveyer, built by the Link Belt Engineering Company, which carries it to the milling machines, where all the dust, pieces of twine and any other substances which escape the picking table are separated from the bean, and the bean passes into receivers perfectly clean and graded, there being nothing remaining in the first grade but the largest and purest beans.

These beans are then carried overhead by a bucket elevator, which was also built by the Link Belt Engineering Company, and is emptied into a trough, which runs the entire length of the battery of roasting cylinders. Each cylinder is provided with a hopper, which holds one charge for a cylinder. Directly over these hoppers are slides worked by a lever, and as the hoppers need replenishing the opening is made and the conveyer drops the coffee in until the slide is again closed. The coffee is then



COFFEE GRINDER.

passed from the hopper into the cylinder by opening a slide at the bottom of the hopper.

After being roasted, the coffee is dumped into a "cooling box," which consists of an iron box about 4 by 6 feet and 18 inches deep, and has perforated sides and bottoms. The cooling box is on wheels and is rolled under the cooling apparatus, which consists of a hood, which fits into the top of the box and sucks a strong blast of air through the coffee and out to the open air. In about a minute after the coffee is placed under the cooler, smoking hot out of the roaster, it can be pushed under the stoning machine and carried up to the bin overhead by the suction of

AUTOMATIC PACKAGING MACHINE.

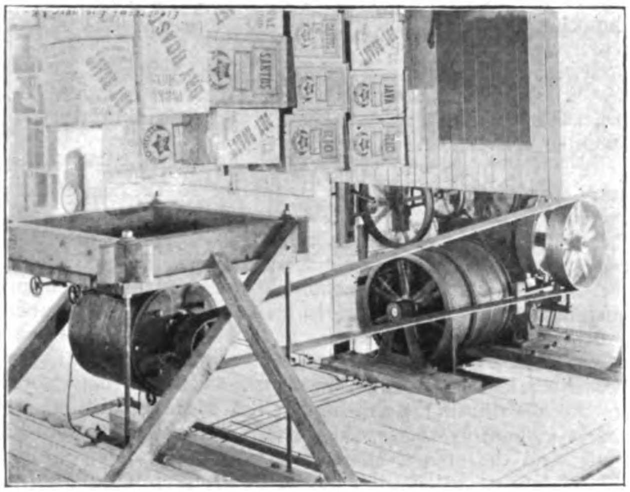
air. This air draught is regulated to a nicety, so that it will leave all gravel or anything which may have escaped the other processes.

From the bins overhead the coffee is passed to the next floor below, where the entire sides of the room are taken up by galvanized iron bins for storage. From these bins the coffee is passed to the third floor, where it is received in bins and hoppers overhead and is weighed and automatically packed in 50-pound tin cans, which are crated, and in one-pound paper packages, which have been treated with a process which renders them air-tight. The coffee is then placed on trucks which run directly on to the elevator and down to the shipping floor, and is immediately shipped out.

The plan of the company is to prepare coffee just as they have orders for it, thereby furnishing their customers always with fresh goods. The capacity of their mill enables them to do this.

The elevator in this establishment is operated by a C and C motor of the ironclad type, 7½ h. p., and is reversible, driving direct on the winding machine, no countershaft being used at all. In the roasting department there are two 10 h. p. motors, each driving a battery of roasting cylinders, and installed in such a manner that the driving shafts of each battery join with a clutch coupling, so that in case either motor should blow a fuse or open a circuit the clutch can be thrown in and the other motor can take care of the load until the repairs can be made. Every motor in the building is equipped with an automatic circuit breaker for overload and automatic release for current interruptions.

There are three 10 h. p. motors connected direct to Sturtevant blowers. There are also motors of various sizes driving the milling machines, granulating mills, pulverizing mills, etc. The accompanying engravings show a number of views in the establishment.



FREIGHT ELEVATOR MACHINERY.

The switchboard, designed by Mr. Myers, consists of two panels, one of which has the Edison service connected to it by double throw switch; the other is used exclusively for the C and C generator. The entire switchboard is connected up in such a manner that by opening or closing the switch the entire switchboard can be used upon either system. There are recording wattmeters for ascertaining the monthly output of the plant, one on the dynamo circuit, one each on the arc light, incandescent light and power circuits.

The plant is well worth a visit to anyone interested in electric power transmission, and Mr. Parke gives a cordial welcome to all visitors.

Electric Power in Lumber Mills.

Among the latest applications of electric power is one in the line of lumber mill machinery. The Westinghouse Electric and Manufacturing Company are installing for the Berlin Mill Company, of Berlin, N. H., two 180 kilowatt 400 volt generators, with a large equipment of their well known type C induction motors, for driving, planing and grist mills, machine shops, and for lighting the plant. The installation is especially interesting as illustrating the use of alternating apparatus for short distance transmission, the extreme distance of any motor from the generator not exceeding 350 feet. Another electrically equipped lumber mill supplied by the Westinghouse Company is that of the M. G. Shaw Lumber Company, of Bath, Me.

MISCELLANEOUS

A Chart For Determining the Most Economical System of Conductors.[1]

BY A. B. HERRICK.

THE general problem of the best conductor system that can be devised to supply fixed centres of distribution with the least first cost and energy loss, involves a number of variables which can be assigned fixed values in order to simplify the problem of the conductor system only, and apply to the different methods commonly used for current distribution.

On sheet No. 1 are laid out centres of distribution at fixed distances from the station. These distances and centres are shown on the right hand margin of sheet No. 1, and each centre has been assumed to take at the peak of the load 5.5 k. w., with a 20 per cent. energy loss.

To make all the systems comparable, it is assumed that the load on the whole system rises uniformly to obviate the equalizing of the feeder loads by the mains.

The vertical line at A is the line from which the weights of copper required for each feeder feeding to each individual consumption centre are laid off horizontally. Each horizontai space represents 10,000 pounds of copper. For individual feeders these weight lengths are included between line A and curved line A B. The aggregate weight of copper required to feed the whole system to any point of the distribution system is included between line A and curve A C.

At B, the three-wire system 110 volts delivered to the mains at 20 per cent. energy loss is applied to the same territory, the line B B being the weight of individual feeders, and B C the aggregate weight of all feeders covering the expansion of the system from the source of generation at B.

At C is shown the application of the single-phase alternating current system 1,012 volts. In this application the copper and transformer is first figured for a 20 per cent. energy loss, and where each transformer is located, its commercial value in copper equivalent is added. This transformer delivers its current to the distributing point under the same conditions as the direct current systems. At D the voltage is raised to 2,024 volts, and the copper again determined for the application to this system of distribution under the same conditions of energy delivery as in the other methods shown. For the range which was selected in order to include the class of problems most generally arising, the three-phase, both delta and Y connection, and the two-phase systems, show too little departure in weight of copper to be graphically differentiated from the single-phase system shown, that is, up to 10,000 feet.

Sheet No. 2 shows the commercial and investment values of these systems. As applied in this case the horizontal lines are dollars, each space representing one thousand dollars. The investments for the two-wire system of distribution are laid off from the line A′, the curve A′ B′ showing the cost for each individual feeder to these points of distribution; and curve A′ C′ indicates the aggregate costs for all copper required to cover this territory. Furthermore, as this copper investment involves an interest and depreciation charge, which must be earned through the sale of the energy it conducts, it is graphically shown that a copper system may be used which will absorb for the fixed charges against the copper cost all possible profit that can be derived from the sale of the energy it conducts.

In order to divorce the variable cost of production from the diagram, it is assumed that the energy is delivered at the feeder having in it a profit of five cents per k. w. hour, the load factor being taken as 30 per cent. Under these conditions the line X Y shows the absorption of this profit by the fixed conductor charges, and after it passes the line A′ to the right it becomes a loss to use this system as a means of supplying energy beyond this point. As the potential increases, this point of loss travels further away from the generating station. The commerical treatment is in the same way taken up for the three-wire system, single-phase 1,012 volts, and 2,024 volts. In the case of the alternating current, the transformer value is added in each case to the copper line value so as to reduce the systems to the same basis of comparison, a transformer of full capacity being used at the centres of distribution.

In the practical application of these diagrams the following points are shown: The exact distance that a given weight of copper will extend a distribution. When using any of the systems illustrated it also shows which system would return the maximum revenue, with a fixed consumption circuit. It is evident that in the problem selected neither a two-wire nor three-wire system is commercially feasible, as the area of loss on the right side of the datum line is greater than the profit area on the left side included between the line X Y and the datum line. If a reasonable profit is desired in distributing to these consumption centres, the graphic method shows that a high potential system should be used when considering the supply of this system from the standpoint of the copper plant only.

Other modifications have to be made which may change the economical area which can be covered by these different systems; the higher the cost of laying the copper the more contracted will become the profitable area for these different systems. All-day losses in the transformer will tend to reduce the difference between the low tension and high tension systems, in regard to the profitable area over which they can extend, but these are conditions external to the copper plant. The graphic method is offered for the purpose of establishing some of the relations in the much involved problem of conductor systems.

[1]The chart referred to forms a supplement accompanying this number of The Electrical Engineer.

Manufacturers and Dealers in Electrical Supplies in Baltimore.—Notes From the Field—III.

BY C. B. FAIRCHILD.

McCAY ENGINEERING CO.

THIS company not only deal in electrical supplies of almost every description, but are also contractors for the installation and equipment of isolated lighting plants, including the engines, both for private and public buildings, parks, steamships and Government signalling stations. They are also agents for the sale of the Interior Conduit Company's products, and also manufacture several specialties, including the McCay regulating socket for alternating current incandescent lamps; they also manufacture marble switchboards for use in lighting and power plants.

The regulating socket is an ingenious piece of mechanism by means of which the candle power of a lamp can be decreased by successive stages from its maximum brightness to a dull red glow, with a corresponding saving of current, and an increase of life to the filament; this is done, however, without the use of resistance coils or other current consuming devices. The advantage and convenience of being able to turn down an incandescent lamp, and yet keep it burning, as can be done in case of a gas burner, is apparent.

The socket proper, by which the above results are accomplished, consists of a hollow metal cylinder about 1¾ inches in diameter and 2 inches in length, the bore being about ¾ of an inch in diameter. This cylinder or core is made up of thin washers of metal, which are stamped out with a die; these are then put together and taped as for a magnet coil. This is then wound in perpendicular coils with a seven wire cable, from which each wire terminates in a separate chamber in a porcelain block, which is adjusted to fit the cylinder, and which carries a small switch by means of which each of the seven wires may be cut out in turn. With all the wires cut in, the light is modified, due to the reactance effect, and the range is from 50 to 5 volts. The sockets are made for a current of 16,000 alternations, and for 50 to 100 volts; also for 7,200 alternations having the same voltage.

The shops of the company are located on German street, and occupy two buildings, with suitable machinery for manufacturing the special products which are put out. Among the machines may be noted a punch, by means of which the washers, composing the lamp sockets are made at the rate of 40 a minute. There is also a machine for drilling marble slabs for the purpose of attaching the switches and instruments, which are required on a switchboard; in this machine a drill is mounted on a radial arm 4 feet in length, thus giving a range for work over a wide slab of marble.

Among the lighting contracts on which the company are now engaged, are the post office at Washington, D. C., with an in-

stallation of 20,000 incandescent lamps, also a motor battery station at Fort Monroe, for the Government, which is to be run by portable storage batteries. There is also a Government contract for lighting on Great Gull Island, in Long Island Sound, opposite New London, Conn.; the power for this plant is furnished by a Hornsby-Akroyd oil engine.

SOCIETY & CLUB NOTES

New Members of N. Y. Electrical Society.

The following is a list of the new members of the New York Electrical Society elected at the last meeting: B. B. Hoffman, Douglass Burnett, Leo R. Manheims, W. S. Atkinson, W. J. Schweiger, John O'Connor, Charles H. Kienle, William W. Rosenbaum, M. J. Adler, George J. Schoeffel, W. S. Alexander, E. Bradford Bumsted, Julius W. Eichler, Arthur H. Brown, Walter A. Houghtaling, Sterns Francis Jones, I. W. Smith, James H. Campbell, Farley G. Clark, Charles F. Bauer, James B. Faulks, Joseph Bijur, H. L. Shippey, H. H. Harrison, C. D. Taylor, George Clapperton, Samuel Van Ronts, G. A. Robertson, J. E. Sleight, Otto Kartzmark, John W. Schroeder, O. A. Sandborgh, Albert Flammer, Charles Meyer, Fred Joerg, Adrian Chamberlain, F. W. Roebling. The society closed its year at this meeting with 607 members, of whom 215 have been elected during the year.

Convention Invitations.

The Chicago Edison Company has invited members and friends of the National Electric Light Association to visit its various stations for purposes of inspection, and the Electric Storage Battery Company has also issued a special invitation to an inspection of the large storage battery that has been installed for the Edison company in the Edison building on Adams street. Without doubt, these courtesies will be largely availed of during the present week.

NEWS AND NOTES

A Fatal Accident on the Hartford Third Rail System.

The first fatal accident from the effects of the third rail took place Thursday evening, May 26, when Harry Ray, 21 years of age, was killed in the rear of his home in West Hartford.

He walked down the tracks to the rear of his home, and in crossing the rails he either stumbled or stepped on the electric rail and fell from the effects of the shock. On account of the heavy rains, everything tended to increase the flow of the current through his body. Ray struck the rail on the back of his neck and was badly burned.

Some persons have escaped with burns and a number of animals have been killed, but this is the first fatality.

Short Distance Alternating Transmission, Fitchburg, Mass.

A good example of the use of alternating current for short distance transmission ease of starting the motors from a distance, reversing the same, etc., is to be found in apparatus now being supplied for the Fitchburg (Mass.) grain elevators by the Westinghouse Electric and Manufacturing Company. This consists of one 125 k. w. two-phase generator, seven 20 h. p. and two 30 h. p. Westinghouse type C motors, to be used in operating carriers in elevators. The induction motor is especially adapted for work in dusty locations, such as the above, where the use of direct current motors would be out of the question.

ROENTGEN RAYS

Roentgen Rays in War.

The first report of the use of the Röntgen rays in warfare has been made at the United Service Institution, in London, by Surgeon Beevor, who described the results of their use in the recent frontier campaign in India and gave lantern views. Many important cases consisted of bullet wounds received by officers and men who were injured in the bones, joints, and internal organs. Their injuries but for the X-rays would have resulted in the amputation of limbs and probable loss of life. The pictures shown included wounds in the arm, leg, chest, back, finger, and other parts. The most remarkable results, perhaps, were a case of a bullet embedded in the backbone, another in the hip, and the case of an Indian soldier who was shot in the foot, pieces of the bullet finally lodging in the back of the heel; also the case of Gen. Woodhouse, who received bullet wounds in the leg and arm at Dargai.

In all the instances enumerated the bullets were by the use of the X-rays successfully removed, the men subsequently rejoining their comrades at the front. The portable apparatus weighs 80 to 100 pounds.

REPORTS OF COMPANIES

Hartford, Conn. Electric Light Plant,

The board of directors of the Hartford Electric Light Company has voted to increase the capital of the company by the addition of $100,000 to the present capital of $400,000, which increases it to the limit allowed by the State Legislature.

The increase is to be offered to the stockholders on the basis of one share to every four now held, and the payments will be called for at the rate of 50 per cent. on July 5 and the remaining 50 per cent. on October 5. The books will be open June 15. During the year the plant has been entirely remodeled and the work will probably be perfected by January 1.

The big storage battery building on State street has been remodeled and is nearly completed.

A new steel and iron roof has been put in place, and a solid brick wall has been built between the battery room and the dynamo room. Everything is as nearly fireproof as is possible to make it. The business now done by the company is increasing steadily. At present the company is running over 36,000 incandescent and between 1,400 and 1,500 arc lights.

THE STOCK MARKET

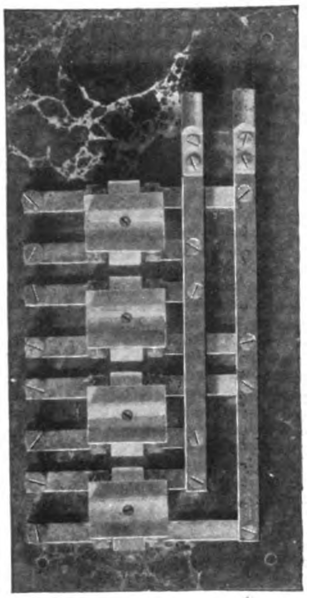
Crops and the State of Business.

Trade is generally good, quiet in some departments and brisk in others; on the whole, reports are cheerful with a strong tone. Agricultural conditions are most encouraging, and the wheat prospects are said to indicate a very large crop. May bank clearings were very heavy, showing a gain of seven per cent. over April, and of 28 per cent. over last May, 1897. Retail trade, checked by the wretched weather of May is good everywhere now.

The stock market has been very active, with a marked upward tendency, taking for granted the final defeat and wiping out of Spain. Railroads are doing well and paying higher dividends. Government bonds are higher, the new 4s going to 123. Western Union closed on Friday at 91⅝, General Electric closed at 36½, American Bell Telephone closed at 277, a gain for the week of 11 points. In Boston, copper stocks are higher. Copper is quoted at 12 cents, and heavy steel rail, Eastern mill, at $18.

TRADE NOTES & NOVELTIES

Zimdars & Hunt Specialties.



A NEW catalogue has just been issued by Zimdars & Hunt, 127 Fifth avenue, New York, (known as Cat. B.) dealing exclusively with panel, feeder and distribution boards. This is the first catalogue to appear covering completely this line, and its value to the trade, contractors and engineers especially, cannot be underestimated. While innumerable catalogues covering about everything else used in installation work have appeared, up to this time no catalogue dealing in a comprehensive manner with these articles has been available. The reason for this is probably to be found in the fact that the use of panel and feeder boards instead of the old porcelain cut-outs is of comparatively recent origin. The manner in which this matter has been taken up and handled in this catalogue reflects great credit on the firm. In looking over this catalogue, we find illustrated and listed in a systematic manner about all the types of panel and feeder boards anyone could have use for. Besides all those general types which from their extended use have now come to be looked upon as standards, we find many new and desirable types which should find a ready field. The matter throughout the catalogue is arranged in a very clear and comprehensive manner, complete prices and catalogue numbers being given in such a way that the possibility of mistakes occurring in referring to them is obviated.

Dimensions are given of all boards listed, and this feature will prove of incalculable value to the contractor who has been compelled heretofore to guess at the probable sizes of the boards he contemplated using.

The catalogue is very finely illustrated, the half-tone illustrations showing clearly all the distinctive features of the various types.

The cover, like that of this firm's catalogues A and C, is an exact imitation of marble, with copper embossing, and is a work of art.

This catalogue should prove a valuable acquisition to supply houses, contractors, and engineers, and can be obtained by addressing the above firm.

Sales of Walker Co.'s Apparatus.

Among the recent orders received by the Walker Company may be mentioned the following: One 250 k. w. belted railway generator and four double 4-A-S-1,000 railway equipments, for the Holland (Mich.) & Lake Michigan Railway Co. One 50 k. w. direct connected lighting generator for Russell & Co., Pittsburg, Pa., to be shipped to Sewickly, Pa. One 250 k. w. belted generator for Norton & Taunton (Mass.) Street Railway Co. One 30 k. w. direct connected generator by S. M. Fischer, Chicago, for the Patton Motor Co., same place. One 30 k. w. generator for W. A. Johnson Electric Co., Toronto. One 200 k. w. direct connected generator for Lewiston Electric Light Co., Lewiston, Idaho. Two 225 k. w. belted railway generators for the Wheeling & Elm Grove Electric Railway Co., Wheeling, W. Va.

The United States Ordnance Department has taken six 10-inch disappearing gun carriages for coast fortifications. The following orders for foreign shipment have been received: Edgar C. Moxham & Co., New York City, for Manaos Railway Co., Brazil, three 130 k. w. direct connected railway generators. Through agents in Japan, Messrs. Bagnall & Hilles, Yokohama, one 75 k. w. railway generator and switchboard apparatus and two double railway motor equipments, of 3-S-800 motors. Through London agency: Fifteen double equipments of 33-S-800 motors and type SL controllers. Two 120 k. w. railway generators with switchboard apparatus. Five double railway motor equipments of 3-N-800 motors.

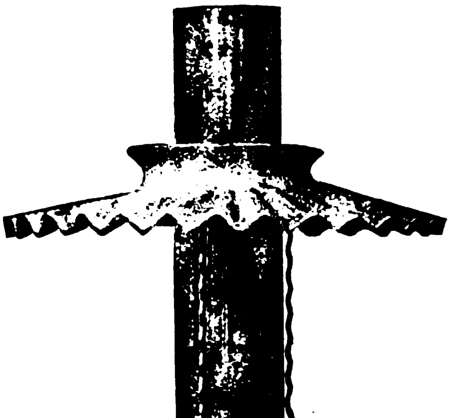
Thomas & Betts.

Robert McKean Thomas, E.E., and Hobart D. Betts, E.E., have organized a partnership under the firm name of Thomas & Betts, and have opened well equipped offices at the new Washington Life Building, corner of Liberty street and Broadway. The concern will act as agents for various well known electrical specialties, including the new "loricated" iron pipe interior conduit. They also carry on a general contracting and consulting business. Both gentlemen bring with them a large and varied experience. Mr. Thomas was for over two years assistant chief inspector of the New York Fire Department Electrical Inspection Bureau, and Mr. Betts has been an active member of the Edison Illuminating Company's staff.

Electric Gas Lighting Attachment for Incandescent Burners.

To use an old and threadbare phrase, there has been, since their introduction, a "crying demand" for a practical and low-priced method of lighting incandescent burners by electricity. This demand has been created by the inconvenience of lighting this burner when it is used on high chandeliers, and in the chain-pull style by the great danger of breaking mantles from the jar created in operating same.

To meet this demand an attachment has been designed which



ELECTRIC GAS LIGHTING ATTACHMENT FOR INCANDESCENT BURNERS.

embodies the improvements found in the "Advance" electric gas lighting burner. Among them are the smooth, easy action in lighting, which will not break the mantle; its operation is by key, in the same manner as the ordinary gas cock, and the fact that there is no possibility of the burner becoming short circuited in extinguishing. An additional feature is an adjustment in the pilot tube, by which the size and height of the pilot frame can be regulated. This obviates the blackening of the mantle, frequently found in burners lit from a pilot tube where too large a flame issues from same. The attachment can be used with the genuine Welsbach (as shown in illustration) and a majority of

the other incandescent burners now on the market. It is said to require but a few moments to attach. Stems are furnished in any length, but are sent four inches long unless otherwise specified.

The Electric Gas Lighting Company, 192 Devonshire street, Boston, Mass., are the manufacturers of this device, which is meeting with a ready sale. Descriptive circulars will be mailed upon application.

Fort Wayne Electric Corporation.

One of the interesting features of the electric lighting at St. Louis, Mo., as illustrated in our pages this week, is the large number of Fort Wayne wood arc dynamos in the plant, as illustrated in the engravings. The Fort Wayne Corporation remains still active and prominent in the arc lighting field where it has been so long and so favorably known. This fact is brought out and emphasized by the announcement made in our advertising pages, where the corporation show their beautiful No. 9 A machine with its new, improved regulator. The new No. 9 B 125 lighter is of the same type as the 9 A, with the new and improved regulator. The qualities of this apparatus are such as to commend it strongly to the favor of all engaged in the work of arc lighting, and there is no doubt that it will be as largely employed as that which has hitherto been everywhere recognized as highest grade and standard.

Bryant Electric Co.

The Bryant Electric Company, of Bridgeport, Conn., are erecting a new two-story power house 50 feet square. The building has brick side walls, and the framework is of steel skeleton type. The floor of the building is supported on heavy girders and columns, which carry steel joists supporting corrugated iron arches and concrete floor. The roof has clear span trusses carrying corrugated iron covering, lined with patent anti-condensation roof lining, which prevents the condensation of moisture on the underside of the roof covering, and avoids any damage or inconvenience from moisture dropping on the delicate machinery or material on the floor below. This building was designed and the steel material furnished and erected by the Berlin Iron Bridge Company, of East Berlin, Conn. The Bryant Company is increasing all its facilities for a large output.

Activity of the Central Electric Co.

In addition to their usually complete line of fan motors operative upon electric light circuits, the Central Electric Company, of Chicago, in order to meet the gradually increasing demand, have placed in stock a very complete line of fan motors operative from storage and primary battery circuits, prominence being given to the Edison-Lalande battery fan outfits. There is many a place and many a time when these atmospheric alleviators prove very serviceable. In a sick room they serve to keep a gentle circulation of the air that is exceedingly refreshing to a patient. Special circulars will be sent on application.

The Central Electric Company announce that they have taken the agency for the products of the Varley Duplex Magnet Company, of New York, manufacturers of magnets of every description, and will carry in Chicago stock all styles of standard coils for telephone construction. Special designs will be furnished on application.

Developments at Niagara.

The Carborundum Company, of Niagara Falls, are about to make a distinct departure in a business way from their present interests. They will erect a brick building three stories high, 50 feet wide by 228 feet long adjoining their factory on the Niagara Falls Power Company's lands in which carborundum will be spread on cloth and paper, and possibly leather. This step will place carborundum in direct competition with the emery, garnet and flint cloth manufacturers of the United States, of whom there are seven or eight. It will open up a branch of business which no doubt is destined to grow until the volume exceeds their present business in carborundum wheels, etc. The growth of the business will probably result in additions to the carborundum producing plant, steps to enlarge which are understood to be in progress.

The Mathieson Alkali Works, at Niagara Falls, are to be materially enlarged. This plant now consumes 2,000 electrical horse power. It is located on the lands of the Niagara Falls Power Company, its buildings covering more space than any other factory at the Falls. Additions are to be built until 6,000 electrical horse power are consumed. Manager B. F. Thurston is now at work considering the plans, and it is expected that work on the new buildings will begin within 60 days. This company have works in Saltville, Va., and offices in New York and Providence, R. I. They have found the use of the constant electrical power of Niagara so beneficial that they gladly avail themselves of more of it.

The Shelby Electric Company.

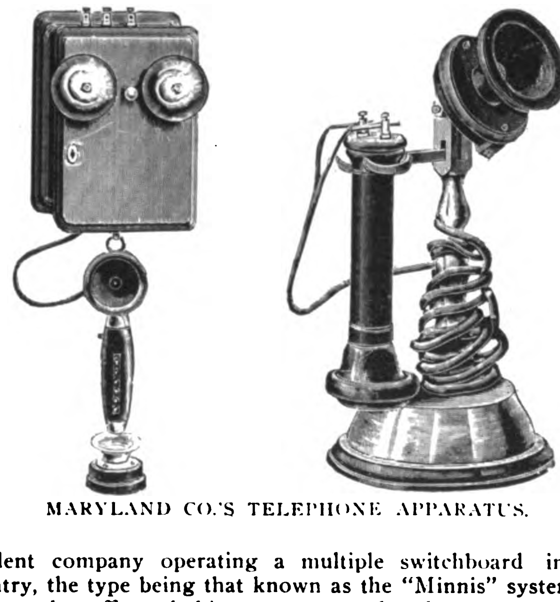
Owing to the increased volume of business the Shelby Electric Company, of Shelby, O., are now erecting an additional building adjoining the present factory. The new building is of brick, 34 by 80 feet, and three stories high. This addition will enable the Shelby Electric Company in doubling the present output of their well known Shelby lamp.

Sales of Onondaga Dynamos and Motors.

The Onondaga Dynamo Company, through their New York agents, Fairchild & Sumner, report the following recent sales: 190 h. p. in motors to the Atlas Cement Company, Northampton, Pa.; National Hat Company, Newark, N. J., 30 k. w. generator for lighting and heating; in the future the National Hat Company will do their flat-iron work by electricity; 5 h. p. motor, American News Company, Newark, N. J.; 10 h. p. motor to William T. Jancobius, electric carpet cleaning works, Newark, N. J.; 10 h. p. slow speed reversible elevator motor for the Causse Manufacturing Company, Jersey City, N. J.; 15 h. p. slow speed ceiling motor, the American Soda Fountain Company, Boston, Mass.; one 250 light lighting plant to Pass & Co., Wallabout street, Brooklyn, N. Y.; one 10 k. w. gas engine generators, with complete installation, for the Brown & Van Anglen Company, Newark, N. J.; 60 k. w. generator to the Paterson Silk Mills, Paterson, N. J. They also report their second installation of the special 60-volt exciter generator, direct connected, for the New York and Staten Island Electric Company, Livingston, S. I.

Maryland Telephone Mfg. Co.

The Maryland Telephone Mfg. Co. has been organized at Baltimore, Md., and has established a factory at 11 and 13 East Lee street, that city, under the general superintendence of Mr. C. B. Clark, formerly the electrician of the Home Telephone Company, of Mobile, Ala., which is said to be the only independent company operating a multiple switchboard in this country, the type being that known as the "Minnis" system.



MARYLAND CO.'S TELEPHONE APPARATUS.

The sales office of this company, under the management of Mr. Paul Minnis, the well known electrical engineer and telephone inventor, has been located at 130 Fulton street, this city, where may be found a complete line of up-to-date samples of the various types of telephones manufactured by the Maryland

company. This company is making features of the Brown loud-speaking transmitter and the Minnis system of telephones and switchboards; the latter being covered and protected by nearly a score of patents. The company is in the market for all kinds of exchange orders as well as orders for interior and intercommunicating sets, extension bells, desk sets, etc.

The officers of the Maryland Telephone Mfg. Co. are: M. Meyerdirck, president; H. H. Hebelman, vice-president; H. Knollenberg, secretary.

Four Hundred Pioneer Lamps Ordered.

Kaufman Brothers, of Pittsburg, have placed an order for over 400 Pioneer enclosed arcs for their new building with the Electric Arc Light Co., of New York. A unique feature of this installation will be the complete lighting of the store with arcs, and combination electric and gas chandeliers. This is the first store in the country to be entirely equipped in this manner. The Pioneer lamp was selected after a three months' competitive test.

WESTERN NOTES

WARREN ELECTRIC AND SPECIALTY COMPANY, Warren, Ohio, advise us that they are receiving a large number of suggestions of names for their new lamp, and as each suggestion must be accompanied with an order they are correspondingly busy. Some suggestions are of a character to provoke mirth and will be published after the contest is closed and prizes are awarded.

D. L. BATES & BRO., Dayton, O., report an excellent fan business this season. Their orders for the past month are fully 50 per cent. above the corresponding record last year. They report a phenomenal success with their alternating current ceiling fans. They are not only experiencing a brisk demand from the home trade, but are making large shipments to a number of foreign countries.

NEW YORK NOTES

MR. W. O. TURNER, who has for the past few years been connected with the Anchor Electric Co., of Boston, has resigned his position with that company and will now represent C. S. Knowles, of Boston, in place of Mr. A. T. Bell, who has become connected with the American Hard Rubber Co.

MR. R. J. RANDOLPH, who has for some years represented the Excelsior Electric Co. in Chicago, has come East and has accepted a position as general manager of the sales department of the Sterling Arc Lamp Co., of 214 West 26th street, New York City. Mr. Randolph is one of the old timers in the electrical business, having started with the late C. J. Van Depoele, in 1878, and he has been actively engaged in it ever since. He has a very wide circle of friends and will prove a valuable acquisition to the Sterling Co.

THE JEWELL BELTING CO., of Hartford, Conn., have opened an office at 1306 Washington Life Building, New York, which will be under the management of Mr. Edward C. Talcott, who brings with him a valuable experience gained by actual work in every department of the company's business. Mr. Talcott will be assisted by Mr. Ainsworth who has represented the Jewell Co. for some years in the Metropolitan district.

ADVERTISERS' HINTS

THE DEARBORN DRUG & CHEMICAL CO., Chicago, Ill., publish an unsolicited testimonial regarding the improved conditions resulting from the use of their boiler compound.

THE WESTINGHOUSE ELECTRIC & MFG. CO., Pittsburg, Pa., refer to some of the enormous contracts they have taken for alternating current generators.

THE EDDY ELECTRIC MFG. CO., Windsor, Conn., cite the advantages of the design of their motors and generators.

THE OKONITE CO., Ltd., 253 Broadway, New York, claim to be the largest contractors to the U. S. Government for submarine cables.

THEO. AUDEL & CO., 63 Fifth avenue, New York, advertise "Hawkins' Instructions for the Boiler Room," a book of considerable value to engineers, at $2.00.

THE ELECTRIC STORAGE BATTERY CO., Philadelphia, Pa., present a list of typical central station installations of chloride accumulators. It is a long one and bespeaks volumes for their efficiency.

THE PORTABLE ELECTRIC LIGHT CO., Chicago, Ill., advertise the "Marquette" headlight. It includes a dry battery for which they claim great things.

THE HART & HEGEMAN MFG. CO., Hartford, Conn., say that like a royal heart flush, their Hart flush switch is impossible to beat.

THE TRIUMPH ELECTRIC CO., Cincinnati, Ohio, call attention to the details of construction of their dynamos and motors.

A MODEL SWITCHBOARD is the title of the Wagner Electric Mfg. Co.'s "ad" and in it they illustrate one they built for the Missouri Edison Co., of St. Louis, whose plant is described at length in this issue.

THE DETROIT COPPER AND BRASS ROLLING MILLS, Detroit, Mich., are manufacturers of bore copper wire, sheet copper, brass, bronze and German silver, brass wire and rod, brazed tubing, rivets, etc.

ELECTRIC LIGHTING

General Distribution From Central Stations by Alternating Currents.[1]

BY HERBERT A. WAGNER.

EVER since the installation of the first few pioneer alternating-current central stations, just 10 years ago, we have heard it predicted with persistent reiteration that for the distribution of current for lighting from central stations direct current was a thing of the past, and that in a few years the alternating-current transformer system would hold the field without a competitor.

To many, this prediction may seem to have been fulfilled, considering the enormous number of alternating-current plants, compared with direct current, that have been installed, and the remarkable impetus given to electrical industries by the development of alternating currents.

The great success achieved in the transmission of power by polyphase alternating currents in the last three years has but strengthened this general belief, and left fewer champions to adhere to the direct-current cause.

These great achievements, I say, have led the enthusiast to think all progress confined to alternating systems of distribution. Deeper investigation, however, shows that while in point of number the alternating-current stations, reaching into the thousands, completely overshadow those of direct-current, there are few really large stations, outside of water-power plants, that are to-day employing alternating currents for distribution, and

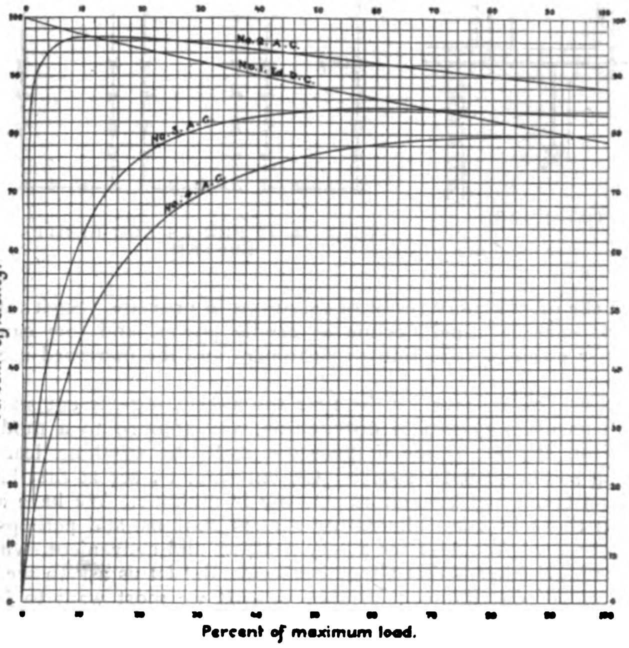

FIG. 1.—CURVES OF DISTRIBUTION EFFICIENCY.

that while enormous investments have been made in direct-current stations in our larger cities, comparatively small amounts have been invested in alternating-current work.

The alternating system was heralded as providing a means of distribution with a great reduction in first cost of plant, and for years the development of the system has been made with this the principal end in view. On the other hand, direct-current distribution in the form of the Edison three-wire system has been steadily and intelligently developed to the highest standard of economy of operation, simplicity and permanence. In the same city, alternating-current stations have not, as a rule, been successful in competition with three-wire stations; their service has not been as good, and their profits have been smaller.

I may startle many by stating frankly the discouraging fact, which has been barely whispered at times, that, judged by the standards of the magnificent Edison properties in many of our larger cities, few alternating-current central stations in the United States have been a success. Do not imagine that this damaging admission, however, is an indication of any loss of faith on the part of one who has been identified with alternating-current work since its début, as it were. Far from it. The fault lies, not with the alternating current itself, but with its application. Its few apparently inherent deficiencies, such as the difficulties of operating motors and arc lamps, have been shown to have been only awaiting discovery and development, and were at our disposal almost as soon as these important divisions of central-station service were operated with success from the Edison three-wire system. These can, therefore, hardly be held responsible for the difference in the commercial results obtained with the two systems.

As I have said, the ends in view in the development of the two systems have been radically different. The one was to produce a given amount of light for the minimum of investment; the other was to provide a permanent investment that would render the maximum of profit. These standpoints in general mark the difference between the manufacturer and the user, and we find these two systems developed in this way—one almost entirely by the manufacturer, and the other by the combined efforts of the various users. The results are the natural effects of progression along these lines.

Few opportunities have we had of comparing the two systems from the same standpoint and under like conditions. The purpose of this paper is to show the alternating current applied from the same standpoint, compelled to fulfil the same conditions, and then to compare the results with the best produced with direct current.

To better contrast the different methods of distribution, we will review briefly those in general use before describing the most recent developments.

The early alternating-current stations were installed on the principle that the drop in lines with distribution at 1,000 volts was so small that it was practically negligible. Two wires were accordingly run out from the station, passing along those streets where light was to be furnished, and lights were connected ad libitum at any desired points between the station and the farthest end, without reference to such trifling considerations as difference in potential. Distribution was attempted in this way for years, and in many places is still in operation. Lines are even being constructed to-day without any notion of a system of feeders and mains, although an almost perfect system for the maintenance of uniform pressure was in operation in many Edison stations before the first alternating station was in existence. Fortunately for the operators of such models of simplicity, the current delivered has usually been so small in quantity that with the proverbial No. 6 wire, which seemed to posses virtues not affected by distances, the difference of pressure between neighboring customers rarely exceeded 10 per cent.

A few more enlightened experts—plants were always installed by experts in the early days—eventually conceived the novel idea that if the drop, a little of which they had discovered by that time, could be confined to a greater extent to those portions of the lines where there were no lights, some might be spared from the lighting districts. A few feeder lines were therefore stuck in here and there to boost up the pressure where it was lowest.

The regulation was all effected by means of the dynamo field rheostat, and the pressure indicated by a voltmeter on the secondary of a transformer whose primary was connected to the bus-bars on the switchboard. A few lamps were also operated by the same transformer to light the switchboard or other parts of the station. The station attendant was, of course, in absolute ignorance of the pressure at any point on the lines where lamps were used. The pressure was therefore usually run high enough to be on the safe side. The attendant was sometimes instructed to let his voltmeter needle follow gently the maneuvers of his ammeter, as there was thought to be a more or less intimate

[1] A paper read before the Nat. Elec. Light Ass'n, Chicago, June, 1898.

connection between volts and amperes and the volts ought not to be allowed to get too far behind.

If anyone ever breathed a suggestion of pressure wires, it was probably his last breath. At any rate, he was never heard of again. What! pressure wires with alternating current? Preposterous idea! Alternating and progression were considered almost synonymous terms. Antiquated ideas must be abandoned.

This faintly-whispered need might, however, be heard again, so, to meet the emergency, a compensating voltmeter was produced that could be adjusted for any drop in the lines. It was ingeniously arranged so that a small series transformer in the main line would send currents opposing those operating the voltmeter, thereby making the needle or index drop back approximately proportionately to the current in the line. This device was a great help, and caused the drop in lines to jump into prominence at once. It would be quite perfect if the drop in alternating-current lines were proportional to the current, but it is not. The power factor of ordinary alternating-current systems is usually quite low at light loads, and, except with very small wire, an ampere may therefore produce much more drop proportionately at light load than at heavy load.

One alternating-current station of which I have intimate knowledge has used pressure wires in connection with each feeder for years. There may be a few others, but they are rare exceptions even to-day.

ing for these transformer stations, together with the investment in instruments and switches required, and the attendants' wages, there is very much saving effected. Had we nothing better to turn to than these systems, the cost of distribution from large stations would be extreme compared with the direct-current, Edison three-wire system, and competition with the latter could not be a success.

Another very important consideration is the economy or efficiency of lamps used. To employ successfully the highest-economy lamp made, a very uniform pressure must be maintained. With the usual alternating-current system, and with an equally good disposition of feeders and mains, the variations of pressure will exceed those in a direct-current system by nearly 3 per cent., on account of the transformer drop, and to secure even this limit of variation, pressure wires must be used with each feeder.

It is not surprising to find, therefore, that almost all alternating-current stations are using lamps requiring 20 per cent. more current than those used by direct-current stations.

I cannot refrain from remarking here that to operate any station, alternating or direct-current, without pressure wires, is to be worse than penny-wise and pound-foolish. In any alternating-current station employing overhead wires, the saving in lamp renewals would equal the cost of pressure wires in little over a month's time. I might also add that the total loss of lamps is

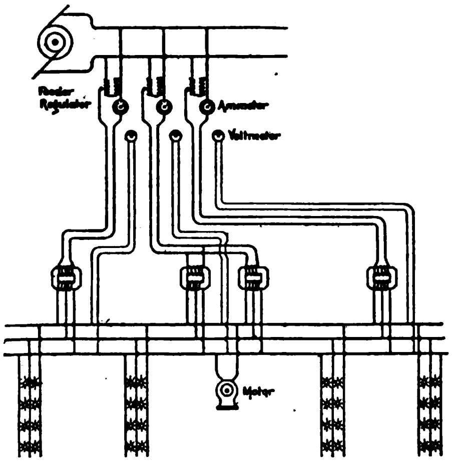

FIG. 2.—SINGLE PHASE A. C. SYSTEM.
With high pressure feeders and low pressure distribution. Independent feeder for each transformer or group.

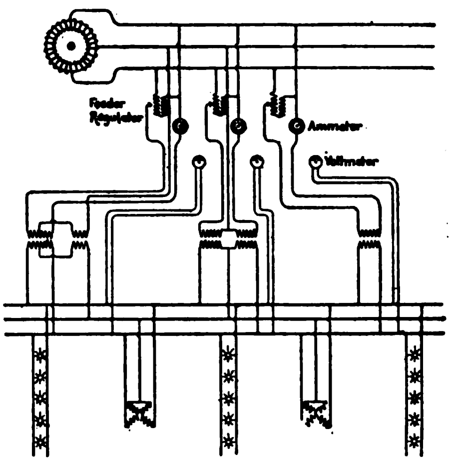

FIG. 3.—THREE-WIRE TWO-PHASE SYSTEM.
With single phase lighting. High pressure feeders and low pressure distribution.

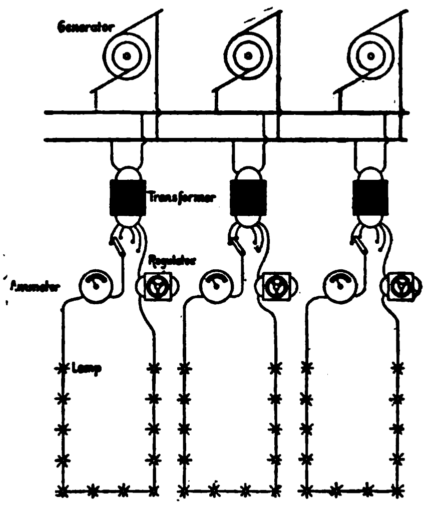

FIG. 4.—A. C. SERIES ARC LIGHT SYSTEM.

The usual system of distribution provides a separate transformer for each customer. In many cases, this implies the use of a very small transformer. It is impossible to make the efficiency of small transformers high. As each customer may at times use all of his lamps, he must have full transformer capacity for such an emergency. The ordinary ratio between maximum station loads and the number of lamps connected, is in most cases under 50 per cent. where meters are employed. The transformers then being of a total capacity equal to the number of lamps connected, average at best only 50 per cent. of their rated capacity at the maximum station load. In most stations the average load generated is much less than 25 per cent. of the maximum load, and, therefore, with twice the transformer capacity of that represented by maximum station load, the average transformer load would not exceed 10 per cent. of the transformer capacity, all the year round.

The efficiency of the average modern transformer of usual size at 10 per cent. of its rated load is not over 65 per cent., and the average of transformers at present in use not more than 50 per cent. It is perfectly safe to say that there is not an alternating-current station to-day using individual transformers for each or neighboring customers that can show an average efficiency of distribution of over 60 per cent., and few that can show over 50 per cent.

In Europe, it is, to some extent, the practice to use transformer sub-stations with low-potential distribution from these points. Transformers are cut in and out at these sub-stations by attendants according to the demand for current. It is doubtful if, after paying interest on the investment in property and hous-

not the most serious result of variations in pressure. Such variations cause a rapid decline in candle power, and low candle power means disaffection of customers and the increased use of gas.

Now, let us leave for the time the alternating-current station and its usual system of distribution, and adjourn to a modern Edison station, to see if there can really be anything learned from so antiquated a source. On entering, we see at first large direct-connected generators running in multiple. We have also seen those in a few alternating-current stations, and perhaps of larger size. We next see a very compact and convenient switchboard. Neither is that altogether new. But let us ask to see the system of distribution; for that is what we most want to look into.

On the plans of this system of distribution a remarkable network of feeders and mains is laid before us, most carefully calculated for the maintenance of uniform pressure. Means for regulating more or less independently the pressure on each feeder are provided. From numerous points in the system, corresponding to the feeder terminals, pressure wires are brought to the station, and indicators show the pressure at all these points. Numerous devices and appliances are shown us which must have been the result of years of experience in the development of distribution methods. We look with admiration, and ask why, with this apparently far more perfect system in existence, have we been working so long to try to perfect a new system that cannot to-day, we are informed, produce such results. Why, indeed!

But let us look a little further. What are those massive

beams? They do not seem to support anything. "Those are not beams. They are copper wires to carry the current out," we are told. "Wires? Why, they weigh tons!" "So they do, but they are necessary with this system." A very serious drawback, it would seem. Another question troubles us. Why do you occupy ground in a part of the city where property must be very valuable? Why do you not go off to one side where land is cheap? "Oh, we are forced to be near our centre of business. If we were twice as far away we should have to use four times the amount of copper in those bars." This, indeed, seems a very great defect. But are there no other defects in your system? In answer, we are told that there are no others that are considered serious.

If this necessity for using such an enormous amount of copper is the weak point of a beautifully developed system, why do we not endeavor to overcome that particular point and adopt the rest, instead of starting out anew and alone to develop another system from beginning to end? This is the question that should have been considered years ago. Why did we not start where others left off, engraft our alternating current and draw energy and strength from the old roots, instead of trying to grow from the seed to find ourselves running to limbs and branches with very little trunk to speak of. We have tried to overreach our older brother, and now lack his sturdiness and stability.

It is not too late, however, to begin afresh. We are satisfied that at the present time the Edison three-wire system of distribution is the most efficient in use and the most nearly perfect in details. We know that the usual system employed with alternating current is not efficient, and does not admit of as close regulation, but it is vastly cheaper to install.

Comparing the cost of individual transformers and high-potential distributing mains with the three-wire system of mains at low potential, we do not find a great difference in first cost in favor of the alternating. We do find, however, that the Edison feeders for the same distance cost about thirty-one times as much as for alternating current at 1,100 volts, 125 times as much at 2,200 volts, or 500 times as much at 4,400 volts. It would then appear that if we could apply alternating current to the feeders at high potential and transform down for the mains, we might reach the lower first cost of the ordinary alternating-current system and possibly retain all the best features of the direct current. To accomplish the former, the transformers must be provided at a small proportion of the cost of the alternating-current feeder, and to do the latter, they must not increase the average losses in the system. It is obvious that we could with alternating current move our station to any reasonable distance from our centre of distribution and at comparatively small additional cost for feeders. The whole problem then seems to come down to transformer efficiency and means of regulation.

To consider the matter of regulation first. We see at a glance that we cannot use the direct-current method of regulation by supplementary bus-bars, but we can use the booster method, and can, moreover, apply a static booster to each feeder to regulate within any desired limits and with as small gradations as necessary. In fact, the booster method of regulation was first applied to alternating-current distribution, and operates with much less average consumption of energy than either the supplementary 'bus or direct-current booster method. In this important consideration, we can therefore improve on and simplify direct-current methods.

The means of regulation having been in this way provided for the feeders, it remains to be considered what we shall do to eliminate the effects of transformer drop. As we have determined on a secondary low-potential, three-wire distributing system of mains, we can altogether dispense with high-potential mains and limit the high potential to the feeders. If we do this, we can conveniently have the transformers of the same unit capacity as the feeders, and arrange each with its primary connected to its independent feeder and its secondary feeding into the three-wire mains. We know that the effects of our feeder drop are eliminated if we regulate by pressure wires from the feeder ends. In the same way the effect of our transformer drop may be eliminated by bringing pressure wires from the secondary terminals. The feeder drop and transformer drop therefore become one, and are cared for in the same way. We can even secure better general regulation than with the direct-current system, as we have a better form of feeder regulator and have eliminated the effects of transformer drop.

Now, to return to the transformer itself and its efficiency. It is evident that, with this system, the transformer capacity need be no greater than that required for maximum station load, instead of more than twice that amount or nearly equal to that required for the total number of lamps connected. This at once doubles the average load on our transformers, and raises the average efficiency. It also incidentally reduces the first cost of transformers in still greater proportion. We also know, however, that transformer efficiency at light loads is dependent on the iron loss, and that this is interdependent with the regulation or drop. If we can increase the drop, we can decrease the iron loss, and thereby greatly increase the average efficiency. Having provided against any interference with the regulation of the system by the transformer drop, we can afford to increase that to the heating limit of the copper. In this way, a 100-kilowatt transformer can be built with an average efficiency of over 98 per cent. The entire transformer loss can, moreover, be more than made up by the less loss in feeders, which we would naturally have with alternating current.

We have thus eliminated the two features in which the ordinary alternating-current system of distribution has been inferior to the direct-current, and have provided means for obtaining better regulation and higher efficiency at a very much less cost of installation than with the direct-current system.

This system was conceived several years ago, and it has since been my good fortune to have an opportunity to install a system of this kind on a large scale, which is now in very satisfactory operation. It is laid out exactly as a three-wire Edison system would be, except that there are no sub-feeders. A network of mains is planned as if for use with direct current. The feeders are all designed for 110-kilowatt maximum load at 1,100 volts, and at each feeder end is placed a 110-kilowatt transformer feeding into the three-wire network in the same manner and at the same points as with the direct-current system. The transformers are located in manholes of suitable design. From the secondary terminals of each transformer, pressure wires are run back to the station. Each feeder has an independent regulator by which the pressure can be raised or lowered. There are no primary mains, nor any connection whatever between the primary feeders. The regulators perform two functions. They are used to maintain the proper pressure as indicated by the voltmeters and also to divide the load between transformers in any way desired as indicated by the feeder ammeters. It is possible to shift the entire load from one transformer and feeder to an adjacent transformer in this way without sensibly affecting the pressure on the system, and an equal division of load between transformers can be readily maintained at all times if desired. This is a very important consideration when very heavy loads or overloads are to be carried. The distribution of load on any large system is constantly changing as new customers are connected, and in large Edison stations certain feeders often become so overloaded that it is found necessary for their safety to put resistance in series with them to force some of the current to other feeders. The possibility of overloading any individual feeder beyond its share is absolutely provided against in the system described. To make the arrangement of this system perfectly clear it is illustrated diagrammatically in Fig. 2.

In Fig. 1 are shown four curves of station distribution efficiency. No. 1 is that of a representative Edison three-wire, direct-current station. No. 2 is the new alternating-current system described. No. 3 is the usual alternating-current system employing separate transformers for each customer or for adjacent customers, the best modern transformers being used. No. 4 shows the same system, but with the average transformers found on the lines of most existing stations. These curves were plotted from the following data obtained from actual practice:

	No. 1. Per cent.	No. 2. Per cent.	No. 3. Per cent.	No. 4. Per cent.
Feeder loss	24	8	10	10
Main loss	2	2	2	2
House wiring loss	1	1	1	1
Transformer loss, iron		.23	6	12
Transformer loss, copper		2.7	1	.5
Total loss at maximum station load,	27	13.93	20	25.5
Efficiency at maximum station load,	78.7	87.9	83.3	79.6

The efficiencies of distribution at assumed average loads are shown to be as follows:

Per cent.	No. 1. Per cent.	No. 2. Per cent.	No. 3. Per cent.	No. 4. Per cent.
Load, 25	94.1	95.8	78.4	66.6
Load, 20	94.8	96.2	75.3	61.4
Load, 15	96.1	96.5	70.3	54.3
Load, 10	97.3	96.4	61.9	45.1

At maximum load it will be noticed that the efficiency of alternating-current No. 2 is 10 per cent. higher than No. 1, the direct current. This means that the same energy can be delivered with 10 per cent. less capacity in generators, engines and boilers, or a difference of 10 per cent. in the first cost of generating plant. It is pertinent to remark here that alternating-current generators also have a much greater margin for overload for short periods than direct-current generators. The efficiency at average load, or the all-day efficiency of the No. 2 alternating-current system is also shown to be appreciatively higher than the direct-current. In large central stations the average load is generally found in practice to vary from about 15 to 20 per cent. of the maximum, and it will be noted that from 12 per cent. average load up, No. 2 curve for the special system of alternating-current distribution shows a higher efficiency than the direct current.

It may be asked what effect the aging or fatigue of the transformer iron will have on these figures. I answer, none appreciable. Transformer manufacturers are willing to guarantee as low as 1 per cent. increase per year in iron loss. This means 1 per cent. of the actual amount of energy lost in the iron, so that, if this increase continued at the same rate, it would take 100 years to double the iron loss. Experiments tend to show, however, that this effect rapidly approaches a maximum and that therefore the increase goes on at a constantly decreasing rate. The entire effect may be eliminated, if desired, about once in five years by reannealing the transformer iron at a very small expense.

It has been the practice in some European stations to cut out transformers during periods of light load, but it will be seen that cutting out transformers in the system described would only decrease the efficiency; in fact, the efficiency is higher at about the average load, and the system was designed throughout to accomplish this result.

The less we say about curves Nos. 3 and 4 the better, as at small loads the efficiency is shown to be appallingly low.

EXTENSIONS OF DIRECT CURRENT SYSTEM BY ALTERNATING CURRENT.

Several large three-wire, direct-current Edison stations are beginning to employ alternating current to extend their lighting territory beyond that possible or profitable with low-tension current. This is a recognition of alternating current which would not have been considered for a moment a few years ago. They now propose to use alternating current to transmit their energy at high potential to a distant sub-station, where it will be transformed to a lower pressure and then again transformed by means of rotary transformers to direct current, which is in turn distributed over the three-wire Edison system as if generated in the ordinary way. This is a very beautiful and instructive application of alternating currents, and ingeniously designed machinery. It gives the manufacturers a chance to sell additional machinery, swells the company's real estate investment and gives work to the unemployed to operate the substations.

The loss is in the conversion to alternating current and back is about 15 per cent. in addition to the loss in static transformers and lines. This distribution might be accomplished without the additional machinery, wire, real estate, labor and loss in efficiency. It is hardly to be expected, however, that those who have grown up under the protection or influence of direct current would use alternating current any further than absolutely necessary until they have grown more accustomed to the new mode of travel. After looking across the stream to coveted territory for many years, they are willing to use the new bridge and to ride across at about the highest speed provided, but when they get on the other side they are more than satisfied to foot it again the rest of the way.

A much higher efficiency of distribution, and better regulation could be secured by using the alternating-current system as it is, without transformation to direct-current, and everything could be controlled from the main station without employing labor or apparatus at sub-stations. Why do they not use it so? They say that many things cannot be accomplished as well with alternating current. If that is a challenge, we will accept it and try conclusions with them. Let us then anticipate these various objections and see what they amount to.

FIRST, EFFICIENCY.

We have already seen how a properly designed system of distribution for alternating currents may be made to exceed the direct-current system in efficiency, taking the latter under its most favorable conditions. If we then add to the usual losses in the direct-current system the losses in double rotary transformation and in static transformers, the very great difference in favor of the alternating current is still more marked.

REGULATION.

It has been shown how very simple and reliable regulators can be provided for each alternating-current feeder, which will secure the closest possible regulation over any range desired, and this can be effected at a loss of less than 1 per cent. Such close regulation can only be secured with direct current by the use of a number of generators connected to auxiliary bus-bars, or by connecting the feeder ends to adjustable resistance connected between the 'busses of two or more generators. The first cannot be realized in a rotary-transformer station, and the last is quite wasteful of energy. Regulators placed on the alternating-current feeders of the rotary transformers control alike the pressure on each rotary, and all the direct-current feeders supplied by the same, in exactly the same way as field regulation does on a direct-current generator. Such regulation can only be effectual with a number of small rotaries not operated in multiple. The best regulation can, therefore, undoubtedly be secured with the alternating-current system.

OPERATION OF ARC LAMPS.

It seems now to be the universal opinion among Edison station men that the enclosed-arc, long-burning lamp is destined to replace all the old forms of arc lamp. We will, therefore, consider this type of lamp only. Fully as well-burning lamps of this type are now made for alternating current. They are also about as free from noise as the direct-current lamps. Many will say, however, that it is impossible to get as much light from the alternating current as from direct current. That is true if we state that the same energy in the arc produces less light with alternating current than with direct current. It has been determined that the alternating-current arc produces about 70 per cent. of the light to be obtained from the same number of watts in the direct-current arc. The usual direct-current enclosed arc requires 5 amperes at 115 volts, or 575 watts. How much of this is used in the arc? Somewhat less than 80 volts, or under 400 watts; the balance of over 175 watts being wasted in resistance.

With alternating current, 70 per cent. of the amount of light would be obtained with this 400 watts, or about 570 watts would be required to produce the same light. The alternating-current arc is best operated at about 70 volts, but inductive resistance is used to bring the pressure down to this amount. This inductive resistance consumes about 10 watts actual energy, making in all 580 watts, against 575 for the direct current for the same amount of light. This difference of 5 watts, or less than 1 per cent., is insignificant.

The standard alternating-current enclosed arc consumes about 420 watts at the lamp terminals, but I have had made to order a large number of 550-watt lamps, which have replaced many series 10-ampere direct-current lamps. There are certain kinds of arc lighting to which the alternating current is particularly well adapted, of which I will speak later on.

MOTORS.

The greatest argument used against alternating current used to be that it would not run a motor. It has long ago proved that it can, and that without a commutator. This subject now brings us to multiphase systems. There are two of these systems in general use, the two-phase and the three-phase. Other systems are but modifications of these and will be mentioned as such. Motors can be operated with equal facility and efficiency on either system and have many distinct advantages over direct-current motors.

For long-distance power transmission the three-phase system shows an economy in copper; but for lighting, or for lighting and power combined, it is not at all well suited. I might say that where lighting is a distinct feature, and first-class service is to be rendered from a large station, the three-phase system cannot be used successfully. On even the best generators the windings are so entirely independent that a change of load on one phase will affect the pressure on the other two; but a defect even worse is the impossibility of regulating the phases independently for drop in the feeders if the load happens to vary differently on any two. Any regulator placed in circuit with one phase will effect about the same change of pressure in the adjacent phase within the usual limits of regulation. Regulation

is then a question of the best possible averages, and at best is but guesswork. With the feeder and transformer drops found economical in practice, it would be practically impossible to keep the pressure sufficiently constant for high-efficiency lamps. The complication of wiring is also very serious, especially if the Edison three-wire system is used for distribution, as six wires would then be required, forming six circuits that must be kept balanced.

The two-phase system is subject to the same objections unless the two phases are used separately for lighting, in which case we have the complication equivalent to twice the number of generators and feeders.

For good regulation and simplicity, the single-phase system cannot be equaled by any multiphase system.

The so-called monocyclic system is a modified two-phase system in which current is distributed for lighting on a single-phase circuit only, and a third wire carries current in quadrature to the first, which, in connection with the first, is transformed to a three-phase relation wherever it is desired to operate motors. The regulation of this system can be made almost as good for lighting as the single-phase, and can be as simply affected. The third wire adds complication, but no balancing is required, as all the lighting is done from single phase on two wires. If low-tension, three-wire distribution is attempted with this system, a fourth wire must be used for power distribution.

A system practically the counterpart of the monocyclic is the three-wire, two-phase system, in which the lighting is all done on one single-phase, and a third wire is used in conjunction with the other two for power. It is handled in exactly the same manner as the monocyclic system, the only practical difference being in the relative potential of the quarter-phase circuit. In the monocyclic, the quarter-phase element of the generator winding is one-quarter the potential of the main winding, giving between the power line and the main lines a pressure of 55 per cent. of that between the main lines themselves. In the special form of three-wire, two-phase, the quarter-phase element of the generator winding is equivalent to one-half of the main winding, which causes a pressure between power line and main lines 71 per cent. of that between the main lines. For power distribution, this system requires slightly less wire than the monocyclic. Fig. 3 shows diagrammatically the arrangement of this system used in connection with the special method of distribution already described. The diagram shows a system of two-wire mains for lighting to which might be applied, of course, the Edison three-wire system. The motors used would most naturally be of the two-phase type, although three-phase motors may be used with equal facility by the method of transformer connections devised by Mr. Scott.

It can be readily seen that while these systems are much better adapted to general station distribution than the two-phase or three-phase, they will lack the simplicity of the single-phase, and both require more wire. Fortunately, we can now obtain single-phase motors which equal the multiphase and direct-current motors in efficiency and all most desirable points. They start readily with load and may be operated with variable speed; in fact, they equal the direct-current shunt motor in all points, excelling it in efficiency and simplicity.

We can meet the direct-current advocates on the power question, therefore, on at least an equal footing, save only one application met in central-station practice, namely, the operation of high-speed elevators. The alternating-current motor, multiphase or single-phase, cannot be controlled for this work as readily as a compound series, direct-current motor. It has taken several years, however, to perfect the mechanism for the control of direct-current elevator motors. Give us the same time and we will do it with alternating current. This field for power has only of late been opened to direct-current stations, and it is yet a question for debate as to whether it is a paying one.

SPECIAL APPLICATIONS OF CURRENT.

There are many special applications of current met with in practice, most of them bringing a small return, such as electroplating, electro-cautery, charging small storage batteries, electric heating and cooking, etc. The first three require low-potential currents and are economically effected only by motor generators or rotary transformers. It is evident that this transformation can be accomplished as readily with alternating current as with direct current. Electric heating and cooking are as yet luxuries and cannot be depended on for much revenue. They can be done with equal facility by alternating current.

STORAGE BATTERIES.

Here we come to the direct-current advocate's last and greatest stronghold. To this he retreats with great confidence of safety. We may ask first whether storage batteries have yet been proved to be a valuable adjunct to the central station, cost and maintenance considered. It is true they are being tried by several large stations, and we watch eagerly for the results. They equalize the station load to a greater or less degree, and cut down the generator capacity for the peak. Are they, however, cheaper than generators, engines and boilers of the same capacity? Are the losses in transformation less than the cost of a few more attendants? Is their maintenance less expensive than that of generating apparatus? These questions cannot as yet be answered in the affirmative. But if the battery man's most sanguine hopes be realized, what then? If rotary transformers are good enough for the direct-current man to use to change the direct current to alternating current, transmit a good proportion of his load to a distance and transform again to direct current, why should not the alternating-current man use them to charge his batteries and then to transform their output back to his pet form of current? Loss in transformation, do we hear some one say? Not any more than with our contemporaries' long-distance transmission system, and, in this instance, they are small and unimportant, we are told. There is at least one station in the country where storage batteries are being used in this way, and I believe with success, as storage batteries go.

Have our direct-current friends anything more to bring forward? Or have we forced their last position? Well, we will declare a truce, and acknowledge that they fight bravely. We have learned as much from them as they can learn from us. If we had been as quick to acknowledge their beautifully designed distributing details and applications as they have been to appreciate a few of the advantages of our current, we might have been nearer together, or even hand in hand, long ago. As it is, we are both working to the same end, and our paths must join sooner or later as they converge.

Before closing, I wish to recapitulate a little, and draw your attention more forcibly to the flexibility of the alternating-current system. We all know of the many applications to which this current is now put, and what we have described here is, most of it, not new to many of us. The use of the rotary transformer has been widely talked of and described for the last two years. The facility of operating lines at any potential desired, through the means of step-up and down transformers is no longer an experiment. Multiphase motors are familiar to all, while single-phase motors have been much talked of and written about, and failures have, time and again, followed boasted success. Many of us, however, have within the last year seen them quietly at work, thoroughly tamed and domesticated. One large station is using them extensively, and is so thoroughly convinced of their success that it has discarded all notion of using multiphase distribution, although it is using generators that can be operated two-phase if desired. Direct-current motors are being rapidly replaced by these single-phase motors to secure uniformity of system.

Arc lamps have been familiar to us on alternating-current circuits for some time, and the alternating current, enclosed, long-burning arcs are now numbered by the thousands. Street lighting is still, however, in most places done on the direct-current series system, and even the largest machines yet built for this purpose are very small in comparison with our large direct-connected generators.

The great desideratum in central-station practice is to be able to employ one system for everything. All current for all classes of service should be supplied from but one generator, be this direct current or alternating current. In this way, only, can the maximum output be accomplished from a given investment in machinery and apparatus, and the greatest economy in operation secured. This has been accomplished in many stations where a limited range of service is to be provided. Arc lighting has, of all, been the most troublesome to provide for. How shall we operate our arc lamps from our incandescent lighting system, has been the anxious inquiry. The constant-potential arc lamp has answered this question for commercial lighting, but city street lighting cannot be so easily provided for. The Edison companies have done a limited amount of this from their three-wire system, but this can be done to advantage only in districts where mains have been provided for commercial lighting.

For extended arc lighting, the small series machine with its belts and clutch pulleys still holds the fort.

I am able to state, however, that one large company has recently solved the problem to its entire satisfaction. This company furnishes 2,600 street lamps to the city, lighting some 300 miles of street. These were operated by a small army of series arc machines. They were installed by a company that was acquired by purchase by the one first mentioned. As this company had long since adopted alternating current for its entire distribution, it was extremely desirable to be able to operate these city lamps from its large direct-connected alternators, thereby saving in fuel, attendance, floor space and reserve investment.

After a few months' trial of an experimental circuit with alternating current, it was found perfectly feasible to operate the same direct-current lamps, slightly remodeled, on the same circuits of 60 or 80 lamps in series. A system of this kind was therefore adopted and the company now has 2,300 of these lamps in regular operation by alternating current in this way. The circuits are each provided at the station with a regular step-up transformer of a maximum capacity of 4,000 volts and 10 amperes, and the feeders to these transformers are treated on the switchboard in the same way as the feeders for incandescent lighting. It is quite usual for one generator to carry 2,000 of these lamps. The lighting is satisfactory to the city and the lamps give better service than when operated by direct current. There has been a very marked saving in fuel and attendance. The indicated horse-power per arc lamp is considerably less than with the direct-current arc lamps operated in the usual manner. Fig. 4 shows this system in diagram.

I know of no other place where this is being done, and it stands as a very pronounced example of the flexibility and adaptability of alternating currents.

There have been a great many problems in the operation of large alternating-current stations that have been discouragingly difficult of solution. The handling of high potentials on switchboards, the operation of generators in multiple, with facility, and scores of more or less important difficulties have, one by one, been surmounted, the burden of the work usually falling on a few of the pioneer stations.

In summing up, we find the following marked features in which the alternating current, properly installed, has been shown to have pronounced superiority over the direct current:

Highest possible efficiency of distribution and operation.

Best regulation.

Largest territory desired readily supplied from one station.

Comparatively small cost of feeders, effecting enormous saving in investment.

Least cost of real estate.

Cost of installing and operating sub-stations entirely void.

The only system in which all classes of service can be supplied from one type of generator.

Greatest flexibility.

In closing, I wish to thank my friends and co-laborers of the direct-current faith, from several of whom I have had the pleasure of learning much that has proved of great value to me.

Induction Motors in Bleach and Dye Works.

The Westinghouse induction motors (type "C") are everywhere demonstrating their usefulness in new fields. Some two years since, the Westinghouse Company installed for the Silver Spring Bleaching and Dyeing Co., of Providence, R. I., a complete plant for power purposes, and the growth of the business since that time has recently called for an equipment of fifteen type "C" induction motors of the latest type.

The conditions of service are very severe indeed, many of the motors operating continuously in clouds of steam or in the presence of chloride fumes which rapidly corrode all exposed copper parts. Some of these motors have to exert four times the normal torque in starting ironing machines or calendars full of heavy gearing, etc.

The installation, which was regarded as a risky experiment when first contemplated, has proven a most pronounced success.

DeVEAU & COMPANY have had an order from the Government for 57 submarine telephones for the use of divers.

Presidential Address; Chicago N. E. L. A. Convention.[1]

BY SAMUEL INSULL.

IN calling to order the annual convention of your Association my dual capacity presents somewhat of an embarrassment to me. I am in doubt whether as president to enlarge upon the great growth of this Association since its formation in this city on February 25, 1885, or whether as a resident here to dwell at length upon the marvelous growth of the city in which we meet. Chicago and the industry with which we are identified have a somewhat close connection. The growth of the former, if measured from the point of view of the rapidity with which history is made, is, so to speak, the product of yesterday. The electrical industry, or rather that portion of it with which we are associated, is but little more than the product of to-day. If the growth of this city and that of our own industry is as great during the next thirteen years as the progress that they have achieved since the date of your first meeting here, I am sure that both the citizens of Chicago and the members of your Association will have every reason to congratulate themselves. Speaking for those of my friends connected with the electrical industry in Chicago, and also for myself, I can assure you that it affords us very great pleasure to welcome you at this convention, and the fact of your meeting in this, my home city, enhances not a little my high appreciation of the privilege of presiding on this occasion.

The officers of your Association have had in mind in preparing a program for this convention the importance of bringing before you subjects of interest in connection with central station management, and the papers to be read at our various sessions and the topics mentioned for discussion cover such a wide range that it would seem undesirable for me to occupy much of your time by way of introduction. The various gentlemen who have so kindly consented to read papers will deal with such important questions as the cost of generating and distributing the product which we manufacture, transformer economy and the rival claims of alternating currents and direct currents as means of distribution. The many problems which you have to solve in connection with the question of public lighting and the cost of producing electrical energy by water power, will also be discussed.

STANDARD VS. SPECIAL MACHINERY.

A matter which has called forth during the last year considerable discussion is the question of the use of standard apparatus and the tendency towards the specification of special machinery on the part of electrical engineers. This course is not by any means confined to large work, but is followed by some engineers whether they are designing a small isolated plant or are projecting a large modern central station. It would seem to me to be of paramount importance to the manufacturer and user that both should co-operate in eliminating as far as possible from the business the necessity of building and using special types of machinery. This can only be done by the adoption of standard specifications for various standard types of apparatus. A committee of the American Institute of Electrical Engineers has already taken this subject under consideration, and I believe that we will be serving alike the interests of the manufacturers and users of electrical apparatus if we will take some action with a view to co-operating with the Institute and other bodies in this matter. In drawing attention to this subject I speak with an appreciation of the position of both manufacturer and user, having had more or less connection with the manufacture of electric apparatus and the manufacture of electric current. Constant duplication of parts resulting in constant duplication of a given piece of machinery means, as any manufacturer will tell you, constant reduction in cost. Variation from a given type means increased cost and even the wiping out of an apparent profit. In the last year or so there has been a great deal of discussion in England prompted by the success of American manufacturers in obtaining large contracts for electric traction work in Great Britain, and the inquiry has often been made, how is it possible for American electrical manufacturers, with high wages against them, to compete with English builders, whose scale of pay to their workmen is on a very much lower basis. If you will examine into the amount of electric traction machinery manufactured in this country under a system of constant duplication and

[1]Delivered before the Nat. Elec. Light Assoc., Chicago, June 7, 1898.

the use of special tools, and then visit the electrical establishments on the other side of the water and note the tendency there towards specializing each particular job, you will soon recognize that the reason for low cost and consequently low selling price on this side of the ocean, is brought about by the fact that in America this class of work is largely designed by the manufacturer, and as a natural result is the duplicate of something already produced, whilst on the other side of the Atlantic the builder of the machinery works from the plans of the electrical engineer, which necessitates his producing something different to fill each different contract. In one case the machinery is really manufactured; in the other case the builder runs a jobbing shop. Unfortunately during the last few years American users of electrical apparatus have somewhat departed from the pursuance of what is really a fundamental principle of American manufacture, namely, the use of existing types which are turned out in large quantities with special tools with a view to the lowest possible cost of production. The electrical engineer for the purchaser has been permitted to draw up specifications which have tended towards the specializing of apparatus, necessarily interfering with rapid manufacture and low cost of the product. The disadvantage to the manufacturer is apparent. It is turning our large electrical works from manufacturing establishments into jobbing shops, cutting down their capacity, increasing their labor cost and lengthening the time that it takes to produce a given article. Looking at it, therefore, from the point of view of the manufacturer, the capacity of his plant is reduced and consequently his interest and general expense cost is higher; his labor cost is increased; and if he finds himself unable to increase his selling price, his shop must be run at a loss instead of at a profit.

The user is necessarily interested in low cost of production on the part of the manufacturer, as he cannot expect to purchase apparatus except at prices which yield a return to the maker. From this point of view alone it would seem to me to the interest of the user that he should co-operate with the manufacturer with a view to standardizing apparatus, eliminating unnecessary variations from a given type and providing specifications for machinery calling for a given capacity at a given efficiency. Such a course would lead to low cost of manufacture and consequently low selling price, coupled with rapid production.

Another objection to special apparatus is the expense and delay in obtaining duplicate parts in case of break-down. The fear of delay under such circumstances often necessitates the user carrying the duplication of his plant to a point entirely unnecessary when standard apparatus is used. Capital investment and consequently interest cost is thus increased, not only by the purchase of apparatus which of itself is expensive to build, but also by the duplication of investment which I have pointed out must of necessity follow.

A further point which should be borne in mind in connection with the lack of standard specifications is the opportunity that it gives to the unprincipled manufacturer to dispose of his second-rate apparatus to the uninitiated. We talk of a machine having a given capacity; but under what conditions should it operate to develop this capacity and how often does it occur that a dynamo machine is rated entirely too high and at the cost of its efficiency? How much miscellaneous material used in connection with the industry is absolutely unfitted for the purposes for which it is sold? Surely all of us, manufacturers and users, are interested in maintaining the highest possible standard of work and eliminating alike from our central station systems and the installations for our customers worthless appliances whose only recommendation is their apparent cheapness, whereas, as a matter of fact, they are really the most expensive that can be bought, because they are unfitted for the purposes for which they are intended. A proper consideration of this subject would not embrace alone the apparatus we are ourselves in the habit of buying for use in connection with our plants, but also the appliances used in connection with customers' house wiring. It should be borne in mind that faulty apparatus from one or more customers is, in the mind of the user of current, set down to the unreliability of the system as a whole. A central station customer seldom discriminates between a contractor who supplies a worthless device and a company supplying him with current. Standard specifications should therefore cover not alone the machinery used, but also the devices and material forming part of a customer's installation. This association has addressed itself at various times to the consideration of questions in connection with house wiring and has co-operated with the National Board of Fire Underwriters and other bodies with a view to establishing rules to be followed by contractors. I strongly recommend that this matter be taken up on a broader basis than heretofore, and that in conjunction with the technical societies we invite the co-operation of the electrical manufacturers with a view to standardizing apparatus and the specifications therefor, whether for use in the central station itself or in connection with the distributing system.

I do not want my remarks on this subject to be taken as in any way censuring the many electrical engineers who have by their special training and natural ability done so much to develop the industry with which we are connected. From my experience I am satisfied, however, that from the point of view of the user, the designing engineer who adapts his requirements to the standard apparatus of a first-class manufacturer, is able to produce a plant of more satisfactory character and more economical to operate than that designed by those engineers who I regret to say are sometimes influenced by the desire to use machinery which they can claim as their own handiwork rather than use something that would be quite as satisfactory and has the advantage of being the regular product of an established manufacturer.

The consideration of the subject of standard specifications would naturally include the preparation of specifications with relation to the manufacture of incandescent lamps. For several years past a committee of this Association has had this subject under consideration. It has been found practicable by a number of large central station companies connected with another association and buying from one manufacturer to purchase their lamps under specifications which provide for the testing of samples of the product of the factory, the payment for lamps supplied being based on the results of the tests. It seems to me that it would be possible to adopt standard specifications under which our members could purchase their lamps from any reputable lamp manufacturer. The importance of this matter will be appreciated when it is remembered that the cost of lamp renewals per unit of output exceeds $1.00 per ton of the cost of fuel in operating a central station, with the most modern steam plant.

SELLING PRICE BASED ON COST.

It is of prime importance to central station managers that they should sell the product they manufacture, namely, electric current, to the greatest number of consumers at the lowest possible price, and yet obtain a reasonable profit. For a number of years the basis of charge on the part of most companies has been a given unit price, with discounts for quantity. In the early days of the business some companies were in the habit of charging a fixed price per lamp per month, having no control whatever over the use of the product, but being necessarily responsible for the increased operating expenses caused by the wastefulness of customers, who could hardly be expected to economize, inasmuch as they paid exactly the same price for the use of light, whether they burned it one or twenty-four hours a day. A majority of these companies, however, following this last method realized at an early date the absurdity of distributing that for which they were not paid, and as a result I presume we can fairly assume that electric lighting business (with the exception of arc light service) is run almost universally on a meter basis. It is therefore unnecessary for us to discuss the question as to whether the measuring of current is a desirable thing in our business, as it is now generally recognized as a necessity. If you will make a careful examination of the factors entering into the cost of current you will very quickly come to a realization of the fact that interest is by far the most important single element, and that this item varies very considerably with the different classes of service furnished by a central station company. The interest factor in cost depends upon the yearly average consumption of your product by the customer; or, to put it another way, you can figure your interest on the basis of so much per unit of output at maximum load. For instance, take the two probably extreme classes of customers to whom the central station company supplies current for lighting purposes. On the one hand, you have an office building whose tenants only use artificial illumination for a very short space of time each day during the winter only. On the other

hand, you have a basement customer whose use of your product averages nearly one-half of the day of twenty-four hours during the whole year. Your investment, to take care of each of these customers is practically the same, therefore your total interest cost must be the same in both cases, but if you distribute this interest cost over the actual units consumed you will find that the tenant of the office building costs you for interest per unit of current sold many times more than does the occupant of the basement. There are of necessity as many different grades of customers between the two extremes I have mentioned as there are different classes of business and different characters of structures in which these businesses are conducted. Surely, if the cost of production varies according to the different conditions under which your customers use your product, it is but fair that the selling price per unit should vary correspondingly. If it does not, you, of necessity, encourage the use of electricity by customers whose business is unprofitable to you, and discourage the use of your product by customers whose business at a lower price would yield you a fair return. In past conventions the question of how to improve the day load for the purpose of raising the average output, what classes of business should be encouraged other than lighting to achieve this result, and the price at which we can afford to sell current to the operators of these different lines of business, have come up for discussion. At the last convention the realization of the fact that great differences exist in the elements governing the cost of product for different classes of lighting customers,. was ably presented by Mr. Arthur Wright, and he pointed out that the improvement of your load factor, the broadening of your curve and the rendering less acute of your peak is a matter within your own adjustment, providing that you will realize in considering cost with a view to making a selling price, that conditions are so dissimilar that the expense to you per unit of supplying two customers in the same block is likely to be widely different. Various plans have been adopted by a comparatively small number of companies to meet the conditions as we now know them to exist. Some companies have adopted the scheme of allowing certain special discounts providing the income per month per lamp connected exceeds a certain amount. Other companies charge one rate for current used during certain specified hours of the day and a much lower rate for the current used during the remaining hours of the dav. A third method is a system of discounts based upon the total consumption of current during a given period, considered in connection with the maximum consumption at any time during that same period.

These various methods all have the same object in view, namely, the meeting of the conditions of each individual customer, and yet at the same time earning a fair return on all of the investment provided for all of your customers.

In discussing this matter I have referred alone to interest cost because it forms so large a proportion of the total cost, but you will find that this same principle enters into a number of the other elements which go to make up your total cost. It would therefore appear to me that in considering the cost of generating electricity you should bear in mind that a large proportion of the items which go to make up the total are within your own control, and their amount per unit of output depends very largely upon the methods adopted in selling your product.

PUBLIC CONTROL AND PRIVATE OPERATION.

A subject of growing importance to a number of our members is the question of the public ownership and operation of the undertakings now operated by electric lighting companies. The agitation in connection with this subject has called forth a great deal of discussion, partly by those interested in it simply with a view to extending the influence of political parties, and partly by serious disinterested thinkers who believe that the best interests of the greatest number are to be obtained by the creation of a municipal socialism, which, if carried to its logical conclusion, must ultimately result in municipalities performing with others, such public service work as we are engaged in, and also in producing the food we eat and the clothes we wear. To those occupied in the management of electric lighting properties it does not seem possible that the movement in favor of municipal operation of electric lighting plants, based upon the assumption that a municipality can produce electricity cheaper than, or even as cheap, as a private corporation is well founded. We all realize, from the close attention we have to give to our own affairs, that self-interest and the necessity of getting a return on our investment are the first essentials to the economical administration of large enterprises. While I do not pretend to claim that electric lighting companies are beyond reproach, I wish to point out that many of the evils complained of as pertaining to corporate management are the direct results of the enforcement of unwise conditions through legislative action. Ill-advised efforts are often made by legislative bodies to secure advantages in the direction of control which cannot be obtained without giving an equivalent in protection to the industry. This causes the investor to feel that his property is being attacked and compels him to resist such legislation. The result is a feverish agitation, crimination and recrimination, between the would-be improvers of municipal government and the owners of corporate properties without reaching a conclusion satisfactory to either. The fallacy of the so-called reformer's theory results from looking only at what he calls the injurious effects of corporate management without taking into account its indisputable benefits. He does not seek for the cause of the trouble. If reformers will take accurate account of all the points in the problem they will discover that the evils complained of result from errors in legislation designed to determine the relations between municipal bodies and electric lighting companies. It seems to me that the claim that municipal operation is the universal cure for all diseases for which electric lighting companies are supposed to be responsible, merely proposes the substitution of political in the place of industrial management. This raises the question: Is the administration of municipal affairs in the various cities throughout this country so economical as compared with the management of private industries and the class of service rendered so efficient as to justify the increasing of the burdens already imposed upon municipal government? It appears to me that a correct division of power and responsibility requires political government to control private industrial management. Where political government and industrial management are merged into one interest, the power of control is seriously impaired, since a political administration cannot be reformed without overturning the party in power.

I cannot bring myself to the belief that the citizens of this great country are in fact opposed to large aggregations of capital in corporate form, as such aggregations are absolutely necessary to the operation of all great undertakings by private enterprise. It is as impossible to operate such vast affairs with individual capital, as a personally owned business, as it is for us to live without municipal, state and national governments. The misunderstandings which from time to time occur between communities and the managers of electric lighting companies will, to my mind, disappear entirely if the relations between the two are correctly founded on the basis of public control, with corresponding protection to the corporations operating this industry. It would seem to me to be a very proper function for this association to address itself to educating the public to a definite legislative policy which will be fair to the municipalities, securing to the public the best service at the lowest possible price, and protect corporations by giving them franchises, which, while conserving municipal control, will insure to the investor the permanency of the undertaking.

COMPETITION IS NOT THE TRUE REGULATIVE FORCE.

It is supposed by many who discuss municipal affairs that the granting of competitive franchises for public service work is the true means of obtaining for users the lowest possible price for the service rendered, whereas, as a matter of fact, the exact opposite is the ultimate result. This is proved by results in all large cities where the most severe competition has taken place. Acute competition necessarily frightens the investor, and compels corporations to pay a very high price for capital. The competing companies invariably come together, and the interest cost on their product (which is by far the most important part of their cost) is rendered abnormally high, partly owing to duplication of investment and partly to the high price paid for money borrowed during the period of competition. The selling price of a service should be based on its cost, and in any business such as public work, where the investment is large and the annual turn-over is comparatively small, if the item of interest be unnecessarily augmented, it must be reflected in the price paid by public and private users.

While it is not supposed to be popular to speak of exclusive franchises, it should be recognized that the best service at the lowest possible price can only be obtained, certainly in connection with the industry with which we are identified, by ex-

clusive control of a given territory being placed in the hands of one undertaking. In most European countries public service operations enjoy exclusive franchises, under proper control, and are able to obtain capital for their undertakings at the lowest commercial rates, thus materially affecting the cost of their product, of which interest, as I have already stated, is necessarily so great a part. In order to protect the public, exclusive franchises should be coupled with the condition of public control requiring all charges for services fixed by public bodies, to be based on cost, plus a reasonable profit. It will be found that this cost will be reduced in direct proportion to the protection afforded the industry. The more certain this protection is made the lower the rate of interest and the lower the total cost of operation will be, and consequently, the lower the price of the service to public and private users. If the conditions of our particular branch of public service are studied in places where there is a definite control, whether by commission or otherwise, it will be found that the industry is in an extremely healthy condition, and that users and taxpayers are correspondingly well served.

COMPENSATION FOR FRANCHISES.

When prices for services are based on cost it matters not whether in the establishment of a system of legislative control provision is made for paying a portion of the receipts direct to the municipality. If the public demands a percentage, surely we can afford to pay it, as it would simply be added as an item of expense on which our selling price would be figured. If the public does not demand a percentage, this selling price would be proportionately less. It is simply a question as to whether our municipal bodies prefer to raise a portion of their income by taxing their citizens through the agency of public service corporations, or whether they prefer to raise that portion of their income by collecting it direct from citizens themselves. Revenue raised by a percentage on gross receipts of the electric lighting business would, at the present time, however, seem to be somewhat unfairly obtained in cases where the selling price is subject to legislative control and based on cost of service, as the result would be that a small minority of citizens using electricity would be forced to contribute largely to the public revenue, whereas the benefits enjoyed therefrom would be to the advantage of the whole community.

TAKING PRIVATE PROPERTY FOR PUBLIC USE.

Another point that should be included in a proper scheme of public control is a condition under which the municipality would have the right to purchase the undertaking. Such a right should include a direct obligation on the part of the municipality to purchase the property at a fair price whenever it is thought desirable that the industry should be operated by the municipality. The possibility of the exercise of the right of purchase by the municipality would of itself make it to the interest of the owners of the property to do their full duty in their relations to the public. On the other hand, if a community licenses a corporation to perform a certain public service, and if that corporation invests its money and develops its business, surely it is unfair for that community to go into the same line of public service work itself without first purchasing the existing plant. If this is not done the value of private property will be destroyed without just compensation being made therefor in an attempt to secure a public benefit. I do not believe that the people as a whole are so unfair as to demand that such a course shall be taken.

My recommendations on the subject, which I have just presented, are by no means original. Most public service corporations in Great Britain are run on practically the bases indicated, and in more than one State in the Union corporate legislation has taken the same direction.

I would summarize the position which I think we should take on this subject in just two sentences.

First—Franchises granted to public service corporations should secure them the same degree of protection in their rights to their property as is enjoyed by other investments.

Second—Public control of charge for service based on cost plus a reasonable profit, and eliminating the factor of competition, is the proper safeguard for the interests of users, taxpayers and investors.

ATTICA, IND. The Attica Electric Light Company are increasing their plant by the addition of a 125 h. p. Ball engine, built by the Ball Engine Company, Erie, Pa.

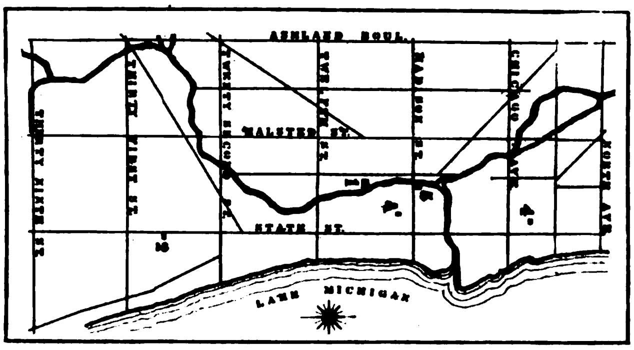
General Distribution from Central Stations by Direct Currents.[1]

BY LOUIS A. FERGUSON.

THE subject of Central Station distribution by direct currents is one which is so familiar to many of you that I hesitated when asked to write this paper, feeling that it would be difficult to present to you any new thoughts or experiences, so I trust you will pardon me if in the attempt to precipitate discussion and bring to the attention of the meeting the ideas and experiences of others, which is, after all, the object of my paper, I may trespass upon ground previously explored.

Nor do I wish to be construed as advocating blindly the general use of direct currents under all conditions, for both transmission and distribution of electricity for lighting and power purposes in cities and towns, for records will, I think, clearly show that the writer was the first of the so-called Edison Central Station men (who have represented the direct current idea in Central Station lighting) to advocate the introduction of the alternating current as a means of effecting important economies in the operating of the direct current distribution systems, and also vastly extending their field of operation, which without the combination of alternating currents might have remained, despite their distinct advantages, unfortunately limited to a comparatively small and closely populated area.

The general design of the modern direct current Central Station and its equipment has been fairly well established within the past five years, and while it was originally the custom to erect the generating stations as nearly as possible in the electrical centre of the city or town, it is now generally conceded that direct current may be more economically distributed from a condensing station situated even a mile distant from the electrical center than from a non-condensing station located at the electrical centre of the city, and it has been further demonstrated that the former practice of building many central generating stations in various centres of distribution in cities is to be supplanted by the use of one or two large condensing stations generating direct current for distribution throughout the business district if the station be within one mile of the electrical centre of the district, and alternating current for transmission to sub-stations located at the electrical centres of districts more remote from the main generating station. In some cities water for condensing purposes may not be easily obtainable within a distance of one mile, and the location is then merely a question of total cost of land, building and transmission lines to the various distributing stations, proper consideration being given, of course, to the limitations of line voltage and insulation.



CHICAGO EDISON AREA OF DISTRIBUTION.

In order to show the workings of the first mentioned type of modern direct current Central Station systems, I will explain in a general way the method of distribution employed in the system of the Chicago Edison Company, which I think fairly represents the latest development in direct current distribution, and leave the explanations of the methods of direct current distribution in other cities to the representatives of the companies operating them.

The system of distribution is a solid net work of underground conductors on the three wire system, extending from North avenue to 39th street, a distance of six miles north and south, and from Lake Michigan to Blue Island avenue, a distance of one and one-half miles east and west. The entire net work is

[1]Read before the Nat. Elec. Light Ass'n, Chicago, June, 1898.

continuous from end to end, and is supplied at present from four central stations, all connected in parallel through the net work and each feeding into it. The two large stations located at Harrison street and Washington street on the Chicago River, and known as Stations No. 1 and No. 5 respectively, are condensing plants, while the stations on the north side and south side, located at North Clark and Oak streets and Wabash avenue and 27th street, known as Stations No. 4 and No. 2 respectively, are non-condensing.

The total current furnished to the net work at the time of maximum load of the system in the winter of 1897 was 50,730 amperes, and is divided as follows:

	Amperes.	Per cent. of total.
Station No. 1	35,600	70.2
Station No. 5	7,600	15.0
Station No. 2	3,400	6.7
Station No. 4	4,130	8.1
	50,730	100.00

The total low tension direct current kilowatt hours output for the stations for the fiscal year of 1897 was 15,255,466, divided as follows:

	Low tension Kilowatt hours.	Per cent. of total.	Maximum station voltage.	Yearly average station voltage.
Station No. 1	11,335,618	74.3	149.	126.2
Station No. 5	2,314,473	15.2	142.5	129.6
Station No. 2	808,158	5.3	125.0	119.0
Station No. 4	797,217	5.2	123.5	120.1
	15,255,466	100.0		

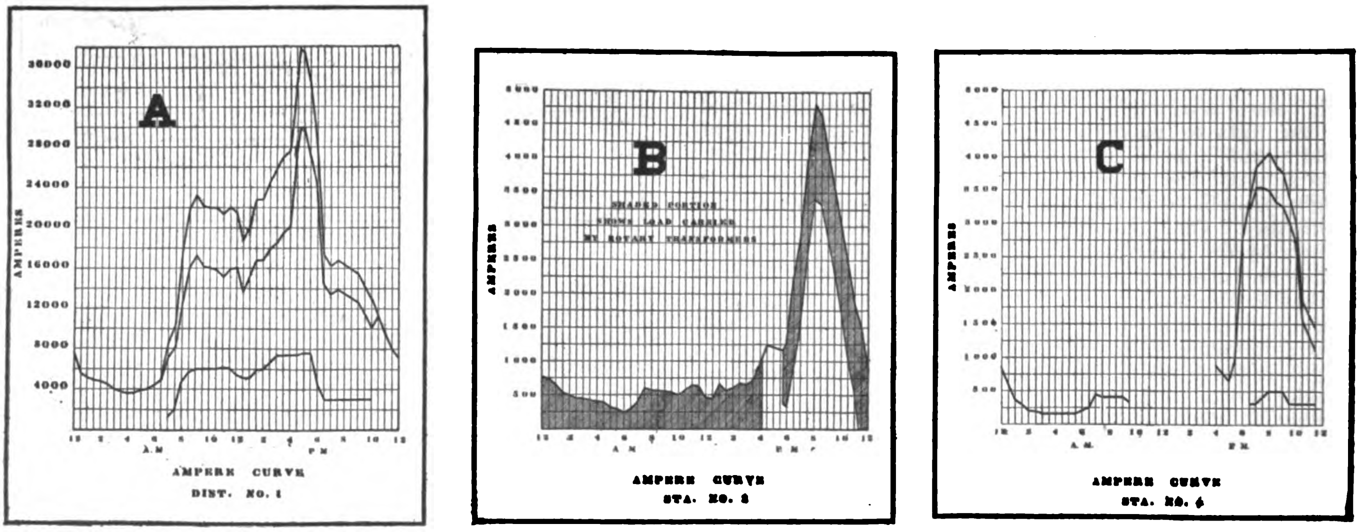
The pressure at the feeder ends throughout the system is maintained at 115 volts on each side of the three wire system. Although the maximum station pressure is 149 volts, the average pressure of all stations for the year is 126.2 volts, giving an average loss of pressure of 11.2 volts or 8.8 per cent., which means an average yearly efficiency of distribution of 91.2 per cent. from the station switchboards to the customer's meter.

the output of districts No. 2 and No. 4, from dusk until midnight daily, and ultimately they will furnish all of the output of the territories mentioned, and all of the energy required for alternating transmission lines into the outlying districts of the city and its suburbs.

The load curves "A" here shown, indicate the amperes furnished in district No. 1, by Stations No. 1 and No. 5, the small lower curve representing that delivered by Station No. 5, and the lower large curve showing that delivered by Station No. 1, and the upper curve representing the total amperes delivered to district No. 1.

The distribution of current from these two stations to the underground net work is as follows:

From Station No. 1 to the Adams street sub-station is laid an immense trunk line known as the Adams street trunk line, having a total cross-sectional area of 66,000,000 circular mils, 28,500,000 circular mils being ordinarily connected on the positive and negative sides and 9,000,000 circular mils in the neutral. The length of this trunk line is 3,340 feet, and is made up of fifteen special Edison tubes, each 3,000,000 circular mils area, laid directly in the ground, and fourteen 1,500,000 circular mils stranded rubber insulated, lead covered, and juted cables drawn into cement lined iron ducts. The trunk line on leaving Station No. 1 goes down a shaft sixty feet, thence through a brick tunnel built especially for it in the river bed to the east side, where it rises again in another shaft sixty feet into the tunnel house, where a small switchboard is located. The portion of the trunk line in the shafts and tunnel, which is 430 feet in length, is made up entirely of cables, of these forty-five are 1,000,000 circular mils Siemens jute insulated and fourteen are 1,500,000 circular mils General Electric rubber insulated, leaded, asphalted and iron armored submarine cables, each supported on iron racks. Where the cables hang vertically in the shaft, the cable is supported by the iron armored sheathing clasped between iron plates on a heavy cast-iron ring. The copper conductors thus hang in a sort of basket, the strain being distributed throughout the length of the cable. At the tunnel house the forty-five Siemens 1,000,000 circular mils cables connect with



LOAD CURVES, CHICAGO EDISON CO.

The centre of distribution in the business district of the city is at Adams street, between Clark and LaSalle streets. Station No. 1, which, as has been shown, furnishes 74.3 per cent. of the total low tension output, is located on the Chicago River at Harrison street, 3340 feet distant from the centre of distribution at Adams street. Station No. 5, which furnishes 15 per cent. of the total low tension output, is located on the Chicago River at Washington street, and is 4,500 feet from Station No. 1, and 3,000 feet from the Adams street sub-station.

These two stations furnish all the low tension output for the district bounded by the river on the north, Harmon Court (approximately) on the south, Lake Michigan on the east and the river on the west. They also furnish all the energy for the entire low tension system of the city during the hours from midnight until dusk the following afternoon, and a portion of

fifteen 3,000,000 circular mils single pole Edison feeder tubes, and together with the fourteen 1,500,000 circular mils cables are mounted on racks in a large subway, into which the duct line enters about 200 feet east of the tunnel house. At intervals of about 500 feet manholes are built in the Edison tube portion as well as in the conduit portion of the trunk line, thus affording a quick means of locating low insulation points as they develop. Each of the tubes and cables is provided with an amperemeter at Station No. 1, and with switches at both ends so that they may be completely disconnected from the system in case of trouble. Two of the 3,000,000 circular mils tubes are provided with throwover switches and arranged so that they may be quickly connected either to the positive or neutral or negative or neutral at will. All of the cables are provided with throwover switches on both ends, so that they may be operated

either as positive or negative at will, thus providing for any possible contingency that may arise. At the Adams street sub-station the trunk line feeds into the main bus-bar in the Distribution Room, and from the switchboard forty-two feeders radiate to various points in the business district, ranging in size from 250,000 circular mils to 1,000,000 circular mils, and in length from 290 feet to 2,831 feet, the average size being 485,000 circular mils, and the average length of feeder 1,373 feet.

The maximum current in amperes carried over the trunk line and distributed from the Adams street sub-station last December was 34,400 amperes, the maximum loss of pressure on the trunk line being 12.4 per cent., and to the customers' meter 22.8 per cent., the distance to farthest feeder end being 6,171 feet. In addition to the current furnished to the trunk line, Station No. 1 also delivers from its main bus-bar current to the two 1,000,000 circular mil feeders which feed into two points in the southern portion of the business district. One of these feeders terminating at Wabash avenue and Harrison street is 3,800 feet in length and carries with maximum station pressure 780 amperes on each side, the other terminating at Eldredge Court and State street is 4,800 feet in length and carries with maximum station pressure 620 amperes on each side. The supplying of district No. 1 by Station No. 5 is done in much the same manner as that just described by the two feeders from Station No. 1 into the southern portion of the district. From Station No. 5 eight feeders, varying in size from 400,000 circular mils to 1,000,000 circular mils, and in length from 2,175 feet to 4,445 feet, terminating at different points in the northern section of district No. 1, deliver a total of 7,600 amperes at maximum station pressure of 140 volts, the amount of current furnished during the run being only enough to maintain standard system pressure at the feeder ends, the curve of station voltage following very closely that of Station No. 1.

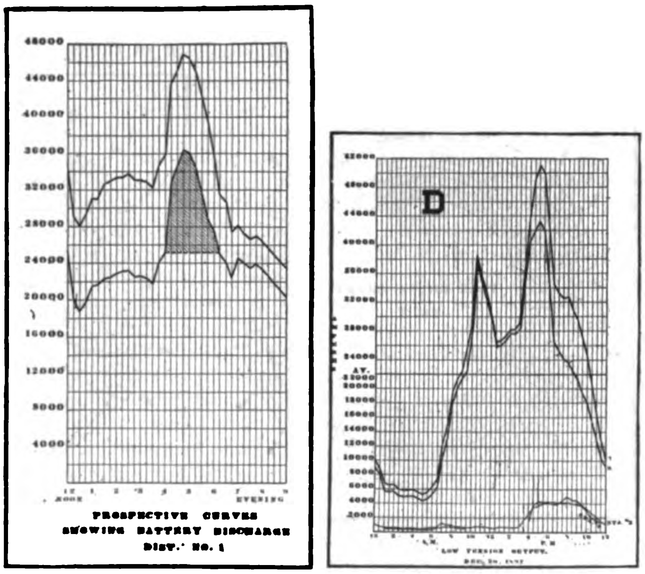
Station No. 2, which is now really a rotary transformer substation, is 17,500 feet from Station No. 1, and 14,300 feet from Adams street sub-station. The load diagram "C" shows the amperes delivered to District No. 2, the cross hatched portion representing the current furnished through the rotary transformers and the unshaded portion representing the current furnished by the dynamos in Station No. 2, the dynamos and rotary transformers operating in parallel on the three wire system. The upper curve shows the total amperes delivered to District No. 2.

Station No. 4, which now operates only from dusk till midnight, and will later become a sub-station, is 11,500 feet from Station No. 1, 9,000 feet from Station No. 5, and 8,000 feet from Adams street sub-station. The load diagram "C" show the amperes delivered to District No. 4. The portion of the curve from midnight until 3:30 p. m. on the winter day and until 6:30 p. m. on the summer day is furnished from District No. 1 through the inter-connected underground net work, the District No. 4 being, during these hours, merely an extension of District No. 1, and having no distinct supply delivered through its own switchboard. From dusk till midnight the generating plant in Station No. 4 is operated, and the current is delivered as shown by the next to the highest curve on the diagram, the low curve marked No. 5 representing the amperes furnished by Station No. 5 to District No. 4 over a direct current tie line between the switchboards of the two stations. The tie line is made up from one feeder running out of Station No. 5, originally feeding into District No. 1 and now connecting by means of River cables with a feeder out of Station No. 4, which formerly fed into the district at a southern point. This tie line is switchboard, thus relieving the network between Districts No. 4 by connecting onto the main bus in Station No. 5 and allowing it to take a small current and deliver it to Station No. 4 switchboard, thus relieving the net work between Districts No. 1 and No. 4 of some of the work. Between the hours of midnight and 8 o'clock in the morning there is only one low tension direct current generating station operating (Station No. 1) supplying direct current to District No. 1, and through the net work to District No. 4.

District No. 2 is supplied from Station No. 1 by means of a converse rotary transformer connected to the 250 volts direct current bus-bars, converting to three phase alternating current at about 160 volts. By means of step-up transformers this is raised to 4,500 volts, and at this pressure the energy is transmitted by three phase underground transmission line to Station No. 2, where it is reduced by step-down transformers to about eighty volts and converted by means of rotary current transformers to direct current at about 115 volts.

For the permanent conversion of Station No. 2 into a substation a pair of special 200 kilowatt generators are being installed, directly coupled to the existing 600 h. p. triple expansion engines in Station No. 1. Each generator is provided with a commutator and a set of three collector rings, and is designed to deliver from the same armature direct currents and three phase alternating currents, the direct current sides of each pair of machines being connected in series to form a three wire unit, and the alternating current sides, after passing through transformers stepping up to 4,500 volts, being connected in multiple. The alternating current from these machines will be taken to supply the transmission line to Station No. 2, and the balance of the capacity of the machines will be delivered directly into the main direct current bus-bar of Station No. 1, thus keeping the unit operating at full load and maximum efficiency during its run. The peak of the load in District No. 2 arrives later than the peak of District No. 1, so that the same investment in steam and electrical machinery may be employed to take care of a portion of the peak in both districts, these special generators constituting a reserve or surplus for the direct current equipment of Station No. 1.

Lest I might wander from the subject of the paper, I shall not now dwell further upon the question of transmission of energy by alternating currents, although it plays an exceedingly important part in the distribution of electricity by the Chicago Edison Company.



LOAD CURVES, CHICAGO EDISON CO.

Uniformity of pressure throughout an incandescent electric lighting system is absolutely essential to commercial success. To accomplish this different methods have been proposed at different times. It often happens that the original plan of distribution, laid out by the constructing engineer, does not meet the requirements, after several years' growth of the business, for in all cities lighting business may localize at certain special points, and so demand a remodelling of the existing system of conductors, or require some means of correcting for the inequalities of pressure that are due to the unevenly distributed load.

In the Edison systems built prior to 1890, it was customary to introduce in series with each feeder a resistance box with capacity to carry the entire current of the feeder and of resistance much greater than that of the feeder itself. The resistance box is commonly known as a feeder equalizer. From the end of each feeder where it connected with the mains, a set of pressure wires was run back to the station and there connected to pressure indicators. The method of regulating was to designate the feeder supplying the most important district in the system the standard feeder, and to keep its pressure constant, say 110 volts. Each pressure indicator of the other feeders was differentially wound, so as to receive the pressure of the standard feeder as well as the pressure of its own feeder. When

there was any difference of pressure between the standard feeder and a given feeder, the latter's indicator needle would deflect to one side or the other according as the pressure on that feeder was higher or lower than the standard, and if equal of the standard, the indicating needle would stand in the centre. If, then, any indicator showed that its feeder was low in pressure, some resistance would be cut out of its feeder equalizer, and, the resistance diminishing, the volts loss on the feeder would then become less, and thus the feeder could be brought to the same pressure as the standard. If the pressure of the feeder were high, the operation would be the reverse.

With this method of regulation, the entire output of the station must be at such pressure at the station switchboard as will permit the delivery of the correct pressure at the end of that feeder, the product of whose load and resistance is greatest in the system. There are some large stations in America operating to-day on this plan of regulation, notwithstanding that it is an expensive and troublesome one. Another method of regulating, which may be employed where the load is fairly well distributed, is by cutting out the feeders which are high and forcing the current to travel through the remaining feeders and the mains, thus increasing the fall of pressure to the end of the feeders which were formerly high.

The only economical and safe way to regulate in a city where the distances are not abnormally great, and where the load is fairly well distributed, is to so design the conducting system that it will be self-regulating, that is, so that it will require no change of the resistance of feeders or anything of the kind.

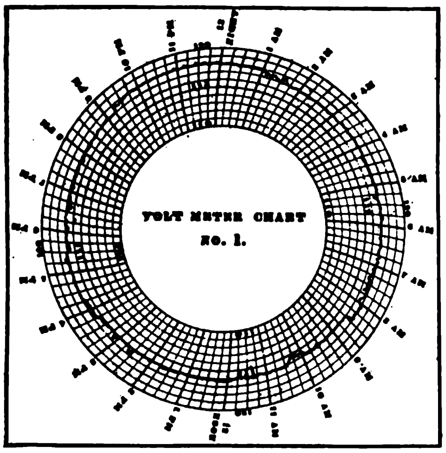


Chart No. 1, represents the pressure for 24 hours on the direct current distribution system in the business district of Chicago, the average deviation from the mean pressure is less than one volt.

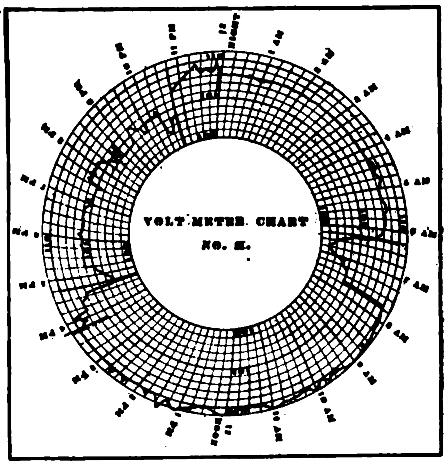

Chart "H," represents the pressure on one of the circuits of a single phase, house to house transformer, alternating system in Chicago.

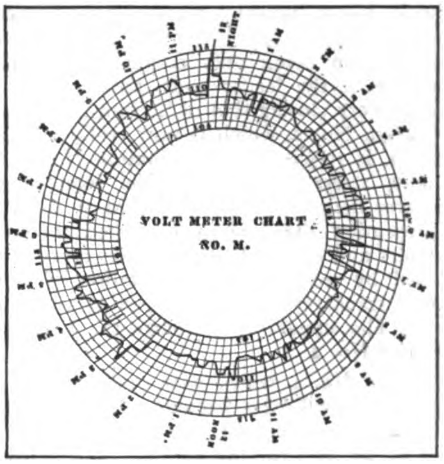

Chart "M," represents the pressure regulation of an alternating current system on a long avenue, where are used primary feeders with four 15 k. w. transformers, the secondaries in multiple on the three-wire system.

A good conducting system should have an ample number of feeders reasonably close together, and the connecting mains should be of generous cross sectional area.

A valuable adjunct to a station, where there are one or two straggling feeders of great length so located that they cannot be interconnected with the general system so that they may be benefited by such connection, is what is known among the Edison companies as the "Booster." The "Booster" is a direct current dynamo wound for a large current and low voltage, and is used for raising the pressure of the station and of the feeders which are ordinarily low. The "Booster" dynamo should be series wound and so designed that its voltage will be proportional to the current passing through it, the speed remaining constant. It is connected in series with the feeder, whose pressure is to be raised, and is belted to or directly connected with a motor which drives it at the speed for which it is designed. Its action is as follows: The current passing out on the feeder also passes through the field and armature of the "Booster" dynamo, and an electromotive force is thus added to that already existing on the feeder due to the dynamos of the general system. As the load on the feeder increases, the electromotive force of the "Booster" dynamo increases proportionately, and adds to that of the feeder, thus overcoming the loss of pressure due to the increased current in the feeder, which enables the feeder to deliver the proper pressure at its mains. The "Booster" may also be employed to raise the pressure of a number of feeders which are connected to an auxiliary bus-bar. In this case, the "Booster" would be connected between the main bus and auxiliary bus, and would carry all the current of the auxiliary bus, raising the pressure of it as its load increases, and decreasing as the load decreases, as described in the case of the single feeder.

In some central stations two or more potentials or pressures are used, certain dynamos working on a bus-bar at one pressure and the other dynamos working on another bus-bar at different pressures.

This method is only economical when the dynamos can be worked very near the maximum load, which is not often the case. In some cities the dynamos in central stations or machinery or storage batteries in sub-stations feed into one general system at different points, each station or sub-station operating at such pressure as will deliver the same voltage at the feeder end of the mains. This is, without doubt, the method to be recommended as giving the best efficiency and assuring reliability of service throughout the system.

With the method proposed in case of accident to any one station, either by fire or lack of water supply, the whole system will not be shut down, but each station will take its share of load which comes from the shutting down of the disabled station.

Municipal legislation in all large cities requires, and very justly so, that the wires for the distribution of electricity for lighting and power purposes should be laid underground. The Edison companies throughout the country use a standard system of underground, the mains and feeders consisting of japanned iron pipe in which are three solid copper wires or rods insulated from each other and from the iron pipe by an asphaltum compound. These pipes or "tubes," as they are commonly called, are twenty feet in length, the copper conductors projecting three inches on each end, making the total length of each pipe twenty feet six inches.

The copper conductors are connected together by means of a flexible coupling, composed of a stranded copper cable about eight inches in length, and having copper terminals on either end, and which are provided with a circular opening of such diameter as will permit the reception of the copper conductor of the tube. The copper terminal is heated by the flame from a blow lamp, and the conductor is soldered into the terminal.

After the three couplings are connected an iron ball clamp is bolted on to the tube near the end, and a cast-iron oval-shaped coupling box is laid over the copper joint and fastened together by bolts and nuts. The coupling box is then filled with hot insulating compound, and after this has settled by cooling, the box is again filled and the opening covered by plugs.

At each street intersection these tubes enter a junction box. The junction box is a cylindrical cast-iron box in the centre of which is a cast-iron upright standard carrying three rings of flat copper bar. To one of these rings all of the positive conductors are connected, to another ring all the negative conductors, and to the remaining ring all of the neutral conductors are connected in a similar manner.

Many of the junction boxes are fed by a feeder direct from the central station, the feeder, when Edison tubes are used, being laid in the same manner as the mains before described. The feeders in a three-wire system consist of three conductors, as in the case of mains, with the exception that one conductor which

is used as a neutral has usually one-third the area in cross section of either of the two other conductors. Feeder tubes are made in various sizes, from 250,000 c. m. up to 3,000,000 c. m. Each feeder tube also contains three small insulated copper wires, which are connected in each coupling box to the corresponding wires in the next tube, thus making a continuous circuit from the feeder end in the junction box at street intersection back to the station. At the generating station these wires connect with a pair of volt meters, and at the end of the feeder they are connected through fusible strips to the copper rings in the junction box, thus giving in the station the pressure or difference of potential at the feeder end. By means of the junction boxes the system becomes one grand net work of conductors connected in multiple and fed at many points by feeders from the central station, similar to that of a well designed gas or water system in a large city. By means of this net work of mains the electrical pressure is equalized throughout the system, and the current is distributed properly among the feeders. Every mechanical and electrical detail of the system is very carefully worked out and absolutely interchangeable, and it is without question, when cables are used for the feeders, the most complete, most easily operated, and most permanent underground system yet devised for the distribution of electricity for large cities using a direct current system of 500 volts and under. With this system the customers are almost absolutely certain to have continuous service, as they are fed from two points under ordinary conditions, and should the main in their block burn out, it is nearly always possible for the company to feed the customers from one or another junction box. The method of coupling affords a perfect house to house system of distribution, and renders the placing of services a very easy and simple matter. The system is very easily laid down, and its maintenance compares favorably with other methods of distribution.

The maintenance of good presure regulation at the customer's meter is very much more easily effected with an interconnected direct current distribution such as has been described, than with the ordinary alternating current central station system, such as has been exploited in this country.

Owing to the parallel operating of direct current dynamos and distribution systems the fluctuations in the pressure, due to change over from one machine to another, so prevalent in the ordinary American alternating current central station, and so annoying to customers, are eliminated, and a carefully operated direct current central station should show a pressure chart with an average deviation from the mean of less than one volt.

It is possible, of course, and often the careless practice in direct current stations to have bad fluctuations of pressure at the times of change over, and also irregularities at other periods, but there is absolutely no excuse for their existence in a well operated and well planned direct current system.

The parallel operating of the generators greatly simplifies the maintaining of uniform pressure regulation at the lamps, since when several units are connected to the common bus-bar the regulation for the entire system may be effected by careful attention to one unit, whereas in alternating current stations where the generators do not operate in parallel it is necessary, in order to even approach the uniformity of pressure regulation which exists in direct current systems operating in parallel, to regulate the pressure accurately on each unit, which is seldom done in practice. Besides the better regulation possible with parallel operating of the dynamos, a further distinct advantage is derived from the economy effected by proper division of load among the units in the stations, this being particularly marked when the distribution systems are also interconnected. Each unit, irrespective of size, may be usefully and efficiently employed at the period of maximum load, and the amount of idle or uneconomically employed investment is reduced to a minimum.

To illustrate the comparative accuracy of regulation obtainable in an interconnected direct current system, and in the ordinary type of independent circuit alternating current system, let us refer to the pressure charts shown in the enclosed sheets.

If the engineer designing a system employing alternating current in the distribution, expects to obtain first-class pressure regulation, he must follow those lines laid down by the engineers who have developed the modern direct current distribution system. The distribution system of mains should be interconnected, forming one grand net work of conductors with large transformers, located at points where feeders would terminate if it were a low tension direct current system, and to these transformers should be brought the primary feeders from the central station, provided with boosting transformers or induction regulators. Pressure wires from the secondaries of the transformers should be brought back to the station so that the pressure on the ends of the mains may be known and properly controlled. Such a system will be described to you in detail by Mr. Wagner, and I am sure he will agree with me when I say that the single-phase, house to house transformer, separate circuit alternating current system, such as has been generally exploited in this country has nothing to recommend it to the central station manager, either from a purely engineering or financial standpoint, although it has fulfilled its mission as a pioneer in the introduction of electric lighting in scattered districts.

One of the advantages to be derived from the use of direct current distribution as distinct from alternating current distribution, is the employment of storage batteries. They may be adopted for use in various ways, in sub-stations in outlying districts where the load factor of the district is very small, in the central stations themselves to deliver the entire output during period of minimum load, at the centres of distribution for discharging during the peak, as auxiliaries in rotary transformer sub-stations for discharge use at the time of the maximum load in the main central station. In addition to any one of the various ways which the battery may be employed, it always acts as a reserve, guaranteeing the consumer good service, in much the same manner as a bank surplus is a guarantee to the depositors in cases of financial emergency.

Storage batteries when installed in central stations or centers of distribution are usually connected to the main bus and allowed to float on the system taking a charging current from the bus or discharging into the bus according to the load on the system, the generating units being worked at such load as will insure the best efficiency of the entire system.

Batteries are economically valuable in connection with the distribution of direct current in systems whose load curve has an average peak width of not more than two hours, since the investment required for storage batteries to carry the peak having an average width of less than two hours is less than the investment required in steam and electrical machinery to do the same work. The storage battery also has the same value that exists in the case of moving machinery as a reserve in meeting sudden increases of load, provided such increase of load does not continue for a sufficient period to wholly discharge the battery and insufficient time remain for recharging before the ordinary load peak of the system appears at the regularly appointed time. Such a condition is rarely and I might say almost never met with, although in rare instances we may approach this condition.

The steam and electrical machinery is rated by the horse power or kilowatt, and the duration of the load peak does not influence the value of the investment since the machinery may be operated for the full twenty-four hours at its maximum capacity. The storage battery, however, is rated by the horse power hour or kilowatt hour, and the investment is nearly directly proportional to the number of hours during which it discharges the maximum capacity, so that if we required the battery to be prepared to carry the full peak prolonged for seven or eight hours every day the investment in battery would be enormous as compared with steam and electrical machinery to furnish the same kilowatt hours output. Illustrative of such contingency, let me refer you to the load diagram marked "D," representing the load in the business district of Chicago, December 20, 1897. This is a very extraordinary curve, illustrating the limitation of the storage battery and the posibility of its being rendered ineffective had the early morning peak extended to the arrival of the regular afternoon peak, without affording sufficient time for recharging the battery.

The storage battery has a very distinct value, which is seldom recognized and employed to its full advantage, when located at the central distributing point of a system with feeders radiating to various points in the net work. The battery may be provided with two or more end cell switches, so arranged that they may be connected in multiple and feed into the main distributing feeder bus, or they may connect also to one or more auxiliary bus-bars with a different number of cells in series, feeding into each bus, thus providing two or more potentials at the centre of distribution. It will be found that when only one pressure is

maintained at the centre of distribution during the time of maximum load of a large district that the pressure at the ends of the short feeders will be somewhat higher than the standard and they will be overloaded, and at the end of long feeders the pressure will be lower and the feeders underloaded, although the pressure variation at other times may be negligible. Under such conditions the storage battery becomes exceedingly valuable, for by arranging it to operate at two or more potentials, the long feeders may be connected during the time of maximum load to the auxiliary bus or busses and additional current forced over them, utilizing their full capacity and maintaining a uniform feeder end pressure by means of an investment in end cells very slight as compared with the investment in additional feeders and mains required to accomplish the same result.

The direct current distribution system is very much better adapted to electric elevator work than the alternating current distribution, and as far as I am able to learn there has not yet been developed a commercially successful direct coupled electric elevator capable of running at varying speeds and operated by alternating currents.

The direct connected electric elevator is a piece of apparatus which is of the greatest value to the central station companies, since it is practically the key to the isolated plant situation, and with its aid we are enabled in a large percentage of instances to show to the owners of large mercantile establishments and buildings a decided saving in the purchasing from the central station company of electricity for lighting, elevator and general power service as compared with the cost of operating an isolated plant, using hydraulic elevators. The immense advantage to the central station companies in being able to supply commercially successful electric elevator service economically. may be realized when we consider that there is connected to the systems of the Edison companies in New York, Boston, Brooklyn and Chicago 15,000 horse power capacity in direct connected elevators, representing a gross income of approximately $375,000 annually. At the present time alternating current distributing systems confine us to the use of continuous running motors belted or geared to the elevator pump or winding equipment; but such an arrangement is not fitted for first-class passenger service and is very uneconomical, and similar equipments using direct current motors were in use ten years ago and have long since become obsolete and have been entirely superseded by the direct coupled electric elevator which operates for approximately one-half the cost.

The use of low tension constant potential arc lamps connected in multiple to the distribution system has made rapid strides during the past three years, and in New York, Brooklyn, Boston, Chicago and other cities is fast superseding the use of series arc lamps wherever the low tension mains operate, and the day is not far distant when series arc lamps will be employed only in the outlying districts where there is not sufficient business to warrant the extension of the low tension distribution system. The competition effected by the Welsbach gas burner has done much to develop the constant potential arc lamp, and it is safe to say that with incandescent lighting alone the central station companies are rendered helpless against the improved gas burners; but a successful competitor has been found in the use of the three and one-half ampere direct current enclosed arc lamp, and as proof of this we have only to compare the results of the central station companies in the large cities, where these small arc lamps have been employed, with the conditions existing in the small towns, where alternating current systems of distribution furnish incandescent lighting only. In the latter places the Welsbach light is found to be in general use and is affecting very seriously the earnings of these small central stations owing to the lack of an alternating current arc lamp, which would answer the purpose of the small ampere arc lamp used in connection with direct current systems. Although very much has been done within the last year in the development of the large alternating current arc lamp, it is still far from being in the state of perfection, and cannot be said to compare practically or economically with the constant potential direct current enclosed arc lamp.

The use of motor cycles and electric cabs employing storage batteries is becoming more popular every day and in London and Paris they are used very largely, in Paris an Automobile Club having been formed by people owning motor cycles. The central station companies using direct current will undoubtedly find a profitable outlet for their product as the motor cycle becomes more popular, and by locating charging stations for the motor cycles along the central station mains the use of the motor cycle will become more extended.

When we consider the many practical advantages inherent to the direct current system of distribution which add so greatly to the commercial success of a central station company, it would seem that the original investment required to establish the plant and system should not be the only question affecting the selection of the system to be adopted.

It is universally conceded by all competent and unprejudiced engineers that the alternating current system of distribution in a closely settled district, which shall approach in commercial value the direct current distribution system, shall be one which has for its basis an interconnected system of secondary mains, with transformers of large capacity, and high pressure feeders from the central station to these transformers and generators in the station operated in parallel, as previously described. Therefore the cost of the distribution net work in the case of the alternating current system will not be less than that of the direct current net work, and the cost of transformers, high pressure feeders and alternating current dynamos should be compared with the cost of low tension feeders and low tension dynamos of the same capacity, these forming the only points of comparison. The investment in each case depends merely upon the advantageous location of the central station in each individual city.

I have shown in the early portion of the paper that in a large distribution system such as exists in Chicago, that seventy-five per cent. of the total energy supplied to the system is delivered to the business portion of the city covering an area of one square mile, the stations supplying this territory being three-fifths of a mile from its electrical centre. It is therefore self evident that since such a large portion of the energy supplied is so nearly adjacent to the desirable location of the central station that a direct current distribution system should form the basis of the general system of the company.

It seems to the writer that the useful field of operation for alternating current distribution system is not in large cities but rather in the scattered suburban residence districts and small towns where commercial lighting, elevator service and general power distribution forms an insignificant portion of the demand and where the first cost of the direct current installation would so far exceed that of the alternating current system of distribution with primary mains and large transformers for blocks of lighting as to make the interest charges so great that the property would be rendered unremunerative.

The successful central station company of the future will be, as outlined in my paper read before the Association of Edison Illuminating Companies at its last convention, the one combining intelligently the use of alternating and direct currents, employing direct current in the distribution systems in the thickly settled business and residence districts of a city and alternating current for the distribution systems in the scattered residence districts and surrounding suburbs. The energy will be generated at one or two large condensing stations located where water and fuel may be obtained at the minimum cost and the energy transmitted to the various substations located at the electrical centres of the distribution systems. The choice of low pressure direct current or high pressure alternating current for the transmission to the substations will depend upon their relative distance from the generating stations, rotary transformers or other forms of current rectifiers being employed in the substations which supply the direct current distribution networks when alternating currents are used for the transmission.

Electric Lighting Deal at Chester, Pa.

Ernest H. Davis, general manager of the Lycoming Electric Company, Williamsport, Pa., has purchased a large interest in the business of Beacon Light Company, Chester, Pa., and has been elected a director of the company. Mr. J. George Kaelber, for many years with the Western Electric Company, and well known in electrical circles, is vice-president of the company, and with Mr. Davis will give it his attention. The Beacon Light Company, of Chester, Pa., has purchased and leased the existing electrical interests and controls the city and commercial lighting of Chester and vicinity. Mr. George N. Tidd, former manager and electrical engineer of the Waverly Electric Light and Power Company, has been elected general manager and

electrician of the Beacon Company, and if his past record is any criterion, the success of the company in Chester is assured. Large extensions to the plant are contemplated and many improvements will be made during this season.

TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work—XIV.

BY A. E. DOBBS.

SELECTION OF INSTRUMENTS.

PROBABLY one of the most perplexing questions that the new Exchange management has to face is in regard to the selections of instruments. There are some manufacturers of instruments who are not telephone experts, and in consequence produce instruments that are not perfect by any manner of means; some are fairly good imitators, without possessing the knowledge necessary to successful imitation. They will overlook many important points, but at the same time produce an instrument that is good enough to sell to the inexperienced, and, when, after many months, the buyers' inexperience is succeeded by knowledge he will find that the manufacturers have also learned a thing or two, produced a new form of instrument, and it may be the greenhorn will be caught twice by the same maker. Besides, the newcomer is apt to be caught by low prices, and, I regret to say, competition makes some manufacturers use very inferior material, whereas, successful electrical instruments require correct proportions and good material, and nothing is too good for exchange service. A cheap telephone for exchange work is dear at any price.

Now, this is not to be taken that there are no good telephones made by independent concerns, for there are manufacturers who are doing honest, conscientious work, and trying by every means in their power to produce, and who do produce, as good instruments as are made anywhere, but at the same time purchasers should not always take the first instrument offered them, even under a guarantee, for there are selling agents who will

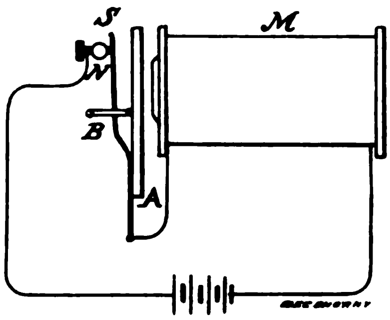

FIG. 43.

give any kind of a guarantee the purchaser may ask for in order to effect a sale; making the guarantee good is another matter.

The independent manufacturers have not yet brought out anything radically new. Their genius seems to have been confined to imitations of Edison and Hunnings which do not possess means of adjustment—which seem to be controlled by patents—and the only adjustment left is to put in more or less carbon until it becomes "about right." If this is carefully done and tests made at the factory, and the carbon is of good quality, there should no further trouble. But in the haste of getting out orders this is not always properly looked after, and many an instrument is condemned after a brief trial on this account. I have remedied the defects in many a transmitter by changing the quantity of carbon granules.

Another point to be noted in this connection is this: Have your instruments and coils as nearly alike as possible and when you have found an instrument that will do your work, take that as standard, and insist that all others shall follow it, unless changes are made to correspond all round. It does not improve the service to have some induction coils wound to 18 or 20 ohms, some to 125 and some to 250 ohms.

We also find buyers who, next to the price, always pay more attention to the outside appearance of an instrument than to its other qualities.

While admitting that the telephone as assembled up to date does not possess the æsthetic qualities one could desire (in fact it could be very materially improved in this respect, and the maker who really succeeds in doing so will score a hit), a utilitarian who has followed up exchange and instrument troubles for two or three years never notices the outside of an instrument at all unless it is a total wreck, his first impulse being to reach down into his pocket for a key and get the box open.

If, upon inspection, the inside shows permanent, substantial work, with contacts that look as though they could be relied upon, with the different circuits properly insulated from each other, with the ringing magnets properly shunted or cut out, and the general appearance indicating that it has been finished by workmen instead of apprentices, he regards these as a good sign.

Then, if, upon test, the receiver, the coils and the transmitter prove all right, he is disposed to accept it, regardless of its outside appearance. But if, on the other hand, he finds contact springs of cheap German silver or brass with weak and unreliable contact pressure, with no platinum anywhere visible, with solder and acid slobbered all around the inside of the box, with magnets looking rusty and cheap, with insulation looking as though it might break down at any time, with bell magnets in series with the talking circuit, and the wiring in such a shape as to be almost impossible of access, he knows that he will have trouble with that instrument from the very start, and no amount of gingerbread work on the outside can possibly redeem it, in his estimation.

I can recall the case of one company having a transmitter which, while new, will show up in fine shape, but in actual use develops troubles of the most aggravating nature, because their instrument wiring is out of reach and seems to have been designed and carried out by boys who were more used to making cheap call bells than anything else.

Suppose we study this question of contact springs. There seems to be an idea that because copper or brass is used in electric light switches and to a great extent in cheap call bells that it will also do for the telephone hook switch, forgetting that the contact on the smallest electric light switches covers several times the area and has many times the pressure of any telephone contacts.

In this connection it may not be amiss to tell a story of an experiment of the author's younger days.

The object of the experiment was to find out how long certain batteries would last on a continuously working circuit, which, however, was lost sight of in the experiments that followed. Not having a bell handy (for bells could not be bought for 20 cents apiece in those days) he made up a coil and magnet of his own, using wire enough to give a resistance of about two ohms. The apparatus, shown in Fig. 43, is crude, of course, but it was good enough for the purpose. The armature (A) was simply an old nail filed down and the spring contact on it (S) was of ordinary brass. The back contact (N) was a wire nail, to which one side of the battery was connected, the armature being pulled back by a rubber band (B), the whole being connected to four cells of battery. Owing to the large size of core used, there was considerable sparking at the contacts between S and N. With this amount of battery there was lively action at the start, but it soon stopped. As the battery did not present a run-down appearance, a search was begun for the cause, when a touch on the armature caused it to start again, only to stop again in a short time. This time an examination was made of the contacts, and it was found that they had blackened considerably. They were rubbed with sandpaper and the rubber band tightened to increase the back pressure, but with the same result as before.

This time there was a change of metals at the contacts and before the experiment was finished about every metal was tried to insure a reliable contact, with the same result, until a piece of carbon took the place of the nail (N) and a piece of silver to the strip (S), after which the service was fairly constant, but even the silver would blacken and cut out after long use, till finally a piece of platinum was secured, which stopped all further trouble, though two pieces of hard carbon would most likely have

worked well also. Now, of course, all contacts do not spark as badly as that one did, but the lesson was well worth learning, and has never been forgotten.

Moral.—See that all contacts have platinum in them, or else that a strong rubbing contact is had, for a strong rubbing contact will clean itself to a limited extent.

Look into one of the latest Bell instruments with, say, a Blake transmitter. Notice that the contacts on the diaphragm are platinum and carbon. The switch hook contacts are platinum altogether, yet even they get dirty once in a while; then notice how the door hinges are connected by a spring with soldered contacts and see how neatly the wiring is all done and how easy of access in case of trouble. Go into a telegraph office and examine the operator's key. There is a hard rubbing contact, yet in standard instruments you will see nothing but platinum points.

Of course, platinum is costly and there are switches made without it that do fairly well, and there are manufacturers who can make as good instruments as the Bell, or even better than the one with the Blake transmitter, and these points are merely mentioned to guide purchasers in their selection.

ELECTRIC TRANSPORTATION

Heavy Underground Electric Railroading Proposed in Paris.

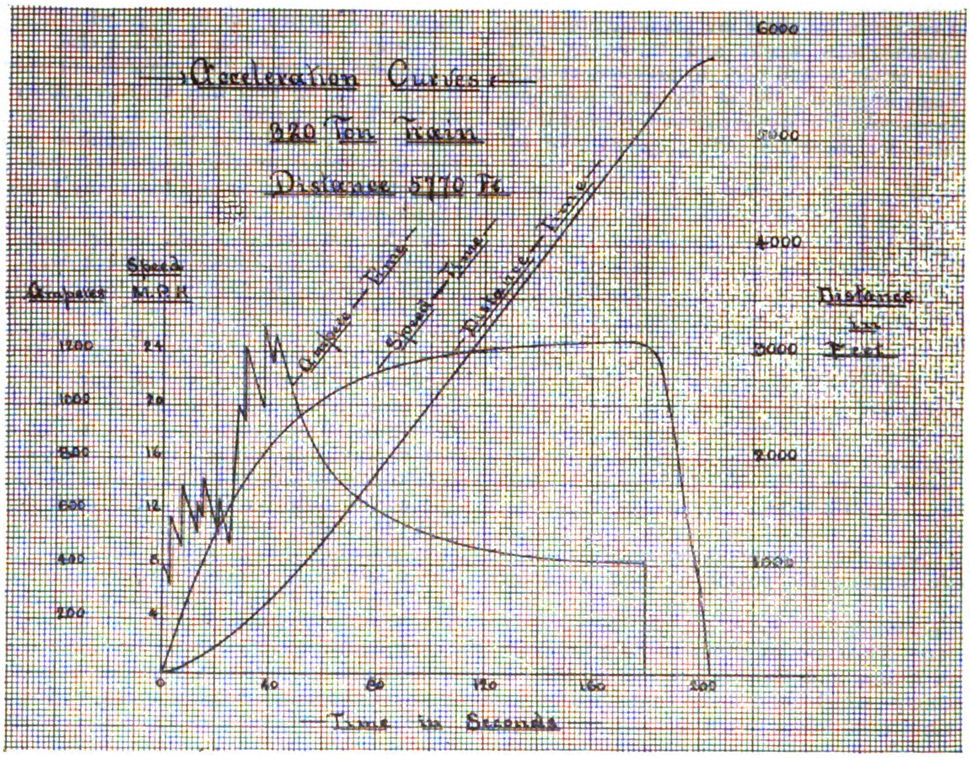
An enterprise involving the expenditure of not less than 40,000,000 francs, or $8,000,000, and the creation of a road, about two and one-half miles long, partly underground, to be operated exclusively by electricity, is about to be undertaken in the city of Paris by the Orleans railroad. The operation of this underground road, as at present contemplated, is to be carried on by means of electric locomotives driven by continuous current at a pressure of between 500 and 700 volts, using the third-rail system of contact. In asking for estimates, however, the company has requested bidders to submit plans also for the use of systems of generation and distribution other than that just mentioned.

The locomotives are to be eight in number, all alike, and able to haul a train of 250 French tons in seven minutes between the station of the Quai d' Orsay and the Pont d'Austerlitz without stopping at the intermediate station of the Pont St. Michel. This means a speed of 45 kilometers an hour. The locomotives should not only be able to haul a train of the weight mentioned on a grade of 11 mm. and on curves of 200 metres radius, but it should also be able to haul trains as heavy as 300 tons at a slower speed. The locomotives must be built to move in either direction, at the same speed, and be of a length to allow them to be turned on turntables 6.2 metres in diameter. They are to be equipped with motor-driven air pump and air brakes.

The electric generating station will be placed at the western end of the Valhubert station departing platform, taking the place of certain waiting rooms. The equipment is to be of sufficient capacity to allow of the simultaneous movement of four 200-ton trains, exclusive of the locomotive, upon the line—one starting from the Austerlitz station, one from the Quai d' Orsay station, the third climbing the grade of 11 m. m. and the fourth running between the Pont St. Michel and the present main station. Furthermore, the generating plant must include sufficient lighting capacity for the three stations already mentioned and the tunnel, as well as for the station and shops at Ivry. The current is to be taken by the locomotives from an insulated third rail at the side of the track in the stations and between the tracks over the rest of the line, due provision being made for all switches and cross-overs.

In order that a better knowledge of the operation of electricity in heavy traction service might be gained than was possible in Europe, the Orleans company recently sent over to America a corps of engineers to investigate the different electric railway installations of this type in this country. The party was headed by H. E. Solacroup, assistant chief engineer of material and traction, and M. Sabouret, the other members being Messrs. Hiberty, Fremenville and Walton. Their inquiries were conducted very quietly, but during their short stay they were able to visit almost every installation of special interest to them in the United States.

A special test was arranged for their benefit at Schenectady on the experimental two-mile track of the General Electric Company, the conditions of the track and load being, as far as possible, similar to those which will obtain on the line in Paris. A length of track was marked off 1.11 of a mile long by two white flags corresponding to the distance between the Quai d' Orsay



ACCELERATION CURVES, SPECIAL TRAIN RUN, SCHENECTADY, N. Y.

and the Pont St. Michel stations, the most difficult portion of the proposed Orleans extension. According to the time schedule arranged for the operation of the road, this distance should be covered in three minutes and fifty seconds. A train was made up of a motor car of the Nantasket Beach pattern, equipped with four General Electric 55-175 h. p. motors as locomotives, several New York Central coaches and seven flat cars loaded with pig iron, making a total train load of 320 tons, including the motor car, which weighed 45 tons. The run between the flags, including starting and stopping, was made easily in three minutes and twenty-five seconds, giving a margin of not less than twenty-five seconds to the good. The diagram on page 680 shows the acceleration curves of this run.

The question of rendering the third rail innocuous after the passage of the train having been brought up, the General Electric Company arranged an exhibition of its method of effecting this result. A section of the third rail was measured off and divided into sections in lengths varying from 30 feet to 500 feet. Connections were made between these and a system of automatic switches, and the conditions of the General Electric system of surface contact, almost exactly reproduced. By this system the arrangement of circuits is such that the sections into which the rail is divided may be of any length from that of a few feet to any number of miles, that is, any section of the conductor rail will be alive only when the train itself is running over that section. The instant the train passes to the succeeding section, that which it has just left becomes dead and absolutely innocuous. The use of this system also renders it possible to "section" the conducting rail at stations, leaving it continuously alive at all intermediate points. The switch cutting the dead section into circuit is closed as the contact shoe of the train comes into contact with the conductor, energizing it, and is automatically opened as the train passes to the next dead section.

The motor car was run over that part of the track beside which the third rail was sectioned, and as a visual means of indicating that the third rail was alive a number of incandescent lamps on the top of the boxes containing the switches were connected to the conductor. As the car reached the sections and rendered them alive, the lamps lighted up, being extinguished as the contact shoes passed over the dividing lines between the different sections.

These tests formed the subject of the concluding investigations of the French engineers in this country. A few days before their departure a dinner was tendered to them at Delmonico's, at which many prominent railroad engineers and electricians were present to meet them. They admitted having received many new ideas during their stay, and returned to France convinced of the use and possibilities of electricity as a motive power, especially in the field of heavy traction.

LETTERS TO THE EDITOR

Condict Series Multiple Controller Patent.

THE sustaining of the Condict patent on the series-multiple controller by Judge Townsend was undoubtedly a just and proper decision, and will be a most valuable asset to the General Electric Company and the Electric Car Company. The status of this matter is perhaps not fully known, and as it might be interesting to others outside of the railway car builders, I would make the following explanations:

The Hunter Electric Company in 1887 made a number of these series-multiple controller switches under the broad inventions of myself, the first of which did not use the resistance outside of employing the sectional windings or fields for this purpose. These features are all covered in patents granted to me, the broad series-multiple controller patent being No. 385,055, June 26, 1888. Another broad patent is 494,705, April 4, 1893. This company was organized by me under my electric railway inventions, and Mr. Condict was employed as superintendent at our works. Owing to the large current used the contacts were more or less heated, with danger of fusing, when the controller was moved slowly. To improve this, Mr. Condict, in connection with my work, added the supplementary resistance to overcome this danger and at the same time increase the possible regulation. The improvement was undoubtedly an excellent one, and, while specific, has proved to be universally approved and is used with very little modification on all controllers.

When the Hunter Electric Company later became known as the Electric Car Company of America, this became the standard form of the Hunter series-multiple controller. The Thomson-Houston Electric Company purchased from the Electric Car Company of America the exclusive license to all of the patents and inventions which it controlled (amounting to very large numbers), and among which was the particular Condict patent, upon which the court has recently rendered a decision.

R. M. HUNTER.

Philadelphia, May 26, 1898.

Fan Motors for Railroad Cars.

I AM always interested in the suggestions made from time to time in your editorial columns as to the uses to which electricity can be put. Since the coming of the warm weather I have noted the ever widening range of usefulness forecast for the fan motor. A journey last year from New York City to the terminus of the New York Central railroad, en route to the Adirondacks, where I hoped to find the fresh air and quiet denied the denizens of large cities, was almost unbearable on account of the heat and foul air. In order to prevent a completion of the broiling and stifling process, the windows were of necessity opened, and, although carefully screened, the indraught of dust and cinders that followed increased physical discomfort to such a point that endurance seemed no longer possible. At the end of the railway journey, in common with my fellow travelers, I was in a condition of utter exhaustion and nerve irritability. During the long, weary hours of the day, when St. Lawrence's position on his gridiron seemed an enviable one, I cast about in my mind for some device which would make summer traveling tolerable. Electric fans suitably placed immediately suggested themselves as a solution of the problem. Involuntarily my fingers sought the magic button and as in imagination I felt the cooling breezes, I determined to give the thought to the Engineer for dissemination. Storage batteries of requisite ampere hours could be utilized as a source of e. m. f. They could be exchanged for freshly charged accumulators at necessary points along the line.

Nothing would invite to summer travel as the equipment of the passenger coaches of the railways throughout the length and breadth of the land with efficient fan motors. In this way the annoyance of hot, foul and dust-laden air would be avoided.

If, in addition, upholstered seats could be universally replaced with those of wicker or rattan, the invalid and those who do not bear well the discomforts of travel would find it a temptation to escape from the heat and turmoil of the city to the cool and quiet retreats of mountain and sea.

MARGARET A. CLEAVES.

New York City.

LITERATURE

THE 1898 EDITION OF "THE MINERAL INDUSTRY."

The well-known annual entitled "The Mineral Industry," which will soon appear for the sixth time, will contain complete statistics of the mineral and metal production of the United States in 1897, collected with infinite labor and care, and at much expense. The mineral and metal productions of the United States in 1897 here recorded were the largest in the history of this or any other country. They almost equal in value the production of all Europe. The economic details published in "The Mineral Industry" volume show that the United States is rapidly attaining the point where it will be the greatest exporter of minerals and metals of all the commercial nations. The editor, R. P. Rothwell, C. E., M. E., and the "Engineering and Mining Journal," are to be congratulated on this admirable production.

Vol. XXV. NEW YORK, JUNE 16, 1898. No. 528.

Notes on the Chicago Electric Light Convention.

THE Chicago convention has come and gone, and while there has been larger attendance, we cannot in any instance recall a larger number of listeners to the papers read, or more earnest discussions. By stating that the number of attendants was not so great, we do not mean to imply that there was a smaller number of central station men than usual. On the contrary, they exceeded in number those at many previous conventions, the smallness in the aggregate number being due to the absence of many of the supply men who have heretofore served to brighten conventions with their presence.

It was understood from the start that President Insull intended this convention to do convention business first, and other things afterwards, or not at all—and this programme was strictly adhered to. The consequence was that at no time during the entire proceedings of three days were there less than two hundred auditors in their seats, while at times, the large Banquet Hall of the Auditorium Hotel, seating four hundred, was filled to its utmost capacity. This is a most remarkable manifestation of continued interest in the work of the association.

The main features of the convention work may be considered to have been municipal ownership, and the alternating vs. the direct current. Who would have supposed that the latter, almost forgotten, topic would have occupied a whole day of the convention's time, claiming two sessions and being perforce curtailed for lack of time. Yet such was the fact. The gauntlet was thrown down by Mr. Wagner who stood as the champion of the alternating current, and more particularly for the single-phase alternating current. His case was well presented, and the figures contained in his paper were well marshalled. Mr. Ferguson's paper, on "General Distribution from Central Station by Direct Current," although not designed to be a reply to Mr. Wagner, nevertheless, served that purpose very fully. After the reading of the papers a battle royal began which, as stated before, lasted all day. We rather opine that the direct current advocates had a little better of the argument, or rather that they had more facts and figures available to fortify them than their opponent. Still it may be fairly said that the battle was a drawn one, and that, judging from the expression of opinion in various quarters, the standard system of distribution of the future will be neither exclusively alternating nor direct, but a judicious mixture of both.

During the course of the discussion one or two points were touched on, which we think might well be brought home in these days of increasing power applications. We have heard, for example, that, as a rule, elevator work does not pay, owing to the suddenness with which the current demand comes on the circuits and the heavy drain and drop of the potential necessarily affecting the circuit. As was pointed out by Mr. Dow, elevator work was not to be despised, or rejected as an inconvenient load to the station, if for no other reason than that to reject such service was a direct incentive to the installation of private plants, which must in the end detract largely from the field of operation of the central station. It was evident if the owner of a building was forced to put in an elevator plant himself, he would employ an engineer, who could very easily look after an electric light plant at the same time. This is a very important point in our estimation, and will no doubt be acted upon.

As to municipal ownership, Mr. Dow's paper put the case very clearly indeed. He took for his text the experience of Detroit, and indeed no better example could have been chosen, if the author had wished to demonstrate the evil effects of useless competition for city lighting contracts; but in addition to that Mr. Dow analyzed the subject independently, and arrived at a number of conclusions. We are not prepared to agree entirely with all of these, but most of them are eminently practical, and some of them contain suggestions which are well worth considering and which may serve to stem the tide which now seems to threaten many central station properties. We shall print the paper in full with others on the subject. Throughout the discussion of Mr. Dow's paper there was noticeable an unmistakable undercurrent of opinion that much of the hardship to which many electric lighting companies have been subjected in the past, has been brought on either by their own carelessness, their inequitable dealings with the public, and by bad service. It would be well, therefore, to keep in sight the experience of such companies. It seemed to be generally admitted that the public, as a rule, is disposed to treat electric light companies fairly, but that it requires to be educated in order to appreciate the stand which the companies take on municipal ownership. It was generally conceded, too, that the association acting as a body could do much to aid individual members, and that while a campaign against municipal ownership might prove arduous and expensive to any one company, the association if properly supported by its members could accomplish a vast deal of good at a small expense to the individual members.

There is another point which for the good of the whole industry we deem deserving of especial attention, and that is the

suggestions that the companies get together and lay down a schedule for establishing a uniform system of keeping accounts, similar to that required by the Board of Trade for the English electric lighting companies. This point was well brought out in the paper read by Mr. Calvin W. Rice, whose analysis of the cost of the generation and distribution of a unit of electricity, we are grieved to say, was based almost entirely on English and continental European figures. One other point brought out in Mr. Rice's paper was the fact that the cost per unit of our railway plants was better than that of any English lighting station. We believe that the incoming president of the association can do the association no greater service than to set on foot the carrying out of the plan of having all members of the association tabulate their station statistics in a uniform manner. Why wait until forced to do so by a State Commission? And that brings us to the sentiment also expressed on the floor of the convention that State commissions governing gas and electric companies would be one of the surest means of curing the municipal ownership craze. In private conversation, delegates from Massachusetts, one and all praised the work of their State commission whom they looked to as their bulwark against unwarranted attack from every quarter. While this is a subject which might be the particular work of the State associations, the N. E. L. A. may well imitate the movement for the common good.

In conclusion we must felicitate Mr. Insull on the success of his administration and on the zeal with which the duties of his office have been discharged. The association exists to discharge very important functions, and these Mr. Insull has carried out, in some respects quietly and witn reserve, but none the less effectively. He hands the association over to his successor in admirable shape, secure on firm foundations; and all wish and expect for President Young a prosperous and useful term of office at the head of one of the most responsible and serviceable electrical bodies in the world.

The Study of Foreign Methods.

AN interesting exemplification of modern business methods is presented by the Special Commission that is to be sent abroad by the Edison Electric Illuminating Company, of New York, for the purpose of reporting on the methods in use in Europe for the generation, distribution and sale of current. The commission, which leaves in a few days, is composed of Mr. J. W. Lieb, Jr., general manager, Mr. J. Van Vleck, constructing engineer, and Mr. Arthur Williams, general inspector. It will be seen that these gentlemen represent the company in its various functions as an electricity supply concern, and that their reports, each supplementing the others, should cover thoroughly the whole field of operation, as related to the art and to the public. The commission will visit stations in England, Italy, Germany, etc., including those at London, Paris, Milan, Rome, Berlin, Hamburg, Vienna and Buda Pest, and may also go as far north as Stockholm. The enterprise of the Edison Co. is to be heartily commended, and is in line with the progressive tendencies that have always marked its work. We have been glad to note, moreover, the visit of English and foreign engineers to this country in increasing numbers of late to study American central station practice. This reciprocity is of the right kind and should be encouraged. There will always remain abundant reasons for diverging practice, but there are equally a number of important features of the work which can be made uniform through all countries, with manifest gain in the development and perfection of the art.

The Validity of City Contracts.

ONE of the most interesting passages of President Insull's weighty and memorable address in Chicago last week was that dealing with the question of public franchises, and advocating that the best protection for investment was an exclusive grant under proper conditions of control. The positions taken by Mr. Insull seem to us impregnable, as arguments for good service cheaply done. But there is a further point which we regard as coming within the lines of that part of his address. We refer to the frequent repudiation of contracts by city bodies after the local companies have, so to speak, staked their all in putting up plant to meet the requirements. This is an evil that must be grappled with. A case of the kind has just occurred at Houston, Texas.

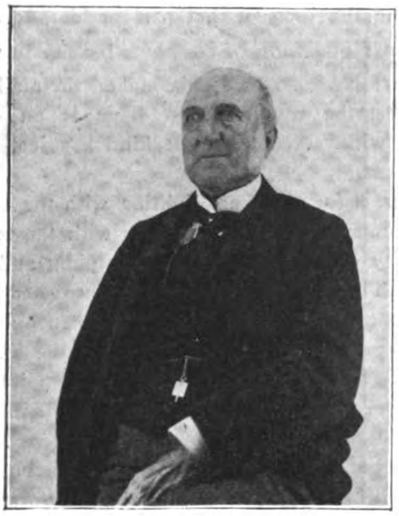
The city made a contract for ten years lighting with the Citizens' Electric Light Company, in 1894, and now with the term not half expired, the city wants to put in its own plant and to abrogate its contract. The City Attorney has furnished an opinion to the effect that he "does not think there can be any danger of the city being compelled to comply with the terms of this contract." He recites a number of cases, the point in each being that the city council has not the authority to make a contract for lighting the city in such a way as to prevent later councils from "carrying out the expressed will of the inhabitants of the municipality as to different and to them a better way of supplying lights to the city." One wonders what a contract is worth, anyhow! There is no question raised of fraud and none as to the service itself, but the whole argument is that the city has changed its mind and has a right to tear up its contracts every time a new city council is elected. We refuse to believe that such things are permitted under a right construction of the law. The implication and the possibilities of wrong to innocent people are too outrageous. We may note that one of the incidental arguments of the City Attorney is that the contract "is not binding because it is exclusive in its nature, and in the light of our decisions a monopoly and void."

It seems to us that here is a matter in which the members of the National Electric Light Association might well make common cause. If contracts are to be torn up whenever the municipal plant fever strikes a town, or for any other reason, it is time local companies knew it and made a new fight for the sacredness of contracts under the law of the land.

WE are glad to note that Dr. Louis Duncan has been gazetted a Major in the new U. S. Volunteer Engineer Corps, and Lieut. E. B. Ives as a Captain. Good service may well be expected from these gentlemen, so well known in the field of electrical engineering, and both of whom have enjoyed professional training either at Annapolis or at West Point. Of the electrical men already active in the war, good news comes of gallant work, particularly of those on board the Yankee, to which Lieut. S. Dana Greene was assigned with part of the Naval Reserve. The boys put up a splendid fight at the bombardment of Santiago the other day, and their behavior won the enthusiastic commendation of the whole fleet.

AS this issue of The Electrical Engineer goes to press, the President is expected to sign the bill providing for war taxation. Under this measure, each telegram will be taxed one cent and each extra territorial or long-distance telephone message one cent. It is estimated that these two items will yield an income of about $700,000 a year, which will about pay for one day's good fighting.

Closing Notes on the Exhibition.



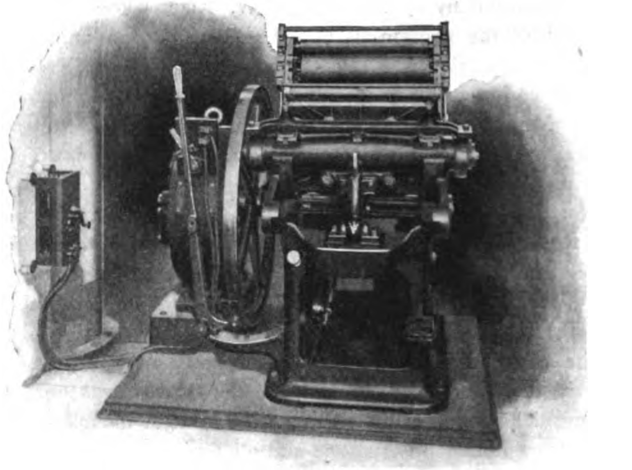
HON. CHAUNCEY M. DEPEW.
(Photographed by light of Moore Vacuum tubes.)

BEFORE the Electrical Exhibition at Madison Square Garden closed, the Moore chapel was visited by a number of celebrities, and among them was the Hon. Chauncey M. Depew, prior to his departure for England. While in the chapel he was photographed by the light of the Moore vacuum tubes. One of the pictures thus taken instantaneously is here reproduced, and will be recognized as a singularly faithful photograph of the "Grand Old Man of the Grand Central." After the photograph had been taken the public was admitted to the chapel and there another photograph was taken with success. Mr. Moore expressed the opinion that in future the vacuum tube would take the place of the flashlight and be far more agreeable to the victim. But the great immediate gain was the ability to secure a vacuum tube photograph instantaneously instead of in five minutes or several seconds at the best.

The amount of literature distributed at the exhibition was something prodigious. Thousands of copies of The Electrical Engineer were given away, and the other electrical journals were also free-handed in their distribution. At the Moore chapel literal hundreds of thousands of descriptive sheets were handed out, and tons of circulars were used by such concerns as the Electrical Engineer Institute of Correspondence Instruction, the New York Telephone Company, Elmer P. Morris, the Walker Company, the New York Electrical Society, the De La Vergne Refrigerating Company, Monarch Manufacturing Company, Diesel Motor Company and others. The Crocker-Wheeler Electric Company, for example, distributed no fewer than 25,000 copies of their handsome special bulletins, each number of which is a valuable special treatise on some branch of the electrical art. The literature of the New York Telephone Company deserves a special word of high commendation. It was very pretty and tasteful, was pithy and to the point and was so handy that it was always carried away and preserved by the recipient. The New York Edison Company also made a judicious distribution of literature relative to the various uses of current in the office and home.

Electric Printing at the Exhibition.

ONE of the most striking exhibits at the Electrical Exhibition was that made by the John Thomson Press Co., of this city, of one of their beautiful "half medium" Colt's Armory presses, style No. 2, driven by a Bullock direct connected motor at speeds of from 20 to 40 impressions a minute, or say 1,200 an hour, as operated at the show. We present here a picture of the exhibit, which was one of the features of the opening night, and which remained in operation through the month. The quality of the work done on the press was a matter of surprise to visitors who had not before seen it. On the opening and subsequent nights it ran off several thousands of the Postal Telegraph blanks, recording the work then done. This was followed up by a splendid Bartlett half-tone of Chief Engineer Melville, of the Navy, and by the famous Schussele-Sartain engraving of the "Iron Worker and King Solomon." But perhaps the chief hit was made with another exquisite Bartlett half-tone of Admiral Dewey. These various blocks were printed on plate paper, and were handed out as souvenirs of the exhibition, being sought



JOHN THOMSON PRESS AND BULLOCK MOTOR AT THE EXHIBITION.

after most eagerly, not only for their interest, but as choice specimens of the printing art. That the work was done with the aid of the electric motor speaks volumes for the smoothness of the running of the apparatus employed.

Habirshaw Wires and Cables at the Exhibition.

A VERY neat and quietly tasteful exhibit at the Electrical Exposition, just closed at Madison Square Garden, was that of the India Rubber and Gutta Percha Insulating Company, who had a space just to the left of the entrance, on the main floor, on the aisle between the Edison exhibit and that of the New York Telephone Company. The front of the space was occupied by a large show case entirely of plate glass, and a notable feature of the contents was the fact that all the samples exhibited were from actual orders and goods shipped. One conspic-

EXHIBIT OF THE INDIA RUBBER AND GUTTA PERCHA INSULATING CO.

uous item among the many Habirshaw specialties was a complete assortment of Niagara power-house bus-bars, which have been described already in The Engineer, and which are heavy copper tubes specially insulated. There were also regular cables of 500,000 c. m. to carry 20,000 volt current and a concentric three-conductor cable, each of 1,000,000 c. m. Samples were also shown of the 4,000,000 c. m. cable used in the Siegel-Cooper "Big Store," and of the large cables furnished for the Waldorf-Astoria plant, and for the new Delmonico. A variety of ordi-

nary cables, submarine cables, cables for torpedo work, and wires and cables for interior use, rounded out a most interesting exhibit that was closely studied by the expert and greatly admired by the general public. Messrs. Godfrey, Harrington and Olson were in constant attendance and Dr. Habirshaw himself paid the exhibition some visits with friends. While not large, the exhibit was so judiciously selected as to exemplify the widest range in electrical wire and cable manufacture.

Souvenirs Given Away at the New York Electrical Exhibition.

PERHAPS one of the most substantial evidences of the good will of the electrical fraternity towards those who patronize it or take an interest in its products, was the liberality displayed at the recent show in giving away valuable and useful souvenirs to visitors. Among these souvenirs should be mentioned the one-foot folding celluloid rulers of the Electric Storage Battery Company; the handsome buttons announcing that you had paid a visit to A. K. Warren and Company; a spirit level by the Borne Scrymser Co.; porcelain pin holders full of points on the products of the Peru Electric Manufacturing Company; miniature triple-petticoat insulators distributed by R. Thomas & Sons Company; nickel-plated drills in the form of watch charms by the Cleveland Twist Drill Company; wire charts and five dollar bills by Elmer P. Morris and the Adams-Bagnall Electric Company; the card board safety guns by the Safety Insulated Wire Company, as harmless as the miniature vacuum tubes distributed in the Moore Chapel; ebonite paper cutters, the gift of the Crown Woven Wire Brush Company; electrical periodicals which were much sought after, and useful note books given away by the enterprising New York Telephone Company, and handkerchiefs with name embroidered for a very small sum of money. Tea and biscuits, and strawberry short cake were dispensed in

THE NILES TOOL WORKS CO.'S EXHIBIT.

the Edison booth, catalogues and knowledge were given away gratis by everybody, and broken fingers, faces disfigured by X-rays, and other features not on the daily programme will ever remain fresh in the minds of the unfortunate victims as some souvenirs of the second New York electrical exhibition.

THE PHILADELPHIA ELECTRICAL EXHIBITION.

JUNE 6 TO JULY 6.

Opening the Exhibition.

WITH impressive ceremonies the Philadelphia Electrical Exhibition was formally opened to the public on Monday, June 6. For months the promoters of this enterprise had been diligently at work devising novel decorative effects and arranging special features, as well as seeking to demonstrate the limitless applications of the electric current. The approbation expressed by those who attended the opening exercises and the large audiences which have visited the exhibition during the past week were certainly convincing evidence that the efforts of the promoters had been crowned with success and that the show has come up to the expectations of Prof. W. D. Marks and its other promoters.

The exterior of the building at 818 and 820 Chestnut street, within which the exhibition is held, presents a very beautiful and dazzling appearance at night. The whole front of the building is ablaze with 61 Helios enclosed arc lamps, and immediately above the entrance is a large American flag, in flashing incandescent lamps. By the use of a commutator the lights are made to alternate in such a way that only every second lamp emits a light, but the change is so rapid and regular that the effect obtained is that of a flag gently waving in the breeze. In the window to the right of the main entrance is an American escutcheon outlined in miniature incandescent lamps, surmounted by a large eagle with spread wings. In the window to the left of the entrance is a windmill with revolving blades studded with colored miniature incandescent lamps. The interior of the building has been beautified by a lavish display of bunting draped on ceiling, pillars and walls, while all about the nooks and corners, where mirrors abound, are banks and festoons of flowers. Crowning the whole scheme of illumination are the individual displays in fanciful designs that mark the rivalry of the exhibitors.

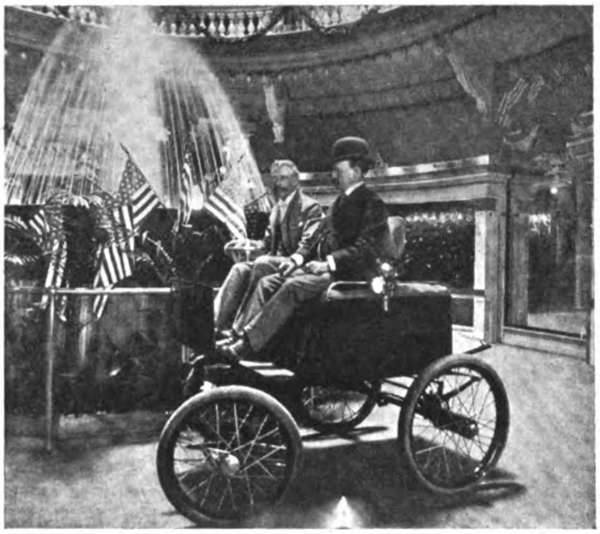
There are many interesting novelties shown at the exhibition. One of these is an electric fountain in the rotunda, shown in the illustration, which can be best seen from the gallery overhead. Multi-colored lamps set on a revolving horizontal table beneath the jetting water are switched on and off as they are set in motion producing a kaleidoscopic effect which is very pretty. Around the rotunda, on each side of the large mirrors, are four large panels, trimmed with natural plants, 500 fresh roses being used for this decoration every day. In order to preserve the roses for this brief period, each rose is placed in a small glass tube filled with water which is then slipped among the foliage interspersed with numerous incandescent lamps. The dome of the rotunda has two frescoes painted upon it, one representing the westward march of empire, the other the landing of Columbus. Carefully considering the patriotic feeling of the visitors the managers obliterated all traces of the Spanish standard which Columbus bore proudly aloft, by fastening an American flag over it, giving the worthy navigator the appearance of a traitor to his country. Around the rotunda are numerous incandescent lamps surrounded by holophane globes of varied colors, and on the gallery the First Regiment Band is seated, discoursing music every afternoon and evening. Another striking decorative feature on the main floor is a peacock of normal size in all its natural iridescence. The great tail is fully spread and on each feather sparkles a miniature light of the appropriate hue. In sharp contrast to this is a picture of a more sombre character. It is a full rigged ship, set in a frame, steadily making its way over the sea, under the light of the moon and of hundreds of stars. The ship tosses and moves, the waves rise and fall creating a very realistic impression. A number of novel effects in revolving lights are also shown which not alone attract but hold the attention of the spectators.

Another novel feature is an electrical cataract to which the whole of the second floor front is given over. It is an importation from Paris with elaborations by American genius. Upon a sheet of water falling through a distance of ten feet amidst beautiful scenery, pictures of flowers, statuary, flags, and pictures of naval and military heroes are projected and these stand out as though carved or painted in bold relief. Beautiful color effects are produced by slides operated by Mr. M. F. Oebbecke, who is in charge of the apparatus. Other features of interest, outside of the commercial exhibits which will be described later, are the X-ray exhibit, the Moore Turkish smoking room, the kinematograph war pictures and the Edison phonograph

exhibit, all on the second floor, and the Edison ore separation model, the Hunter exhibit and the welding machine in operation on the main floor. All these features and the general harmonious arrangement of the details reflect great credit on Prof. Wm. D. Marks, the director, Arthur Falkenau, consulting engineer, A. A. Lowry, treasurer, Guy King, architect, Arthur Organ, superintendent and W. Bartine, the electrical engineer.

The Kennedy Carriage at the Philadelphia Exhibition.

ONE of the most interesting features shown at the Philadelphia Electrical Exhibition and one which is attracting considerable attention, is the handsome electrically propelled vehicle exhibited by Messrs. C. W. Kennedy, F. A. Pocock and Ralph



THE KENNEDY CARRIAGE AND THE ELECTRIC FOUNTAIN AT THE EXHIBITION.

Ashley. The carriage is in constant operation in the exhibition hall, and has won the admiration of all by its ease of running, light construction and perfect control of speed and direction. Our illustration shows the carriage in front of the electric fountain, around which it makes its circuit many times during the day, to the delight of those who have the good fortune of being the occupants. The outfit embodies so many new and distinct features that a detailed description of its mechanical construction, the motor and the batteries, must certainly be of interest.

The wheels in front are 28 inches in diameter and 32 inches at the rear, and are equipped with Hartford single tube tires. A solid shaft, 1½ inches square, for the rear support, carries the rear wheels at each end, mounted upon the Rubber Tire Wheel Company's roller bearings, giving very low friction and a great length of surface, whilst they are dustproof. The rear springs are bolted solid onto this shaft, the rear upper ends being bolted to the frame and the front end being connected by a cross spring, which supports the battery weight exactly in its centre and distributes the load to a steel angle to both sides of the frame. The front wheels are made to do all the work, both steering and turning, in the lighter vehicles. The front wheels, again, support the machine by a 1½ inch diameter steel shaft, which is not broken by hinges or a differential gear, but runs right through both hubs, giving great strength to all the running gear.

The right-hand wheel is keyed to the shaft, which runs in two Mossberg-Granville roller bearings of ample length. The end thrust is taken up by three sets of ball bearings, one set outside each of the roller bearings and one set outside of the loose left-hand wheel. The bearing blocks are distanced and lined by a steel tube and carry the front springs, which are firmly held by one through bolt and are belted to the steering frame at the top of the springs. To the left of the left ball thrust the bevel gear of the differential is keyed to the shaft; the jack runs loose on the shaft with its large gear and four bevels. These transmit the power to the shaft through the bevel keyed to it and to the left wheel through a bevel belted to its hub. On the outside of this wheel is another ball thrust.

The steering frame is in this way connected directly with the front wheels, and the king bolt, which is situated far behind the axle, is a roller bearing. On this frame are three roller bearings, which support the main frame. By main frame for any class of work is meant the top of the gear, as applied of late to carriages. Anything that is put above this is a superstructure, and may be a delivery wagon or surrey. The running gear is completed up to this point. The king bolt being far behind the axle makes the body of this machine very light, and its tendency on the road is to go straight ahead. The driving of the front wheels allows the motor full power to lift the machine out of any hole it may get into, and at the same time to steer that wheel away from the least obstruction. The carriage also does not "weave," as the rear steering machines do. None of the ball bearings used in this machine are under pressure, all rollers and balls being only used for thrust.

THE MOTOR.—The motor is of the multipolar type, with a double armature and no external resistance. The speed and power of the motor is controlled entirely by different combinations of field and armature coils, which allow of a range of from two to eighteen miles per hour on the level. The power of the motor is in proportion to its speed, as in all series motors. The steering and control of such a combination is very nearly perfect, as demonstrated by the carriage in operation at the exhibition. The cells are always connected in series, and the full pressure of 44 cells is used with all combinations.

THE BATTERY.—The batteries are of special design of the Planté type. They consist of rubber trays one inch deep, with flaring sides set one within the other. The plates, which are lying at the bottom of each tray, are covered with sand, so as to preserve them in the proper position. Among the numerous advantages of these cells may be mentioned the small space they occupy; no possibility of buckling; large area of surface exposed; extraordinarily heavy charge and discharge rates; no slopping of the acid, and small weight. The entire combination makes a very light and easy-running machine, which can be turned almost within its own length. The same frame may be applied to delivery wagons or wagons for heavy traffic. The entire carriage weighs about 1,400 pounds, and with one charge of the battery 30 to 40 miles can be covered on good roads. With a heavier battery a range up to 100 miles on one charge can be obtained.

Mr. C. W. Kennedy has been in the electrical business in its various applied branches for 30 years and is well known to the members of the profession. He began as a train dispatcher and for a number of years was engaged in telephone work, being one of the old-timers, together with Edison, Delany, Catlin and others. He then devoted himself to railroad work and general engineering, and is now interested in the development of motors, storage batteries and automobiles for any kind of power.

Mr. F. A. Pocock, designer of the vehicle, will be remembered as the representative of the Thomson-Houston company when they started in the mining business, being a mining engineer by profession. The work put in by him at the Erie colliery near Scranton is still in active operation. This led to the Blossberg Coal Company's plant, for which he designed and built the "terrapin back" mining locomotive for the General Electric Company, he being at that time the consulting engineer for the mining department under Captain Griffin. The pumping plants put in around Scranton for the Pancast Coal Company, the Hillside Coal Company, the Connell Coal Company, which was the first mining pump on wheels built by the Gould company, Seneca Falls, N. Y., and equipped with T. H. motor, was followed by a larger pump in the Woodward colliery of the Delaware, Lackawanna & Western. Mr. Pocock then went back to mining work, built the plant of the Chamberville Coal Company, Pottsville, Pa., and two and a half years ago joined Mr. Kennedy in the electrical business.

Mr. R. Ashley, the electrician of this combination, is a self-made electrical engineer of wide experience. He has been associated with Mr. Kennedy for a number of years and has built for him two very efficient electric launches, 31 and 25 feet long, respectively, which have been in successful operation for over a year. The office of the company is located at 44 North Fourth street, Philadelphia, Pa.

A VERY COSY AND CONSPICUOUS space has been reserved on the main floor for the electrical journals, who at once took possession of "Newspaper Row" and are distributing and selling their respective periodicals as well as making the space their headquarters and a rendezvous for their friends.

Wilday Engraving Exhibit.

A very interesting exhibit is that of J. H. Wilday, 23 Duane street, New York, who has on exhibition and in operation one of his well known electric engraving machines with which he engraves on numerous articles on exhibition names or initials or special designs and patriotic emblems. In order to introduce this interesting machine Mr. Wilday offers to send a silver match safe with name engraved for 25 cents to any one who will send an order to the above office.

The Exhibit of The Edison Electric Light Co. of Philadelphia.

THE advantages of the liberal use of electricity for light and power are clearly demonstrated at the booth of the Edison Electric Light Company, of Philadelphia, illustrated herewith, which occupies a conspicuous place in the centre of the building. This company supplies all current furnished the exhibition building and the exhibitors. The methods of lighting shown are both artistic and practical. The sign work is displayed on the arch of the booth. The ordinary lighting is shown by every style of Edison lamp manufactured, exemplifying the difference in finish, shape, candle power and color. The working of the heating apparatus is not the least interesting. Cooking, ironing and heating are done before one's eyes. The fans exhibited at the Edison booth are as refreshing as they are novel and interesting; almost every style is shown, including the bracket fan, which has become quite a favorite.

The numerous styles of circuit breakers are both interesting

JOINT EXHIBIT OF THE EDISON AND BRUSH ELECTRIC LIGHT COMPANIES, OF PHILADELPHIA.

and instructive, and prove conclusively that the practical man of to-day is aware of the fact that "an ounce of prevention is worth more than a pound of cure."

The use of motors for practical shop work is shown here to advantage. The printing press and lathe shown at the Edison booth are doing every-day work; in fact, the press is turning out the literature that the company is distributing.

The meters shown are styles in every-day use by the Edison company—chemical and wattmeters. They are connected with a bank of lamps which are under control of a series of switches, clearly demonstrating the accuracy and reliability of these meters. The exhibit is always surrounded by a large number of interested visitors, and Mr. T. G. Seixas, the manager of the company, and a corps of assistants are kept busy answering the numerous questions asked.

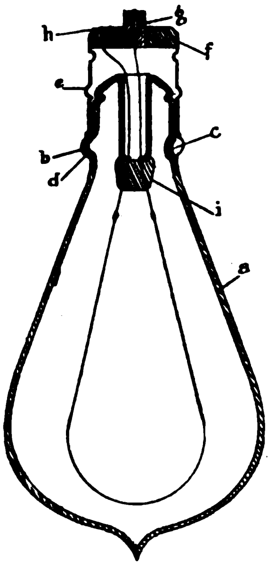
In a Taunton Tack Factory.

Among the prominent manufacturing firms recently adopting electricity for shop power is the Atlas Tack Company, of Taunton, Mass. A 150 k. w., 440 volt, 3,000 alternations Westinghouse three-phase generator has been installed, together with nine of the Westinghouse type "C" motors, for the operation of three large tack mills, extending for a radius of 1,500 feet about the power plant. The installation of this apparatus will enable the purchasers to shut down two steam plants, to cut out a great deal of long shafting, and to greatly increase the efficiency of the entire plant. Some twenty or thirty additional Westinghouse motors are to be installed in a short time, together with a 1,000-light Westinghouse dynamo.

NEWS AND NOTES

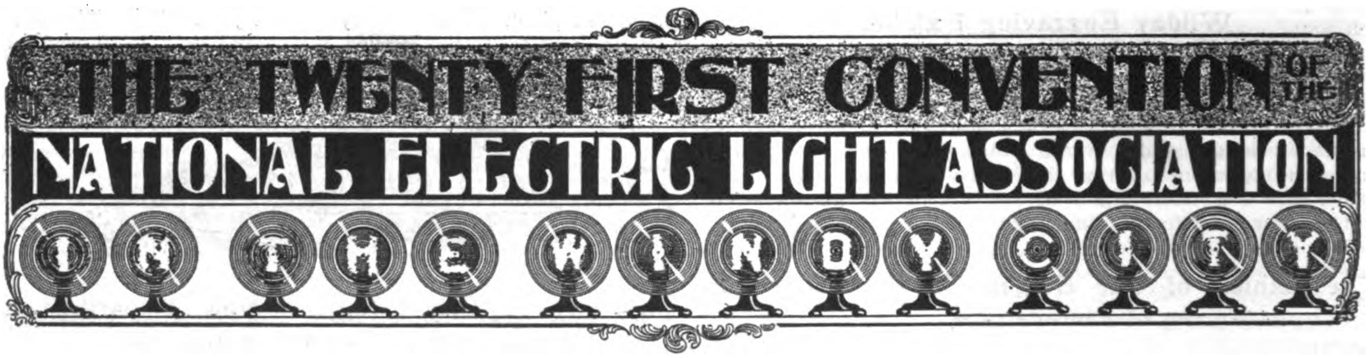
The 20th Century Lamp—A New Departure in Incandescent Lamp Construction.

OF late years so many new and varied styles of incandescent lamps have been placed on the market that volumes could easily be filled with the descriptions of the various types and the details of their construction. What may be considered, however, to be a radical departure from usual methods and one which appears to embody many valuable features, is the lamp manufactured under the Fowler patents by The Twentieth Century Lamp Works, 1031 Walnut street, Philadelphia, Pa., as shown at the exhibition. The main feature of this lamp is the satisfactory method of securing the bulbs in the bases, which will be best understood by reference to the figure below. In this figure the lamp a has on its upper portion an annular projection b with the notch c. Around this projection slips a split brass collar d which has an indentation to fit the projection b and also a small projection which fits in the notch c and pre-



20th CENTURY LAMP.

vents the collar from turning. Around this collar, which has an outward springing tendency, is slipped the base e which may be of any one of the standard styles. The upper portion of this base is closed by a porcelain disc f with a brass tip g in the centre to which one of the terminals is soldered, the other terminal being soldered to the base e at h. The leading-in wires are fused into a glass projection i in the usual manner. A drop of solder mechanically joins the collar d with the base e and prevents the latter from turning. This method, as will be seen, does away with the use of plaster of paris, making a mechanically strong lamp and one that will not work loose in the base, neither will it soak up or hold moisture which by electrolytic action eats away the inleading wires and short circuits the lamp in the base. In addition, these lamps have interchangeable bases and are especially adapted to street lighting, sign work, for use in damp places, and in places where lamps are roughly handled. The lamps are of very high efficiency and long life, with least decrease in candle power. The company have already received large orders for these lamps and those furnished have given entire satisfaction. Mr. G. M. DeGinther is manager of the company, and is a well known dealer in electrical supplies and novelties in Philadelphia.



Twenty-First Convention of the National Electric Light Association, Chicago, June 7, 8 and 9, 1898.

THE twenty-first convention of the National Electric Light Association was called to order at 11 a. m. at the Auditorium Hotel, Chicago, on June 7, by President Insull, who read the address printed elsewhere in this issue.[1]

Invitations and courtesies of various kinds were announced, including the free use of special telephones placed in the secretary's office by the Chicago and Long Distance Telephone companies.

Mr. Calvin W. Rice, of Brooklyn, then read a paper on the "Cost of the Generation and Distribution of a Unit of Electricity," in which he collated and summarized a variety of data on this subject. His conclusion broadly was that the total cost of plant was on the average $400 per k. w., and that the cost of operation per unit output per year was under 50 cents. "That is, on the average, it requires 50 cents worth of plant to generate and distribute one k. w. hour per year." Discussion arose as to the correctness of the statement in the paper that at the Budapest station, the gross watt hours per pound of coal were 575 and 571. This was attributed to the very high price and grade of the coal.

Mr. Creden—The Chicago Edison Co. generates a k. w. on about 4½ pounds of coal, equivalent to about 28 pounds, which gives an evaporation of about six pounds on an average to a day's run. Coal as used in Budapest would safely give about ten pounds on an average, which readily accounts for the large number of watts generated. The Chicago Edison Co. generates about 250 watts per pound of coal. The coal we use will give an evaporation of six pounds, perhaps a trifle less, on a run of 24 hours. The coal at Budapest is of a better quality and will give an evaporation of ten pounds, which will account for the high figure specified.

President Insull—I have here a chart which shows the average cost of various operations in connection with Chicago Edison operating expenses, except the interest portion of the operating expenses. The columns here show the interest charges with different character of load factors. I present this to you now as it is a matter bearing not only on my own remarks, made a short time since on the question of cost and selling price, but also upon the paper just read. These figures are taken from our actual balance sheet of the year. The largest amount of expenses is general expenses. The reason for that is that one-third of the expense is in getting new business, one-third administrative expenses, and the balance insurance, taxes and similar items. The biggest item of expense apart from general expense is, as Mr. Rice indicated, lamp renewals, when he referred to the question of regulation being more important than the question of economy.

The important point that the chart brings out is the interest cost. You might have all of your operating expenses presented to you outside of interest and then you could lose money—it would be possible to do such a thing if your selling price is not on the right basis. Here is a case of a 3.7 load factor. It is an office building, not an extreme case. I could show you cases where the load factor would be much poorer than that, but in that case the interest charge is 80 per cent. of the total operating charge. Here is a case of an ordinary fancy store—these cases are taken from the actual bills—and you see there that the interest charge is a little less. The importance of the interest charge in this case will be brought home to you when I tell you that the difference between six and five per cent. in the price you pay for your money and whether you sell your bonds at 90 per cent. or sell them at par, makes a difference of 16 to 20 per cent. in the cost of operating expenses. That statement alone will show you that the public (generally) is more interested than we are in the question of protecting us in the enjoyment of our right to do business.

Now we come to the all-night restaurant where the load factor is 48 per cent., the interest charge is only 26 per cent. of the total expenses. These are the two extreme cases I mentioned to you in my opening remarks. In one case you could sell current to a man at about a quarter what you could sell it to another man, and make more money out of one than out of the other. You will find that the same relation goes all the way through with the different classes of business. Power business is not quite as good as all-night lighting business. The load factor is about 35 per cent. and the interest expense 32 per cent. With a dry goods store the interest is about 40 per cent. With a small lunch counter the interest is 45 per cent., and with a saloon the interest is 52 per cent.

It is generally supposed that the best business is the power business. I remember in the early days, when the rates were established to foster the power business of the Edison Electric Illuminating Co., of New York, the claim was made that you could afford to sell power at one-half the price if your current was going to be used for power when it was not going to be used for light. We have found that the power curve and the light curve cross each other for 60 days during the winter, and the claim which was made for the power business proved a fallacy.

In the lighting business of people with large stations you can get a class of business which will yield you a bigger return on your investment from lighting customers than from power customers at a low rate, because the interest cost, if you have a 50 per cent. load factor, is only 25 per cent. of the total cost; whereas with power customers the interest is about 35 per cent. This chart properly studied should enable a man running the Chicago Edison Co. to make a price list that would fit all kinds of customers. If we can do that in our business, surely you can do it in your business. You will find, too, that the adoption of a system of rates that will take care of these different conditions, will affect various items very materially. It will not affect lamp renewals, of course. It will certainly affect station repairs, general supervision, station labor, fuel and also general expenses. In other words, it will affect by far the greater proportion of your expenses outside of interest charges, besides very materially affecting your interest charges, by putting your revenue on a basis so that it is in proportion to the interest you have to pay to take care of the customer whom you are supplying with current. You are putting your business on a basis so that you get a return on the investment which you have to provide for each separate customer. You may take an office building as a good business policy, but do not fool yourselves when you put on 5,000 lights in an office building, that you are necessarily going to make any money on them. We do the largest office building business in the country, and I am perfectly willing to say to you that I do not believe we make any money on it.

Mr. Ferguson—We take in Chicago every and any customer on that basis, and we have a uniform schedule of prices for everybody, based on one cent per lamp per hour; that is the base rate. We charge the full rate of one cent per lamp per

[1]See page 670 this issue.

hour for one hour per day as the maximum demand, and for all watt hours beyond that hour, we charge a half rate, 40 per cent. or 60 per cent., or anything you please. In regard to the question of what customers you can afford to take, that would involve a great deal of calculation. The simplest way is to charge a minimum bill to each customer, which will cover the smallest customer. If you charge a minimum bill for services furnished, that will cover interest and depreciation charges on the cost of the investment used.

Mr. Wagner—I understand that the Chicago Edison Co. is going to use the Wright demand system of charging, which is a very thorough way of providing for all these different classes of services. I should like to know if there is any one else here who accomplishes nearly the same thing by any other method?

Mr. Dow—I have been into this thing up to my neck in Detroit. I suppose that remark will interest a good many members here from small towns, say of 25,000 inhabitants. We have more than 25,000 people, but we have not money enough to buy Wright demand meters for all our customers just yet. We are going to do so some day. However, we use demand meters on a number of customers. We use them when there is doubt of arriving at the demand by any other means. We do not believe it necessary to leave them on continuously, but we put them on long enough to make certain that we have a fair average demand for the current twelve months, and in such cases we make the demand established by meter, and base a contract on it with the customer for the current twelve months. We say to them that they shall pay for that amount for twelve months, at the maximum rate, and everything beyond that at a minimum rate, and at the end of twelve months we will again meter in the same way, and reserve the right to put the meter on at any time to satisfy ourselves as to what the actual demand is. In some places we leave the meters on continuously. We would do so all the way through, but for the one point of not having money enough to put them on everybody.

Mr. Ayer—If there is any place in the world where a demand meter is a good thing it is in a residence. In the absence of the meter system in residences we have instituted a method of assessment according to the number of rooms in a house and the number of persons likely to use the light. We inspect each house and make a list of the rooms and the number of lights in each room; and we make a charge accordingly.

Mr. Ferguson—Mr. Dow made the statement that he could not afford to buy demand meters. He can do it after a while, but cannot afford to do it now. After listening to what he said I think he is much mistaken. I think he is spending too much of his valuable time in attempting to understand the personal characteristics of his customers. I am sure that if he does that properly, if he ascertains the characteristics of his customers so well that he can approach the work done by the Wright demand meter, he must employ a large force of assistants, and when we consider that the cost of demand meters is small in proportion to the total investment, and when we consider the immense amount of business that can be obtained by using the demand meters, I think he can well afford to buy them. With an instrument like the Wright demand meter you are put in a position where the instrument does for you what you will otherwise have to do by skilled labor at a very high cost. I say this from experience. For three years I have personally negotiated contracts for the Chicago Edison Co. on a basis similar to that described by Mr. Dow. I have had customers come into the office and talked with them to ascertain the conditions under which they burned their light, and made prices, with 15 and 25 and up to 65 and 75 per cent. discount, depending on the conditions under which they used the light. Since we have put in the Wright demand system the work is lessened, I am able to give my attention to other things and let the meter do the work for me. There are other ways, of course, at getting at the information and we have used them. We have used for instance the Bristol recording ammeter, which is useful for ascertaining the maximum load in any customer's premises. It is slow and can only be used in large installations, like hotels and theatres, where you desire to make a uniform discount for the entire year, which is practically the same as selling current on the Wright demand system. It is the load factor system; the only system based on load factor. If you know by the Bristol recording instrument that the load factor is 50 per cent., you can make the rate for the entire year at a uniform discount, which is the same as putting in the Wright demand instrument. It is tedious and much more expensive than buying the instruments and asking them to do the work for you.

Mr. Weeks—There have been few discussions before this association of greater importance to central station interests than that to which we have just listened. In the cost of our product the relative value of the interest factor has been forcibly and clearly shown, and the necessity for revision of rates or discounts has been ably demonstrated. In my judgment the method employed by Mr. Insull, or a slight modification of it, will soon come into general use. In one respect, however, the practice as stated strikes me of questionable equity, if not expediency, and I would like to ask what has been the effect upon your revenue of the lower rates for summer service.

Mr. Insull—We do not know yet. We only put it in operation during the last few weeks.

Mr. Weeks—It seems to me that it is somewhat inequitable to make a lower rate for transient summer service, such as that of the customer who operates a fan but a few weeks or months at most in the year, while his rate on account of the interest factor should be higher rather than lower than that for most other classes of service.

Mr. Insull—We have a large by-product that we want to sell, which usually lies idle in the summer, and we endeavor to dispose of it to these casual users.

Mr. Weeks—What has been the effect of the Wright system, which is admirable and will undoubtedly be the system of the future, upon municipal lighting?

Mr. Ferguson—The municipal light runs about twelve hours. It depends whether it is a moonlight schedule or an all-night service. It would not get as low as you are selling it now. You can readily see that if you make the rate 20 cents the first hour, and ten cents for everything after that, the maximum discount will not reach 50 per cent. It is something higher than that now. It is the same as if you figure 10 cents per kilowatt hour. You will have to make the second rate low enough, so as to figure out the same kilowatt hour as you are now charging for the arc light service. That must be arranged for in each individual city.

On motion the meeting adjourned until 3 o'clock.

TUESDAY AFTERNOON SESSION.

President Insull called the meeting to order at 3.10 p. m., and announced the first paper to be that of Mr. Alexander Dow, of Detroit, Mich., on "Public Lighting, with Relation to Public Ownership or Control."

Mr. Dow's paper was followed by papers on the same subject by Mr. Samuel Scovil, of Cleveland, Ohio; Mr. H. M. Atkinson, of Atlanta, Ga., and Mr. C. W. Davis, of Williamsport, Penn.

At the conclusion of the reading of the above papers the meeting adjourned to executive session.

WEDNESDAY MORNING SESSION.

President Insull called the meeting to order at 10.30 a. m. Papers were read by Mr. H. A. Wagner, of St. Louis, on "General Distribution From Central Stations by Alternating Currents," and by Mr. Louis A. Ferguson, of Chicago, on "General Distribution From Central Stations by Direct Currents." These papers, which are printed in this issue of The Electrical Engineer, were the subject of an animated discussion, which waged all day long and covered the whole field implied by the titles. The discussion was participated in by Prof. Fujioka, Messrs. Wagner, Ferguson, Thayer, Van Trump, Dow, Wilmerding, Prof. Goldsborough, Scovel, Pillsbury, Insull, Ayer, Fakes, Stetson, Davis, De Camp, Hubeley, Chandler, Smith, Carnes. An abstract of the discussion will be given in our pages next week.

WEDNESDAY EVENING SESSION.

Mr. Joseph Wetzler delivered a lecture on "Electricity Direct From Coal" before the Association, with the aid of a stereopticon and a large number of lantern slides. The lecture was well attended.

THURSDAY MORNING SESSION.

President Insull called the meeting to order at 10:40 a. m., when Mr. W. McLea Walbank, of Montreal, read a paper on "Cost of Producing Electric Power by Water Power From Lachine Rapids, Canada."

This paper gave figures with regard to a now familiar in-

stallation and gave a total cost per kilowatt on a 24-four hour basis per day, per year, of $22.97 per k. w.

The paper was discussed by Messrs. Wagner, Ferguson, Insull, Davis, Anderson, Matlack and others, the chief aim being to get at what Mr. Walbank had included in his costs. Mr. Walbank said that the price to a customer for 100 h. p. ten hours per day per working year would be from $32 to $36 per h. p. Mr. Anderson, of Springfield, Mass., stated that their plant gave them an e. h. p. for $21.23, delivered, with no allowance for depreciation, repairs or interest.

Prof. W. E. Goldsborough then read a paper on "Transformer Economy," dealing with general features of the subject. It was discussed by Messrs. Layman, Thayer, Wurts, Wagner, Davis, Matlack, Walbank and Huntley.

The president named Messrs. A. M. Robertson, James Dee and James I. Ayer as a nominating committee to select officers and members of the executive committee for the ensuing year.

THURSDAY AFTERNOON SESSION.

President Insull called the meeting to order at 2:55 p. m. The first business was the report of the committee on "Standard Candle Power of Incandescent Lamps," Dr. Louis Bell, chairman. Mr. Ayer presented the report of the committee as follows:

REPORT OF COMMITTEE ON STANDARD CANDLE POWER OF INCANDESCENT LAMPS.

Your committee has been able to have tested in the most careful manner, through the courtesy of Prof. W. L. Puffer, of Boston, sixteen incandescent lamps from eleven different makers. The lamps were obtained directly from the makers or their authorized agents and were known to be for test.

These lamps were all sold for 16 c. p., 110 volts, no watts specified, and may be fairly assumed to represent the product which would be shipped to consumers who did not desire the lamps for test, although one batch of lamps came with the bases marked to show the point to be turned toward the photometer screen.

On test, these lamps, 33 in all, averaged 14.1 mean normal c. p. and about 11.7 mean ph. c. p. Only one batch of three averaged over 16 normal c. p. One batch fell below 11 normal c. p. and two below 12 normal c. p. Five makers fell below 14.5 normal c. p. The highest average of any batch was 16.99, the lowest 10.82. The average consumption of energy was almost exactly 4 watts, the lowest 3.78 watts per candle and two batches ran over 5 watts. It should be noted that the voltage was determined by a Weston volt meter freshly compared with Clark cells and each lamp was marked at its marked voltage (110).

A separate series of tests showed that these lamps on the average gave their mean sph. c. p., when measured under rotation with their axes tilted 44 degs. and 24 min. from the vertical toward the photometer, thus confirming closely your committee's estimate of 45 degs. as a proper angle.

A series of tests on proper speed of rotation showed that the best results were obtained with a speed of 200 to 250 revolutions per minute, and that the lamps would readily stand this speed.

Many of the lamps showed bad spherical distribution, which seems to be quite needless since it is merely a matter of proper proportioning the form of the filament.

Of an equal number of batches of 32 c. p. lamps only one batch averaged 32 normal c. p., the majority falling to from 26 to 28 c. p. The 32 c. p. lamps averaged slightly greater efficiency, but were otherwise much like the 16 c. p. size.

From this investigation the fact stands out that the incandescent lamp sold for 16 c. p. is, on the whole, a lamp which is often giving considerably less than its rated c. p. even when new. Some of these lamps would probably show a temporary increase of c. p. after, say 50 hours' burning, but the committee has not extended the research in this direction as yet, and adheres to the opinion that the initial candle power is the only practicable commercial test, and any increase consequently is simply to be regarded as a device for keeping the lamp a little longer from its inevitable decay.

From these and other data kindly furnished by manufacturers and obtained from various other reliable sources, your committee is convinced that the need of a uniform rating is even greater than it concluded in the preliminary report of last year, and that a rating test in order to be effective must involve measurement of candle power of lamps in more than one direction. Neither mean horizontal nor mean spherical candle power, nor candle power in any one direction, will define a lamp well enough to insure adherents to the rating. Your committee therefore recommends that incandescent lamps be required to conform both to a standard mean normal candle power and to a mean candle power when revolved with the axis tipped 45 degs., this representing the spherical distribution. It recommends that the limits for the mean normal c. p. be 15 and 17.5 c. p. Unless the minimum be as high as 15 there will certainly be found a tendency to produce lamps near the lower limit. The 45 degs. c. p. should be at least 85 per cent. of this minimum. This is not an excessive requirement and will tend to prevent working near the lower limit of horizontal c. p. unless with a lamp very good in other respects.

Your committee has blocked out a standard form of photometer, a type of which it proposes to build, test and put at the disposal of the Association with directions for proper use.

It suggests that testing be by sample, a lot of ten lamps being taken from each barrel. Of these no lamp when run at its marked voltage shall show less than 15 or more than 17.5 c. p. mean horizontal, when rotated at 200 to 250 revolutions per minute; and no lamp shall give when thus rotated at 45 degs. inclination less than 85 per cent. of the above minimum.

The committee will make arrangements for standard lamps as indicated in the preliminary reports to go with the standard photometer.

Mr. Burleigh moved that the report of the committee be adopted, that this committee be discharged and another committee be appointed to continue the work. Motion carried.

PREST. A. M. YOUNG.

(Mr. Young is president of the New England Engineering Co., and is actively interested in a number of electric lighting and railway enterprises. He began his electrical career as a telegrapher.)

The president appointed as a committee: Chairman, James I. Ayer, of Boston; Louis A. Ferguson, of Chicago, and Calvin W. Rice, of Brooklyn.

The Committee on Amendments to Freight Classification requested further time to report, and the report was postponed until the next meeting.

The Committee on Legislation Concerning Theft of Current made an oral report, in which they stated that the committee had collected laws passed in twenty-seven different States bearing on this subject and they recommended that the same be published for the benefit of the members of the Association. The recommendation of the committee was adopted, and a new committee was formed, as follows: Chairman, E. A. Armstrong, of Camden, N. J.; James I. Ayer, of Boston, and A. W. Field, of Columbus, O.

The meeting then adjourned to executive session.

The report of the secretary and treasurer was presented, showing the affairs of the Association to be in a flourishing condition.

Mr. Armstrong moved the following resolution: "Resolved: That the annual meeting shall be held in May or June in each year, alternately in the cities of New York and Chicago, unless otherwise directed by the executive, and on such date as the committee shall determine." Adopted.

Mr. Atkinson moved, and a very hearty vote of thanks was passed, to President Insull for his untiring efforts for the success of the Chicago convention.

Mr. Ayer moved that the thanks of the meeting be extended to the Chicago Edison Company, the Metropolitan West Side elevated road, the South Side elevated road, the Northern Steamship Company, the Chicago Telephone Company, the American Telephone and Telegraph Company and all others who had extended courtesies to the convention for their kindness in so doing.

Mr. Field moved a vote of thanks to the reception committee for their very considerate attention to the ladies accompanying the delegates to the convention.

The following officers were elected for the ensuing year: President, A. M. Young, Waterbury, Conn.; first vice-president, E. H. Rollins, Denver, Colo.; second vice-president, F. A. Gilbert, Boston, Mass.; members of the executive committee, Samuel Insull, Chicago, Ill.; Samuel Scovil, Cleveland, O.; H. M. Atkinson, Atlanta, Ga.; F. A. Copeland, La Crosse, Wis.

The convention then adjourned sine die.

Convention Entertainments.

On the evening before the opening of the convention a reception of the visiting members was held in the Auditorium parlors. President Insull, aided by the members of the reception committee, received the guests, many of whom were attended by ladies. The occasion served to assemble many who had not met in years, as the choice of Chicago brought out many members who had been prevented from attending the recent meetings in the East. An excellent band furnished music and after refreshments had been served, dancing was the order of the day.

For those for whom dancing has no charms, the committee had provided a retreat in the Auditorium club rooms, nearby. There the gentlemen discussed central station matters, as well as some other things, and it was in the small hours of the morning before the discussions ended.

The ladies, as usual, were not neglected, and their comfort and entertainment were exceedingly well looked after, due to the kind attentions of the Chicago ladies. On Tuesday a ladies' coaching party drove through the South Side parks, stopping at the Washington Park Club, where a sumptuous luncheon was served. Unfortunately, a heavy thunder storm marred somewhat the pleasure of the occasion, but the weather could not dampen the high spirits of the party. On Thursday afternoon the ladies were taken for a drive through Lincoln Park and along the north shore.

Inspection of the Sprague System—Chicago South Side.

On the invitation of the Sprague Electric Company a number of the convention delegates on Tuesday night inspected the workings of the South Side elevated railroad, a special train having been placed at their disposal by President Carter, of the South Side company, under the immediate charge of Superintendent Morrison. The train was made up of brand new cars and all the appointments were of the highest order of excellence and beauty. The train was put through a number of severe tests, showing in a marked degree the great value of the Sprague multiple unit plan of electric train operation. It was run at variable speeds and stopped and started at various depots. The acceleration tests at starting were the subject of particular comment, as they showed how remarkably fast a train can be brought up to speed from dead rest on the Sprague system.

The trip lasted one and one-quarter hours and gave great satisfaction to all who were present. Besides the members of the National Electric Light Association there were also present members of the Illinois Street Railway Association; Mr. Albion T. Lang, of Toledo, O., and Mr. David Belden, of Aurora. The Sprague company was represented by Messrs. E. H. Johnson, Charles A. Benton and W. H. Sheppard, the last of whom has had immediate charge of the work of equipment for the Sprague company.

JAMES C. WORMLEY & CO., Chicago, exhibited a full line of incandescent lamps of 2 to 250-volts, ⅕ to 50 c. p., as well as a line of filaments, from raw state to flashed carbons, ready for use. Their exhibit in parlor 132 contained also a handsome display board, showing about 60 lamps burning, no two alike.

Convention Notes.

COL. S. G. BOOKER was in attendance at the convention and looked after the interests of the Phoenix Carbon Company, of St. Louis, with his usual good humor.

THE OKONITE COMPANY, of New York, was represented by Captain W. L. Candee and Mr. George T. Manson, who looked after the interest of the delegates with their usual warm hospitality. Their Louis XV. plaques were the handsomest advertisements ever distributed at a convention.

WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., occupied suite 622. Their rooms were tastefully decorated with framed half-tones of the many kinds of generators, etc., installed in different plants throughout the country. In attendance was Mr. E. H. Abadie, manager of sales department; Mr. H. A. Wagner was also in attendance.

SAWYER-MAN ELECTRIC COMPANY, Pittsburg, occupied parlor 106. This company had a very neat showcase, in which were displayed a full line of plain and colored incandescent lamps of various voltages and candle power. The exhibit was in charge of Mr. F. S. Smith, the manager of the company, Mr. C. A. Ross and Mr. F. D. Rusling.

JOHN CHILD, 1563 Monadnock building, Chicago, representing A. O. Schoonmaker, of New York, brought his mica to the front. He resorted to the clever idea of suspending a large piece of mica over the stairway leading to the main corridor of the Auditorium. The card was a drawing one and was seen by all visitors at the convention.

PORTABLE ELECTRIC LIGHT COMPANY, of 1242 Marquette building, Chicago, showed a line of portable electric lamps for bicycles, carriages, house and factory use, as well as electric lighting apparatus for medical and surgical use. The instruments are something entirely novel, consisting of otoscope and laryngeal sets for examinging throat, ears and other organs. They exhibited also a gold bicycle lamp fastened to a silver-plated bicycle.

KIELY & MULLER, 7-17 West Thirteenth street, New York, exhibited their Climax damper regulator on the main floor of the Auditorium. A handsome working model, as well as a sectional model of this device, was shown, and was viewed with interest by a large number of visitors. The exhibit was in charge of Mr. Timothy Kiely, assisted by Mr. C. F. Mitchell and their Western manager, Mr. George E. Boylston.

L. A. CHASE & CO., 161-163 Forthill square, Boston, exhibited their improved Chase knockout junction boxes, also their new direct current circuit breaker. Great interest was shown in L. A. Chase & Co.'s specialties, a great number of descriptive circulars being carried away by visitors to the convention who were impressed with the decided improvement in their individual specialties. Mr. Sears Condit, of the firm, had charge of the exhibit.

WESTERN ELECTRIC COMPANY, Chicago, occupied room 4 of the main floor. They exhibited their Standard Western Electric fan motor, also a showcase containing a full line of Sunbeam lamps of various voltages. In practical operation was shown also their improved arc lamp, which, with the others, attracted quite a number of visitors. In attendance at their exhibit we noted Mr. C. D. Crandall, manager of the company; Mr. A. L. Tucker, manager of the supply department; Col. G. L. Beetle, L. K. Comstock, J. W. Ebert, Thos. G. Grier, Chas. Wilkinson and J. L. Jackson.

D. & W. FUSE COMPANY, Providence, R. I., had an exhibit of their non-arcing fuse in the main corridor of the Auditorium. The exhibit comprised a full line of fuses for both low tension and high tension service, together with the fittings for the same, manufactured by this company. These fuses have now been on the market for over a year and have demonstrated the claim made by the D. & W. Fuse Company as to their accuracy and reliability under all conditions. Their telephone protectors have met with great favor and have been very extensively installed throughout the country.

WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, Pittsburg, Pa., occupied parlors 104 and 106, on the main floor. The rooms were tastefully decorated with American flags and on the walls were framed half-tones of the company's installations of all kinds of electrical apparatus, especially large generators. Pamphlets dwelling upon their entire

line of manufacture were presented to all visitors to their parlors. In attendance we noted Mr. F. H. Taylor, sales manager; Mr. Arthur Warren, Mr. Alexander J. Wurts, Mr. A. S. Morris, Mr. W. S. Rugg, Mr. Henry Floy, Mr. C. W. Register and Mr. Maurice Coster.

MR. C. F. MUNDEL represented the Davis Electrical Works, of Springfield, Mass.

PERU ELECTRIC MANUFACTURING COMPANY, of Peru, Ind., was represented by Mr. R. C. Bouslog, who had some interesting samples of their well-known china goods to distribute.

THE COLUMBIA INCANDESCENT LAMP COMPANY, of St. Louis, was represented by Mr. A. C. Garrison, who had no exhibit, but had a lot of valuable information to give away on the subject of incandescent lighting.

THE INDIANA RUBBER AND INSULATED WIRE CO., of Marion, Ind., were represented at the convention by their popular secretary, Mr. R. E. Lucas, who reported that business was never better than at present.

MR. C. G. PERKINS represented the Perkins Electric Switch Company, of Hartford, Conn.; Mr. J. H. Reid, the Pittsburg Glass Company; Mr. A. Smith, the firm of Keelyn & Smith, Milwaukee, and Mr. E. R. Grier, the Bryant Electric Switch Company, of Bridgeport, Conn.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, occupied the large suite 126 in the Auditorium. The walls of the rooms of this company were hung with quite a number of pictures showing the installations in many stations undertaken by the Electric Storage Battery Company. A large attendance of visitors to their rooms were presented with catalogues and pamphlets. They were represented by Messrs. H. Lloyd, J. Appleton, J. R. Williams, F. H. Clark and L. B. Daggett.

THE MANHATTAN GENERAL CONSTRUCTION COMPANY, of New York, was represented by Mr. S. Marsh Young, who had on exhibition for the first time their new types of "Manhattan" lamps for direct current and alternating circuits. One of the new features of the direct current lamp is that it can be used singly in 220-volt circuits, by a simple change of the magnet. These new Manhattan lamps have been simplified, and Mr. Young had on exhibition the detail parts of the lamp which showed conclusively to those interested the great improvements they have recently made in lamp construction. A full and illustrated description of these lamps appears in this issue.

STERLING ARC LAMP COMPANY, 214-222 West Twenty-sixth street, New York, occupied parlor 1162 of the Auditorium Annex. Their exhibit comprised a rack of seven Sterling enclosed arc lamps, shown in neat and artistic designs. These lamps are built to burn on all circuits. A specialty shown were their series lamps 6½ and 9½ amperes, 65 volts, which created unusual interest among the many central station men visiting the company's room. A neat advertising souvenir in the shape of a lead pencil and cigar cutter combined was presented to the visitors. Mr. R. J. Randolph represented the company at the convention, the rooms showing his artistic taste, being decorated with American Beauties and La France roses. Needless to say, he had many lady callers.

SPRAGUE ELECTRIC COMPANY, New York, occupied a large suite of rooms and had a full line of literature on their new Lundell slow speed motors, especially adopted for all classes of direct connected work. Among the specially attractive and effective literature of this company we mention their '98 "Lundell Fan Motor Catalogue," their pamphlet on "Electric Motors in the Art of Printing;" also the first issue of their new "Architects' and Engineers' Electrical Bulletin." The last publication will from now on be issued monthly, being of especial interest to the parties for whom intended. The company showed a most attractive exhibit of Lundell fans, located prominently all over the Auditorium Hotel, supplying cool breezes throughout the building. The company was represented by Mr. Ed. H. Johnson, the first vice-president and general manager of the company; W. H. Sheppard, Mr. C. A. Benton, general sales manager; Ed. B. Kittle, Chicago agent, and Mr. M. B. Kitt. This being Mr. Johnson's first visit to the convention after several years of absence, his large circle of acquaintances were very glad to greet him.

STANDARD UNDERGROUND CABLE COMPANY exploited their cables and wires in room 134.

THE H. B. CAMP COMPANY, of Aultman, O., had its ever popular representative, Mr. Daniels, on the ground, who talked up underground conduit in his usual able manner.

MR. CYRUS O. BAKER, JR., master of transportation, was elected an honorary member of the National Electric Light Association at the Chicago convention. The honor is well deserved and has been more than earned by long and devoted service to the Association.

EUGENE MUNSELL & CO. and the Mica Insulator Company, of New York and Chicago, were represented by Mr. Chas. E. Coleman, manager of the two concerns in the West. The companies' blotters were distributed freely at the writing rooms and various headquarters of the different companies represented at the Auditorium during the convention.

J. HOLT GATES & CO. was represented at the convention by J. Holt Gates, Geo. B. Foster and C. H. Philbrook. This firm handles the apparatus of the Walker Company, of Cleveland, O.; of the Wagner Electric Manufacturing Company, of St. Louis, Mo., and the Card Electric Company, of Mansfield, O. They report the sale last month of 1,900 k. w. of generators, besides numerous switchboards, street railway equipments and other electrical details.

THE WALKER COMPANY, of Cleveland, was represented by J. Holt Gates, Geo. B. Foster, C. H. Philbrook and F. H. Talbot, of the Chicago office. Many of the delegates were interested in the new alternating system of the Walker company, as well as its new solenoid blow-out controller, also the "L" type of street railway motor of 150 h. p., 20 of which are being supplied the Metropolitan elevated railroad of Chicago. Many of the visitors called at the new station of the Chicago City railway, which is designed for 15 880 k. w. Walker rope-driven generators.

BISMARCK, the great German statesman, remarked to Mr. H. H. Brooks, upon a recent visit to the old country: "My dear sir, do not think of giving up smoking. When will you think?" This little remark has borne its fruit at the National Electric Light convention. Mr. Brooks wants his friends to think about him, and especially about Circular Loom, so to aid those who had acquired the habit of thinking, he presented to visitors a beautiful briarwood pipe, a box of "never-blow-out" matches and a bag of Durham smoking tobacco. On the lid of the box enclosing this most acceptable souvenir was the inscription: "Smoke Up With the American Circular Loom Co., Chelsea, Mass. Flexible Conduit Electroduct." While the fragrant smoke is wafted towards the azure vault of heaven, as the sturdy wireman trudges along with his load of 200 feet of circular loom on his shoulders, he will think, and Mr. Brooks and his company may be assured that the thoughts will be pleasant ones. And when in the fading hours of the day the station manager takes his well-earned rest, with his child upon his knee and his briar in his mouth, the sweet incense from the mellow weed will rise in praise of the worth of the American Circular Loom.

THE GENERAL ELECTRIC COMPANY was represented at the convention by the entire selling staff of its Chicago office and by several representatives from its other sales offices. It made no exhibit, but parties of delegates were made up for the purpose of visiting the different great stations in Chicago equipped with the latest types of General Electric apparatus. A large delegation accepted Mr. B. E. Sunny's invitation to visit the large store house and repair shop which the General Electric Company has established in Chicago, for the purpose of facilitating its relations with the customers in the great territory covered by the Chicago office. The General Electric Company made its headquarters at the Auditorium Hotel in room 140, which was tastefully decorated with palms and ferns. A supply of illustrated literature was also provided for those interested. The interests of the company were cared for by the following gentlemen: B. R. Sunny, F. N. Boyer, Theo. P. Bailey, J. Scribner, W. S. Arnold, W. J. Ferris, G. J. Cadwell, J. W. Buell, J. W. Johnson, E. C. Noe, O. E. Turner, A. J. Gifford, G. H. Atkin, H. T. Windsor, S. F. Dibble, W. H. Colman, J. J. O'Brien, P. A. Clisdell, Geo. D. Rosenthal, J. H. Livsey, W. F. Hays, W. J. Hanley, I. R. Prentiss, F. M. Kimball, H. H. Crowell, W. S. Andrews, J. Dalzell and A. D. Page.

THE ANCHOR ELECTRIC COMPANY, Boston, was represented by Mr. Norman Marshall.

THE LAKON COMPANY, Elkhart, Ind., manufacturers of transformers, etc., were represented by their president, Mr. John C. Boss.

HAYES & ARTHUR, of Cleveland, were strongly in evidence, Mr. Scott Hayes winning hosts of new friends for himself and his company.

OTIS BROS. & CO., New York, were represented by Mr. W. D. Baldwin, who had interesting information to give out on the subject of electric elevators.

CUTTER ELECTRIC MANUFACTURING COMPANY were represented by Mr. Henry B. Cutter, and showed up their I-T-E. samples and catalogue.

CHAS. A. SCHIEREN & CO. had their Western representative on the ground, Mr. A. W. Watriss, who looked after the interests of the delegates with great urbanity and incidentally talked up belting.

COL. SHAY, of the MUNSON BELTING COMPANY, distributed large numbers of war maps of Cuba, which were eagerly sought by the delegates, and proved acceptable souvenirs in these war times.

THE WASHINGTON CARBON COMPANY, of Pittsburg, was represented by Mr. J. S. Crider, who interested many of the delegates with valuable information on the subject of carbons for lighting and other purposes.

THE NATIONAL UNDERGROUND CONDUIT AND CABLE COMPANY, of New York, was strongly represented by Mr. J. P. McQuaide and Mr. Jackson, both of whom required no introductions to the delegates.

AMERICAN ELECTRICAL WORKS, Providence, R. I., was represented by its president, Mr. Frank N. Phillips, and its Chicago representative, Mr. F. E. Donohoe. Both gentlemen were constantly greeting their numerous friends.

THE STANDARD PAINT COMPANY, of New York and Chicago, were well represented by their Western manager, Mr. J. C. Shainwald, who had a neat little souvenir to give away in the shape of a manicure nail file. There are still a few of them left.

THE ELECTRIC APPLIANCE COMPANY, of Chicago, was naturally in evidence at the Auditorium, though they had no exhibit there, Messrs. Low and Stacy being contented to circulate around among their numerous friends and entertain them with their usual well-known generous hospitality.

McKINLOCK & CAMP, of Chicago, were well represented by both members of the firm, who made a lasting impression on their many friends by their genial hospitality and pervading good humor. Both gentlemen were at the front in all the little entertainments usual at convention time.

THE VALENTINE CLARK COMPANY, of Chicago, was well represented by both members of the firm, who, by their universal politeness and geniality, made numerous friends among the central station men and interested them in their enormous facilities for shipping poles for all electrical purposes.

THE DEARBORN DRUG AND CHEMICAL COMPANY, of Chicago, were represented by their vice-president and general manager, Mr. Robert F. Carr, who interested many of the central station men in their elaborate laboratories for testing the water used in boilers, and in their various compounds for preserving them from incrustation.

AMERICAN CIRCULAR LOOM COMPANY occupied spacious room 1530 in the annex of the Auditorium. The firm was represented by genial Mr. Brooks, who received a constant stream of friends and visitors to the convention. Mr. Brooks also presented all callers with one of the best advertising souvenirs of the firm, consisting of a complete smokers' outfit—briar wood pipe, with pouch of best Durham tobacco and box of matches.

THE CENTRAL ELECTRIC COMPANY, of Chicago, decided to have no exhibit at the Auditorium, but had some large cards printed, giving a cordial invitation to visit their handsome new store, 264 to 270 Fifth avenue. Messrs. George A. McKinlock, Chas. E. Brown, C. W. Cobb, W. P. Upham and C. G. Burton were all in attendance, and many of the delegates took the opportunity to visit their store and to enjoy the cordial welcome always extended by this popular company.

List of Visitors at the Chicago Convention.

ATLANTA, GA.—H. M. Atkinson, J. H. Ely.
BALTIMORE, MD.—D. P. Robinson.
BAY CITY, MICH.—James G. Lowell, J. J. Thorne.
BELLEFONTAINE, O.—John M. Gregory.
BELLE PLAINE, IA.—George L. Thayer.
BELLEVILLE, ILL.—J. Frank Andres.
BIRMINGHAM, ALA.—J. M. Bradley.
BOISE, IDAHO.—J. W. Cunningham.
BOSTON MASS.—James I. Ayer, F. E. Barker, H. T. Edgar, Fred. M. Kimball, N. Marshall, George B. Neal, F. E. Smith, T. Ellwood Smith, D. F. Urquhart.
BROOKLYN, N. Y.—James Ferguson, C. W. Rice.
CAMDEN, N. J.—E. A. Armstrong, J. J. Burleigh, Walter E. Harrington, Mrs. Walter E. Harrington.
CHAMPAIGN, ILL.—B. F. Harris, Jr.
CHARLESTON, N. C.—F. A. Brooks.
CHARLOTTE, N. C.—W. T. Engel.
CHICAGO, ILL.—John Jay Abbott, W. L. Abbott, R. D. Allen, W. L. Arnold, G. H. Atkins, J. M. Atkinson, H. D. Babbitt, F. B. Badt, Edw. L. Barr, A. Bement, F. N. Boyer, W. G. Carlton, R. F. Carr, H. Cheney, Frank H. Clark, L. K. Comstock, George W. Conover, J. H. Cooke, Maurice Coster, J. R. Cravath, T. H. Creden, Harry H. Cutler, George Cutter, Fred. De Land, S. F. Dibble, J. W. Ebert, Charles M. Eddy, Louis A. Ferguson, W. J. Ferris, W. E. Finney, George B. Foster, Robert W. Francis, Jacob Frank, S. S. Frank, J. H. Goehst, Edward R. Grier, Thomas G. Grier, Edward M. Hagan, F. D. Hart, Jr., William S. Hine, H. R. Hixson, W. F. Hold, J. M. Hollister, Samuel Insull, George H. Jones, C. E. Kammeyer, W. F. Keily, M. B. Kitt, E. B. Kittle, J. M. Knox, G. A. Edward Kohler, C. L. Leibrook, Theodore Graham Lewis, T. Julian McGill, Charles Messer, H. B. Morgan, A. M. Morse, S. F. B. Morse, Charles B. Obermeyer, J. B. O'Hara, W. E. Pimlott, Charles A. Pratt, W. R. Pritchard, William D. Ray, C. A. Ross, J. Scribner, John J. Schayer, R. F. Schuchardt, J. C. Shainwald, J. H. Shay, William M. Smith, John Svenson, George Tailleur, H. L. J. Towner, W. P. Upham, A. W. Watriss, C. J. Wells, George S. Whyte, J. R. Wiley, C. D. Wilkinson, C. H. Wilmerding, H. H. Windsor, John Young, J. F. Conner, Thos. S. Gordon, M. E. Patterson, E. E. R. Tratman.
CINCINNATI, O.—W. J. Hanley, W. P. Hays, W. M. Hubbard.
CLEVELAND, O.—S. O. D. Johns, L. H. Rogers.
COLORADO SPRINGS, COLO.—E. E. Wade.
COLUMBUS, O.—A. W. Field.
DAYTON, O.—James C. Reber.
DECATUR, ILL.—J. H. Culver.
DENVER, COLO.—M. L. Stern.
DERBY, CONN.—Robert E. Wyant.
DES MOINES, IA.—R. H. Fraser.
DETROIT, MICH.—George W. Cate, Alexander Dow, J. H. Livsey, Joseph D. Lockwood.
DUBUQUE, IA.—William S. Mold, H. G. Torbert.
ELKHART, IND.—A. M. Barron.
EVANSTON, ILL.—E. W. Clark, J. B. Morrill.
FARMINGTON, ILL.—E. M. Rose.
FITCHBURG, MASS.—H. F. Coggshall.
FORT SCOTT, KAN.—C. F. Drake.
FOSTORIA, O.—J. B. Crouse.
FREMONT, O.—A. J. Blum.
HARTFORD, CONN.—C. G. Perkins.
HOUGHTON, MICH.—James R. Dee.
HOOPSTOWN, ILL.—C. H. Trego.
INDIANAPOLIS, IND.—C. C. Perry, G. O. Rockwood, C. H. Varney.
JACKSONVILLE, ILL.—J. P. Doan.
JANESVILLE, WIS.—E. P. Norcross.
JOHNSTOWN, PA.—J. W. Reeves.
JONESVILLE, MICH.—L. H. Gilbert.
KANSAS CITY, MO.—Edwin R. Weeks.
LA CROSSE, WIS.—F. A. Copeland, C. H. Greenwood.
LAKON, IND.—Gerald Mahony.
LOGANSPORT, IND.—Elmer Woodling.
LONDON, ONT.—Charles B. Hunt.
LOUISVILLE, KY.—G. Wilbur Hubeley.
MEMPHIS, TENN.—S. T. Carnes.
MILLEDGEVILLE, ILL.—P. Dull.
MILTON, PA.—W. W. S. Butler.
MILWAUKEE, WIS.—Thomas H. Ferris, Thomas R. Mercein.
MINNEAPOLIS, MINN.—Percy A. Clisdell, B. B. Downs, Henry Floy, A. M. Robertson.
MONTEREY, MEX.—E. Dystend.
MONTREAL, CAN.—R. S. Kelsch, W. McLea Walbank.
MUNCIE, ILL.—Hal. C. Kimbrough.
MUNCIE, IND.—O. Mitchell.
NASHVILLE, TENN.—Frederick S. Pratt.
NEWARK, N. J.—A. D. Page.
NEW BEDFORD, MASS.—Charles R. Price, George R. Stetson.
NEW ORLEANS, La.—W. M. Brooke, R. S. Stearnes.
NEWTON, IA.—A. C. Yates.
NEW YORK, N Y.—C. O. Baker, Jr., C. A. Benton, Willard L. Candee, Charles T. Child, T. E. Crossman, C. J. Field, Dr. William Habirshaw, George T. Jackson, Edw. H. Johnson, E. A. Leslie, George T. Manson, Converse D. Marsh, J. McGhie, James P. McQuaide, George F. Porter, Charles W. Price, Charles D. Shain, A. C. Shaw, Luther Stieringer, H. M. Swetland, Jefferson Wetzler, Joseph Wetzler, Mrs. Joseph Wetzler, Elmer E. Wood, J. E. Woodbridge, S. Marsh Young, John H. Dale.
NILES, MICH.—W. H. Tompkins.
NOBLESVILLE, IND.—A. F. Webb.
NORFOLK, VA.—Peter Wright.
NORTH EAST, PA.—A. L. Daniels.
OKLAHOMA CITY, O. T.—J. G. Fakes.
OTTAWA, ILL.—Douglas Hapeman.
PEKIN, ILL.—Thomas Cooper.
PEORIA, ILL.—G. G. Luthy, G. A. Scheeffer.
PHILADELPHIA, PA.—J. Appleton, Henry B. Cutter, Mrs. H. B. Cutter, A. J. De Camp, A. V. Dee, Herbert Lloyd, J. R. Prentiss, E. Ward Wilkins, John R. Williams, John Mustard.
PINEVILLE, KY.—F. D. Hart, Jr.
PITTSBURG, PA.—J. S. Crider, James F. Cummings, H. S. Smith, Frank H. Taylor, Arthur Warren, H. E. Webb, Alexander Jay Wurts.
PROVIDENCE, R. I.—L. W. Downes, A. W. Hutchins, F. N. Phillips.
QUEBEC, CAN.—F. H. Badger, Jr.
QUINCY, ILL.—H. O. Channon, C. G. Comstock, Thomas Holl.
RACINE, WIS.—P. H. Korst.
RED OAK, IA.—A. M. Miller.
ROCHESTER, N. Y.—George A. Redman, Mrs. Redman.
ST. JOSEPH, MICH.—W. Worth Bean, Jr.

ST. JOSEPH, MO.—Charles E. Roehl.
ST. PAUL, MINN.—H. J. Gille, C. R. Smith.
ST. LOUIS, MO.—E. H. Abadie, A. C. Garrison, H. H. Humphrey, J. E. Johannsson, W. A. Layman, E. V. Matlack, Edwin S. Pillsbury, Geo. D. Rosenthal, Herbert A. Wagner, H. S. Wells, C. Boettcher, E. S. Brinkman.
ST. PAUL, MINN.—Channing T. Gage.
SAULT STE. MARIE, MICH.—W. F. Kingan.
SAVANNAH, GA.—T. P. Keck.
SCHENECTADY, N. Y.—W. S. Andrews.
SEWICKLEY, PA.—J. W. Uptegraff, E. P. Young.
SHELBYVILLE, ILL.—E. F. Wells, R. S. Wells.
SIOUX CITY, IA.—C. E. Woodrow.
SPRINGFIELD, ILL.—Eugene Holcomb.
SPRINGFIELD, MASS.—H. S. Anderson.
SPRINGFIELD, O.—J. H. Miller.
STAMFORD, CONN.—Ronald Crawford.
STEUBENVILLE, O.—J. W. Hull.
SYRACUSE, N. Y.—H. H. Crowell.
TOKYO, JAPAN.—I. Fujioka.
TOLEDO, O.—W. S. Smith.
TORONTO, CAN.—F. C. Armstrong.
WARREN, O.—Elmer W. Gillmer, W. D. Packard.
WASHINGTON, D. C.—J. B. Lukes.
WATSEKA, ILL.—H. J. Frith.
WEST CHESTER, PA.—James E. Pyle.
WILKINSBURG, PA.—John J. Jennings.
WILLIAMSPORT, PA.—Ernest H. Davis, G. E. Wendle.
WILMINGTON, DEL.—Samuel N. Trump, C. R. Van Trump.
WINDSOR, CONN.—M. E. Baird.

SOCIETY & CLUB NOTES

The Trip of the "Northwest."

After the Chicago convention of the National Electric Light Association, about 100 of the delegates and ladies gathered on board the fine lake steamer "Northwest," which left Chicago on Friday, June 10, at 12.30 noon, to attend the convention of the Northwestern Electrical Association. Milwaukee was reached at 6 p. m. when the party was increased by further accessions from the Wisconsin electrical ranks. The trip promises to be pleasant and interesting.

PERSONAL

Mr. Frank J. Sprague.

It will be of interest to the general public, hardly less than to the electrical fraternity, to know that Lieut. Frank J. Sprague, who has for the last six weeks been confined to his house, and in great suffering, from a severe injury to his right eye, is in a fair way to recovery. Nearly two months ago a piece of the eyeglass Mr. Sprague was wearing was accidentally forced into the ball of the eye, and Mr. Sprague had to remain for some weeks under the care of a specialist. Being very anxious to push forward to definite shape the Volunteer Corps of Electrical Engineers, which he offered some time ago to organize for early service at the front, Mr. Sprague imprudently went to Washington, where he caught cold in the injured eye. Severe complications set in, along with iritis, and for some time it was feared that blindness was inevitable. This danger, however, seems to have passed, and there is every prospect that Mr. Sprague will soon be able to renew his active part, both in the affairs of the company with which he is identified and the formation of a fighting corps that should fill a place of its own in the war resources of the Government.

JAN SZCEPANIK, whose electrophotoscope was recently brought to notice, is said to have a new invention in which he utilizes photography and electricity in weaving so as to furnish designs for tapestries and to produce, for example, silk handkerchiefs with in-woven picture or portrait done on the spot.

LIEUT. E. B. IVES has been gazetted Captain the First Regiment of United States Volunteer Engineers, in which his military experience and especially his familiarity with signal corps work will make him very useful.

MR. G. C. SIMS, who is now on the U. S. S. Vulcan, as noted recently in our columns, was on May 28 raised to the highest grade in the Engineer Corps, namely, that of Chief Engineer in the United States Navy, with the relative rank of Lieutenant.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued May 31, 1898.

Alarms and Signals:—

ELECTRICAL SIGNALING SYSTEM AND APPARATUS. W. F. Banks, Milford, Conn., 604,712. Filed Oct. 1, 1896. Designed for "municipal" signaling systems. Details of construction.

SIGNAL FOR ELECTRIC RAILWAYS. W. H. Jordan, Brooklyn, N. Y., 604,866. Filed Feb. 16, 1897. A crossing signal designed to be operated by a moving car.

Dynamos and Motors:

ELECTRIC MOTOR OR DYNAMO. A. L. Riker, New York, 604,842. Filed Nov. 27, 1897. Embodies an enclosing casing having at one end an extension enclosing and supporting the brushes, and having a door in one side thereof to give access to them.

FORMER FOR WINDING ARMATURE COILS. A. L. Riker, New York, 604,843. Filed Nov. 19, 1897. Comprises two parts having a winding space between them, and winding channels in each part transverse to the plane of the winding space, those in one part being on the face of the former, and those in the other part in the rear thereof.

Lamps and Appurtenances:—

RHEOSTAT FOR ELECTRIC LAMPS. R. H. & F. H. WAPPLER, New York, 604,949. Filed Sept. 20, 1897. Adapted to be placed in the socket of an incandescent lamp to render it self-regulating.

Miscellaneous:—

ELECTRICAL BELT. A. J. Taylor, Vineland, N. J., 604,806. Filed April 12, 1898. An electro-galvanic belt comprising a sheath, hook-plates attached thereto, hinge-plates having electrical connection with the hook-plates, battery electrodes hinged to the hinge-plates and provided with removable fibrous pads, and a battery detachably connected to the hook-plates within the sheath.

SAFETY DEVICE FOR ELECTRIC CARRIAGES. R. T. D. Brougham and W. C. Bersey, London, England, 604,874. Filed Dec. 13, 1897. Means to prevent unauthorized persons from starting electrically-propelled carriages when left by the driver.

Railways and Appliances:—

ELECTRIC RAILWAY. J. H. Guest, Boston, Mass., 604,747. Filed Oct. 20, 1896. Comprises a trough-shaped contact-rail forming a working conductor, having supplemental contact-rails within the same, metal cross pins mounted on the sides of the trough and passing through the rails but insulated from them, and a filling of insulating cement in which rails and pins are anchored.

ELECTRIC RAILWAY. F. D. Sweet, Elyria, Ohio, 604,911. Filed Nov. 4, 1897. The continuous conductor is dispensed with and in its place a series of contact rollers placed at suitable intervals engage consecutively with a runner carried by the car.

AUTOMATIC CURRENT DISTRIBUTOR FOR ELECTRIC RAILWAYS. J. Clarent and O. Vuilleumier, Paris, France, 604,968. Filed May 4, 1897. Details of construction.

SWITCHING DEVICE AND CIRCUIT ARRANGEMENT FOR ELECTRICALLY-PROPELLED VEHICLES. E. B. W. Reichel, Berlin, Germany, 605,013. Filed Jan. 10, 1898. Embodies a contact-piece electrically connected with and actuated by the trolley arm, and adapted to be electrically engaged only when the trolley arm is in engagement with the trolley conductor.

ELECTRIC SWITCH FOR USE WITH ELECTRICALLY PROPELLED VEHICLES OR LOCOMOTIVES, ETC. A. T. Snell and C. E. Grove, London, England, 605,023. Filed Oct. 8, 1897. A compound switch comprising a starting switch and a controlling switch for coupling the motors in different relations, and mechanism for imparting an intermittent movement to the controlling switch from the starting switch.

THIRD RAIL UNDERGROUND ELECTRIC RAILWAY SYSTEM. L. E. Walkins, Springfield, Mass., 605,066. Filed Aug. 21, 1897. The third rail is contained within a conduit.

Telegraphs:—

PNEUMATIC ATTACHMENT FOR TELEGRAPH KEYS. W. J. Lieb, Pratt, Minn., 604,770. Filed April 15, 1897. Comprises an outer wall, a diaphragm, means for securing the device to a key button, and a tube leading into the air-chamber formed by the outer wall and the diaphragm.

Classified Digest of U. S. Electrical Patents Issued June 7, 1898.

Alarms and Signals:—

HEAT OR COLD INDICATOR. E. B. Petersen, Kearney, N. J., 605,129. Filed Aug. 11, 1897. Details of construction.

CALL BOX SYSTEM. E. E. Salisbury and A. E. Dean, Tacoma, Wash., 605,345. Filed June 22, 1897. A call box system in which a telephone is utilized.

SIGNALING DEVICE. F. B. Taylor, E. E. Salisbury and A. E. Dean, Tacoma, Wash., 605,358. Filed July 23, 1897. Means to enable an operator at a central office to automatically turn in any one of a number of outlying call boxes desired on a single circuit and at the same time signal the subscriber without disturbing any other subscriber.

RAILWAY SIGNALING AND SWITCHING APPARATUS. J. D. Taylor, Chillicothe, Ohio, 605,359. Filed March 24, 1897. An interlocking apparatus having means for preventing a lever changing its position in either direction before the track-switch has made its complete movement.

FOG SIGNALING APPARATUS FOR RAILWAYS. H. Tomlins, London, England, 605,361. Filed Nov. 22, 1897. Means to render

the operation and firing of the fog signaling apparatus automatically dependent on the position of the semaphore signal.

Batteries, Secondary:—

CONNECTOR FOR STORAGE BATTERY PLATES. G. Hart, Detroit, Mich., 605,424. Filed Jan. 13, 1898. Comprises an insulating base-bar, a lead plate superimposed upon it, connector plates alternately extending in opposite directions and resting at one end upon the lead plate, and screws passing through the connector plates and the superimposed lead plate into the insulating base-bar.

Conductors, Conduits and Insulators:—

INSULATOR. F. M. Locke, Victor, N. Y., 605,109. Filed April 23, 1898. Constructed of two or more porcelain parts fitted one into the other, and secured together, the inner part extending down to a point adjacent to the cross-arm, or resting upon the cross-arm, and forming a sleeve for the purpose of protecting the pin from static discharge of the current around the insulator.

INSULATOR. R. D. Mershon, Colorado Springs, Colo., 605,256. Filed Feb. 14, 1898. An insulator for high tension circuits having a long tubular petticoat adjacent to the supporting pin, and a short outer petticoat of much greater diameter, the edge of which is approximately the same striking distance from the cross-arm and the supporting pin.

Distribution:—

ELECTRIC TRANSFORMER. J. J. Bellman and C. T. Rittenhouse, New York, 605,194. Filed June 29, 1897. Comprises a ferromagnetic field built up of integral plates so mortised that when the plates are properly assembled the core of the magnetic field will be approximately circular in cross-section.

Electro-Metallurgy:—

PROCESS OF PRODUCING ALUMINUM SULFID AND REDUCING SAME TO METALLIC STATE. H. S. Blackmore, Mt. Vernon, N. Y., 605,380. Filed July 22, 1896. Consists in simultaneously convertng insoluble aluminum oxid into soluble aluminum oxid sulfid while in a molten bath and dissociating the soluble aluminum sulfid by electrolytical action.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. W. Hochhausen, Brooklyn, N. Y., 605,228. Filed Jan. 22, 1897. Details of construction.

SAFETY LOCK FOR INCANDESCENT LAMPS. E. Faller and H. Herbstritt, San Francisco, Cal., 605,279. Filed Sept. 17, 1897. Designed to prevent the surreptitious removal and stealing of incandescent light globes.

Measurement:

INSTRUMENT WINDING DEVICE. H. H. Wait, Chicago, Ill., 605,154. Filed Dec. 14, 1896. Comprises a chuck formed in two parts which are adapted to engage a core, each of the parts being provided with a lip, the lips being oppositely placed, the opposing surfaces of the lips diverging outwardly from the core receiving surfaces of the chuck.

Miscellaneous:—

INDUCTION COIL. A. L. Bogart, Jamaica, N. Y., 605,174. Filed April 22, 1897. A Ruhmkorff coil, combining the primary and secondary coils, a condenser arranged in the same plane therewith and partially enclosing the same.

ELECTRICAL VALVE CONTROLLING DEVICE. A. E. Colgate, New York, 605,197. Filed May 28, 1896. Employs a clock movement as the automatic circuit-controller for the whistle and a modified form of magnet for controlling the circuit to the clock movement and an improved weatherproof hand switch for controlling the apparatus at will.

ELECTRICAL APPARATUS FOR CHARGING FURNACES. J. P. Eck, Muncie, Ind., 605,090. Filed Aug. 12, 1897. Comprises two charging tracks, two trucks adapted to run thereon, a shaft for connecting the trucks, a hollow charging bar, an operating rod journaled in the ends of the charging bar, a cam formed at one end of the operating rod adapted to engage the shank of the charging pan.

Railways and Appliances:—

RAIL BOND. G. Moffat, New York, 605,115. Filed Feb. 24, 1898. Comprises two telescopically connected members, the members adapted for engagement with openings in adjacent rail sections.

TROLLEY SWITCH. J. H. Vanasselt, Seattle, Wash., 605,211. Filed Oct. 2, 1897. Comprises a switch plate provided with a keeper, a guide arranged at the under side of the switch plate and normally bearing against the guide, and a latch also arranged at the under side of the plate and connected with the switch point and adapted to engage the keeper and hold the switch point away from the guide.

TROLLEY WIRE HANGER. G. E. Johnson, Los Angeles, Cal., 605,251. Filed Aug. 19, 1896. Comprises an interiorly-screw-threaded cap; a plug of insulating material exteriorly screw-theaded and screwed on to the cap; a trolley-wire hanger having its stud secured in the plug; the rim of the cap being beveled outward and downward away from the plug to form a drip edge.

MOUNTING FOR THIRD RAILS. S. H. Short, Cleveland, Ohio, 605,260. Filed Nov. 5, 1897. A supporting bar for a third rail having bell-shaped castings at the end, insulating material arranged in the castings, and supporting standards arranged to be received in the insulating material.

THIRD RAIL FOR ELECTRIC RAILWAYS. S. H. Short, Cleveland, Ohio, 605,261. Filed Nov. 5, 1897. Combines with standards, a bar supported by but insulated from the standards, a third rail supported upon the bar, the rail presenting a side surface for contact with the collector and a strip lengthwise upon the rail and extending over the top edges thereof.

CONTROLLER. T. Von Zweigbergk, Cleveland, Ohio, 605,304. Filed Feb. 23, 1898. Combines with the controller shaft, a collar tightly surrounding the shaft and a trough below the collar and adapted to receive water passing from it and convey it beyond the controller.

ELECTRIC RAILWAY SYSTEM. W. Lawrence, New York, 605,317. Filed Dec. 1, 1897. Surface contact system.

TROLLEY CONNECTION FOR ELECTRIC CARS. J. G. McLaughlin, Brooklyn, N. Y., 605,326. Filed Dec. 28, 1897. Comprises a trolley pole, a swinging frame having cheeks extending upward above and beyond the extremity of the trolley pole, and a wheel mounted between the upwardly projecting cheeks of the swinging frame.

Switches, Cut-Outs, Etc:—

ELECTRIC SWITCH. C. C. Badeau, Schenectady, N. Y., 605,067. Filed Sept. 17, 1897. Knife switch for switchboard use.

ELECTRIC SELECTOR SYSTEM. T. C. Drake, Malta, Ohio, 605,309. Filed Feb. 26, 1897. Consists of step-by-step and unison mechanism which is operated and controlled in series.

Telephones:—

TELEPHONE SYSTEM. E. W. Ham, Worcester, Mass., 605,097. Filed Aug. 22, 1897. Intercommunicating telephone system.

TELEPHONE HOLDER. J. T. Moore, Minneapolis, Minn., 605,294. Filed Aug. 24, 1897. A pivotally supported lever, having a balance weight on one end and a telephone receiver clasp on the other end, with a telephone switch operating connection.

TELEPHONE SYSTEM. R. T. Reid and J. L. McDonnell, Tacoma, Wash., 605,341. Filed Sept. 25, 1897. Provides a simple and effectual lock-out device whereby the line can be restricted to the use of any one subscriber to the exclusion of the others.

THE STOCK MARKET

War a Waning Factor.

It seems to be assumed that war is now cutting little figure in the general course of events, and that Spain will be smashed anyhow, sooner or later, without too heavy an expenditure, and with some compensation in the shape of new territory and favoring markets. The stock market last week in 174 stocks saw rises in 95, declines in 62 and no change in 17. An event showing the drift of popular thought was the great Republican victory in Oregon on a flat, straight out, stand up fight for the gold platform, offsetting any silver talk in the Senate. Just at the moment, there is interest in the issue of the first war loan and the effect of war taxes. The grain outlook is good for railroad freights, although the estimates of 637,000,000 bushels of wheat or 200,000,000 more than last year, do not promise the maintenance of high prices.

During the week, 13,119 shares of Western Union were sold up to 92⅜, closing at 91⅝. Of General Electric 33,395 shares were sold closing at 38¾. In Boston, American Bell Telephone reached 275 on sale of about as many shares.

OBITUARY

Fred. A. Noll.

It is with extreme regret that we record the death of Mr. Fred. A. Noll, at the early age of 41. He was an active member of a family which has been prominently connected with the development of electricity in this vicinity, and had a remarkably wide circle of acquaintance in his chosen field of work. He was connected with the Edison parent company almost from the time of its formation, and had charge of its supply department. Later on, he was connected with the Edison Co. for Isolated Lighting, and still later with the Edison United Mfg. Co. He then became associated with the New York Edison Illuminating Co., having charge of the supply department, and he held the same post with the New York Electrical Equipment Co., which took over that branch. At the time of his death he was on the staff of the Sprague (Interior Conduit and Insulation) Co. It may be doubted whether anyone was better informed in regard to the various appliances used in electrical distribution and consumption. He leaves a widow, to whom and to the other members and relatives of the family universal sympathy and regret is extended.

HOUSTON, TEX. The city attorney has advised the City Council that the present contract with the Citizens' Electric Light and Power Company is not binding, in case the city wants to operate its own plant. The contract runs for ten years from 1894.

AMERICAN ELECTRICAL DIRECTORY, successor to the Standard Electrical Directory, is an excellent publication, giving statistics, complete and detailed, of electric lighting and railway work in America. It is issued by Mr. E. L. Powers, who is aiming to make it as accurate as possible.

MECHANICAL

Electric Mine Pumps.

DURING the past few years the greater number of pumps installed in mines have been electric, and, in fact, machines of this style are fast supplanting the steam pumps previously installed.

Many improvements in the construction of this class of machinery have fulfilled the demand for a pump embodying economy and convenience.

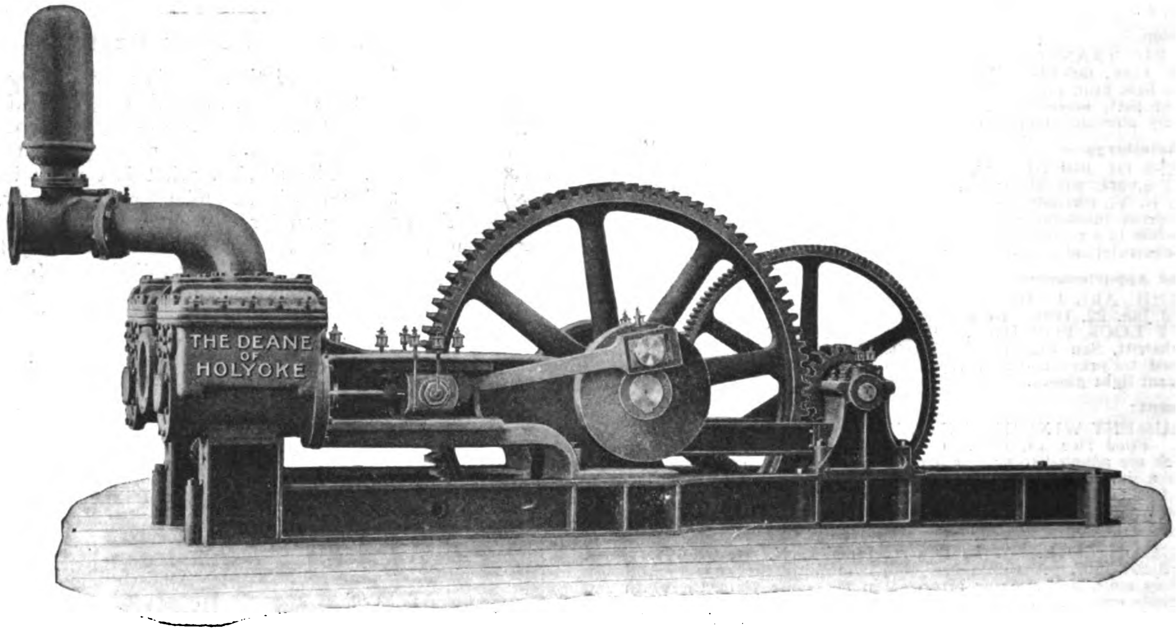


FIG. 1.—DEANE STEAM PUMP, CAPACITY 1,200 GALLONS PER MINUTE, AT HELENA MONT.

The operating of steam pumps in mines necessitates carrying the live steam from the boilers, which must needs be located at the top of the shaft, through long lengths of pipe to the pumps, which are located from 100 to 1,000 feet below. The large first cost of such an installation is apparent; it further means a loss of steam by condensation, and an equally as expensive means must be provided to care for the exhaust steam. The latter is not only a factor of much expense, but often fills the mine with a vapor, causing an intense heat, which is unbearable to those engaged in the work. This, of course, is obviated by the use of electric pumps, another advantage of which is the ease with which they may be moved in the shaft, depending upon the height of water. The machines shown are furnished with heavy iron bases, or bed plates, extending the entire length, which enables the apparatus to be raised or lowered at will without interfering with the alignment.

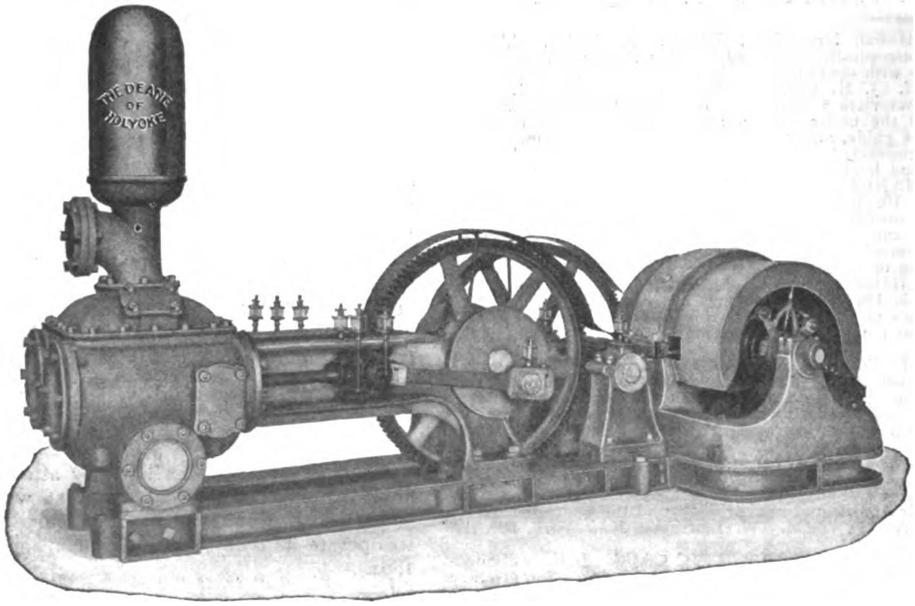

FIG. 2.—DEANE STEAM PUMP CONNECTED TO MOTOR; CAPACITY 400 GALLONS PER MINUTE, AT HELENA, MONT.

The Deane Steam Pump Company, of Holyoke, Mass., have been builders of mine pumping machinery for many years, and their line of patterns for steam and electric pumps is large.. In the accompanying illustrations are shown two Deane electric mine pumps recently put in operation at the United States Smelting Company's mine, near Helena, Mont. Fig. 1 shows a pump arranged for a motor and has a capacity of 1,200 gallons per minute. Fig. 2 is complete with motor and has a capacity of 400 gallons per minute.

Both of these are of the duplex pattern, embodying all modern features; the water ways are ample and furnished with means for inspection of interior parts; all bearings are lined with genuine babbitt and the gearing is of hard iron accurately cut to a true pitch; parts subjected to constant strain are cast from steel, and means for taking up wear are provided. Everything is of the strongest and best.

TRADE NOTES & NOVELTIES

General Electric Co.'s Supply Headquarters in Chicago.

IN facilitating its relations with that large class of its customers located in the Middle and Northwestern States and dealing directly with its Chicago sales office, the General Electric Company has found the large warehouse and repair shop which it has established in that city of the greatest value. The warehouse and repair shop occupy a commodious and well-lighted six-story and basement building, abutting on the main lines of three great railroads—the Chicago & North-Western, the Baltimore & Ohio and the Wisconsin Central. It is also on the Belt line, which connects with all the other railroads radiating from Chicago. From these, into a special spur by the side of the warehouse, the cars of any of the roads may be switched, and the warehouse has thus the great advantage of shipment and reception of goods in carload lots, to or from any point in the Union.

The top, or sixth floor, is devoted to the storage of unbroken packages of arc lamp globes, porcelain and glass insulators, insulator pins and cross-arms, armatures of the older types of machines, etc. On the fifth floor is stored a stock of incandescent lamps in original packages ready for immediate shipment, fan motors, arc lamp globes in broken lots, arc lamp carbons, etc. At the time of writing this the incandescent lamps of various candle powers, voltages, etc., in stock numbered roughly about 500,000, which number is kept constantly on hand by weekly shipments from the Edison Lamp Works, of Harrison, N. J.

FIG. 1.—CHICAGO STOREHOUSE AND REPAIR SHOP, GENERAL ELECTRIC COMPANY.

The fourth and third floors are laid out in floor bins and wall cupboards, the latter divided into pigeon holes of various sizes. Each bin and each pigeon hole has the catalogue number of the device or part it contains and so well is all arranged that a boy could fill from the bins and cupboards any order for supplies, large or small. On the fourth floor are the larger wiring supplies and parts, arc lamps—single and double carbon series and open and enclosed arcs for direct or alternating circuits; car resistances, and meters and type "H" transformers of all sizes, in the original factory boxes ready for re-shipment at the shortest notice. In the bins on the third floor are the smaller wiring supplies and parts. To attempt to enumerate all the devices kept in stock in this warehouse would be to transcribe the supply catalogues of the General Electric Company; suffice it to say, that no order, however large or insignificant, but can be filled from this stock.

The second floor contains the repair shop, fully equipped with lathes, planers, drill presses and shapers, all driven by electric motors. The front part of this room is given up to the armature rewinding department. On this floor is located also an elaborate meter, lamp and transformer testing department, as well as a dip room and polishing room for re-finishing arc lamp casings, etc. On the first floor are stored all the heavy machines—generators, motors and the larger sized transformers. This is also the shipping and receiving room for all the stock, and one corner is devoted to the office, while in the rear is a small carpenter shop, with planer and a circular saw driven by a 5 h. p. motor. An overhead track equipped with traveling chain hoists runs above this floor and out over both railroad tracks and the street and greatly facilitates the shipment or reception of the cases of supplies or apparatus. Along one side run a number of large bins, each labeled with the name of a railroad or express line. In these bins are placed the cases for shipment, so that they may be shipped out rapidly without confusion or mistake. By a special arrangement with the express companies, four shipments, the last at 6 p. m., are made daily. Thus express orders leave the warehouse the day they are received at the office.

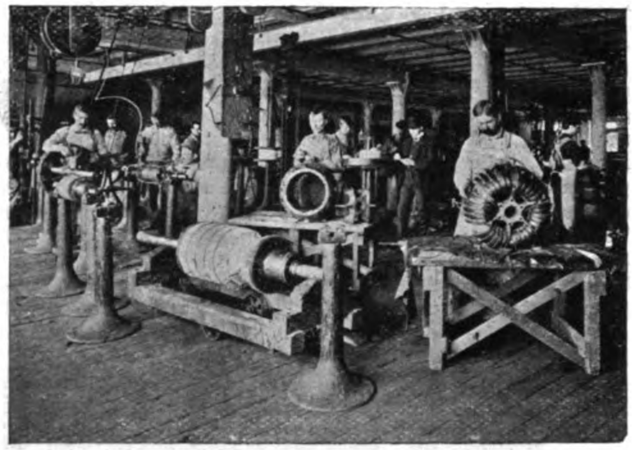

FIG. 2.—ARMATURE REWINDING DEPARTMENT.

The basement contains the power plant, consisting of two 80 h. p. boilers and two horizontal engines, one of 100 h. p., used for dynamo testing purposes, the other a 50 h. p. engine belted to a direct current machine, from which the lighting and power current used in the building is supplied, and to a 20 k. w. alternator, used for meter and other testing purposes. The basement also contains a boiler feed pump, a water heater, a large fire pump, four large steam-heated ovens for baking armatures and dynamo field coils, and a switchboard divided into three sections, equipped for testing high tension series arc machines, direct current low tension machines and alternating testing work. The load for the first consists of a bank of arc lamps, also in the basement; for the second, a large water rheostat under the

FIG. 3.—METER AND LAMP TESTING DEPARTMENT.

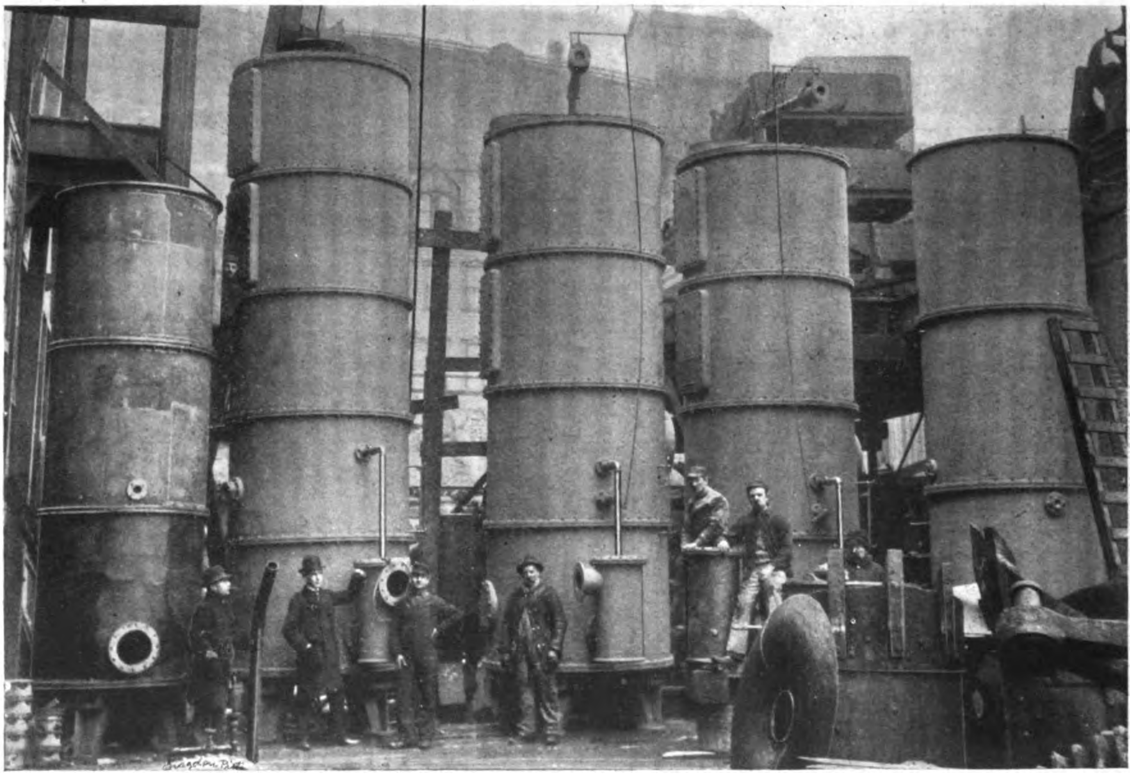
sidewalk, and for the alternating section a large bank of incandescent lamps on the second floor. Beneath the sidewalk is kept a large stock of insulating oil for transformers. The different floors are connected by a four-ton elevator.

The repair shop is in charge of Mr. L. G. Crawford. The warehouse was arranged by and is under the care of Mr. George M. Ellis.

Pittsburg Feed-Water Heaters and Purifiers.

THE attention of steam users is called to the claims made for the Pittsburg feed water heaters and purifiers, both of the open and closed types, and for which James Bonar & Co., Pittsburg, are general sales agents. The open heaters, as shown by accompanying illustrations, which are a lot recently manufactured for one of the Carnegie and Shenango Valley Steel Company's plants, are cylindrical in form, and are made in various sizes, these in the illustration being from 18 to 23 feet in height and from 5 to 6 feet in diameter, the largest being rated at 5,000 h. p.

These heaters are manufactured in sizes from 50 to 6,000 h. p., and there are now over 60,000 h. p. in use. The shells, as well as the interior mechanism, are nearly in all cases made from cast-iron, except where steel is preferred, it being considered that cast metal is less liable to corrosion from the action of acids than rolled steel or iron. The internal mechanism consists of a spraying device located at the top, a series of settling pans circular in form, but loosely attached to a central hollow shaft, and floats for operating the valves in the supply pipes. The cold water is admitted at the top, through a pipe, which enters at the centre of the head, and which branches near the head into a number of radiating brass pipes, which are perforated on the sides, with the outer end closed. By this means the water is distributed evenly in a spray over the whole surface of the upper pan, which is provided with perforations, through which the water flows in small streams to the pan below, then over the edges of the succeeding series of pans, until it reaches the bottom part of the heater. The exhaust steam is admitted by a pipe through the sides of the heater, below the pans and ascends along the outer edge of the pans and through the hollow shaft, which in turn is perforated between each series of pans, so that the steam passes over the surface of each pan, and rises along the outer edges to the discharge pipe at the top, imparting its heat to the finely sub-divided water in its passage. On account of rapid condensation and ample space there is no back pressure. The sediment is deposited in the pans and at the bottom of the heater. The pans are each independent of the other, and, being mounted loosely on the central shaft, can be readily turned and every part brought before a side door for cleaning or inspection. As a means of purification, there are placed in the base of the heater, just above the normal water level, two perforated blow-off pipes, bent in the form of a horseshoe, and so arranged that the oil or other impurities that may float on the surface are skimmed off and discharged. A sensitive float, consisting of a copper ball, is provided which operates a valve in the supply pipe at the top and thus regulates the supply of water. As a further precaution to prevent impurities from entering the boiler, the pump suction pipe is attached to the side of a small auxiliary cylinder, called the oil separator. This cylinder has a large water connection with the supply in the base of the shell, but below the surface of the water and above the bottom of the heater. This is much larger than the suction pipe, which enters the cylinder below the surface of the water, while a second pipe connects the top of the cylinder with steam space in the heater, so that should the water for any cause fall to a level with the suction pipe, it would draw steam instead of water, and so prevent its drawing in any floating oil that might possibly have gained entrance to the cylinder. The main shell and the auxiliary cylinder are each provided with a blow-off pipe at the bottom, by which means any sediment is readily removed. Large cleaning doors and manholes are also provided. A thermometer and water gauge complete the essential parts of the device.



PITTSBURG FEED WATER HEATERS AND PURIFIERS.

The manufacturing facilities controlled by this firm are ample and orders can be filled in from ten days to two weeks.

In the closed type of heaters the water passes in pipes and is heated by the surrounding steam. These are manufactured in various shapes, both with curved and straight pipes, opening into chambers. Heaters of either type are made in special form to suit peculiar locations or to meet the views of intending purchasers. All the heaters are built under the supervision of Mr. J. E. Schleiper, inventor and patentee.

POSTAL TELEGRAPH BOYS now wear blue uniforms instead of gray, the cloth resembling in color that used for the army.

New Enclosed Lamps of the Manhattan Co.

DURING the past four years the Manhattan General Construction Company have been gathering together all of the improvements possible on their old lamp, and have delayed until now changing even in the slightest detail the old structure, as it was so generally adopted by central stations that entire uniformity of parts was essential. While the Manhattan company still furnish their old types of lamps, they have brought out a line of new improved types, which are designed to burn in multiple on direct-current circuits of from 90 to 250 volts; in series on circuits of from 200 to 600 volts, and on alternating current circuits of any frequency from 90 to 130 volts.

While retaining all of the well-known and valuable features of the old lamp, they have combined many new and radical departures. The principal defects which experience showed to exist in the old lamps were:

First, length of 36 inches, which has been reduced to 29 inches.

FIG. 1.

FIG. 2.

FIG. 3.

Second, on the old lamp it was necessary in retrimming to remove entirely from the lamp the spider holding the pan, the inner bulb, the gas check plug, the carbon and the sheath, all of which either had to be held in the hand or laid down while replacing carbons and cleaning the bulb. In trimming, both hands had to be used, and when the lamp was hot this method became a hardship. To provide, however, for cases where stations preferred to obtain entire uniformity of all parts required to be handled by trimmers, it has been arranged so that the new lamp may be furnished to take the old style of trim or new style of trim may be furnished for old lamps now in service. The trim is removed in shipment.

Third—In the old lamp the outer globe is stationary and is a fixture on the body of the lamp. This saves handling, and many central stations claim that the saving thus made in breakage of outer globes nearly pays for renewal of inner bulbs, and this feature has been retained in the new lamp.

Fourth—In all other types of lamps the outer globe is lowered to give access to parts in trimming. In the new Manhattan lamp there has been introduced the novel feature of lowering the bulb down through the opening in the bottom of the outer globe on double telescoping rods, as shown in Fig. 3. The inner bulb and carbons are thus brought in full view below the lamp, and after retrimming the device on being raised automatically locks in position. To lower the trimming device it is only necessary to press the knob on the bottom of the lamp. The carbon sheath is removed as heretofore, but the current is fed to the upper carbon directly through the sheath in place of a separate brush box, as formerly. Contact between the sheath and the inner tube is made by means of metal balls contained in the sheath. Magnetism automatically attracts these balls against the sides of the inner tube and assures perfect contact.

Fifth—It is perhaps not sufficiently well understood that one of the secrets of the life of the carbon is largely dependent on the style of closure of the top of the inner bulb. The cap used in the new Manhattan lamp is provided with a gas chamber which materially lengthens the life. This cap is made under the patents of L. B. Marks and Moses S. Okun, and is said to cover every form of cap having a gas chamber and lateral movement.

Sixth—In the old Manhattan lamp one of its great disadvantages was that to adjust the current it was necessary to take out the pan and bulb, take off the globe and yoke, take the lamp down from its hanger, take off the top plate, undo the wire connections, remove the rheostat and take off the shell from above. In the new Manhattan lamp, the mechanism shell may be lowered while the lamp hangs in position, by removing the trim and the outer globe and giving the central cylinder a quarter turn, when the shell may be removed and the current adjustment of the lamp can be changed.

The adjustment of the rheostat for voltage may be made by loosening the set screws and lowering the split canopy at the top, as shown in Fig. 4 at letter A.

Seventh—While the great claim for Manhattan lamp has always been its simplicity, it will now be found that all the mechanism below the armature has been dispensed with and that the only moving part in the lamp is the armature, inside of which, however, is a ball clutch. The clutch of the old lamp consists of four rings passing through slots in the armature, and the whole lamp had to be taken down and apart to reach the clutch. For this four balls have been substituted, which ride between the inclined surface of the inside of the armature and openings in the central brass tube. The armature and the clutch may be removed from the lamp while it hangs in position by undoing one nut.

Eighth—In the old lamp the part requiring most frequent renewal and which was a general cause for repairs was the brush box through which the current was fed to the upper carbon This has been entirely eliminated from the new lamp.

Ninth—One of the sources of danger to short arc lamps has been that the arc is so close to the mechanism there is a likelihood of burning out the magnet. This has been provided against by the use of a ventilated magnet, and a current of air is constantly passing between the magnet and the central tube.

Tenth—The steady burning of the old type lamp depended absolutely upon the perfection of the air chamber, requiring great nicety of manufacture. It was impossible to make the lamps altogether interchangeable. In the new lamp there is no such chamber, and a loose fit is maintained between all of the parts. In addition to the air chamber in which the armature works in the old lamp, a further chamber was provided around the clutch, making it necessary to take the shell off in a most inconvenient manner; and great care had to be used in replacing the insulation at this point. This made the old lamp most difficult to assemble, but it has also been remedied in the new lamp.

Eleventh—In the old lamp proper assembling was the most important feature. Unless it was done with accuracy and the lamp was lined up exactly, it would not burn properly, and it was almost impossible for users of the lamp to take it apart and put together again without special tools. All of the parts were assembled with driving fits, whereas in the new lamp all of the parts are loose fits and may be removed with the fingers; and to entirely remove all of the parts of the lamp it is only necessary to remove two nuts.

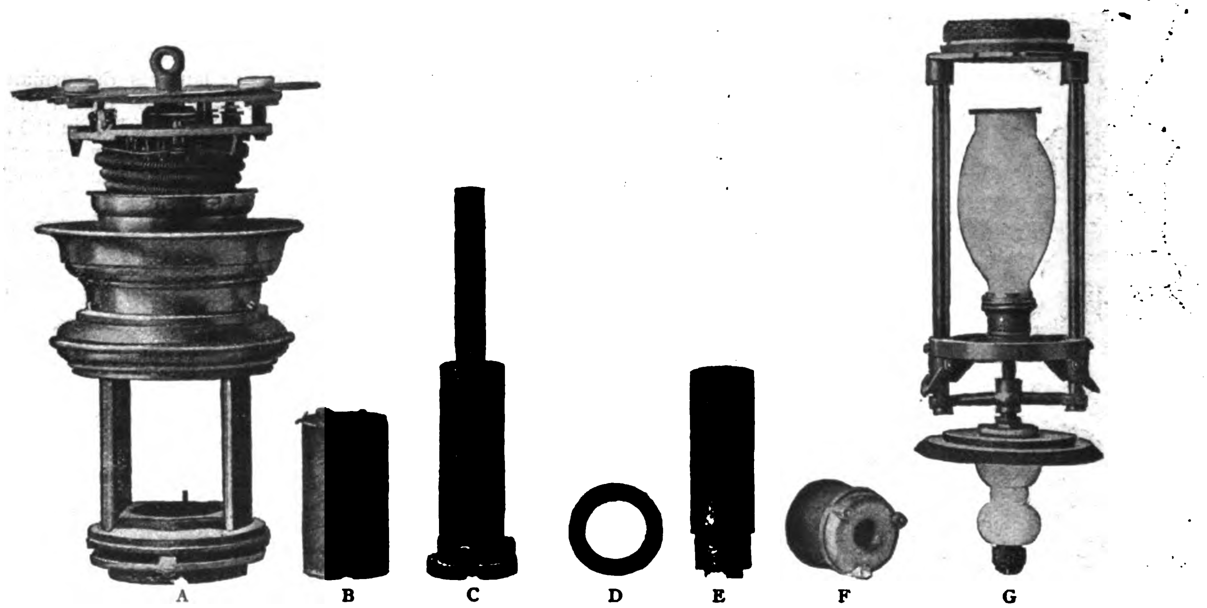
In the old lamp, to take out the magnet, it is necessary to remove the globe and the lower frame, take the lamp down, take off hanger, nut, top plate, rheostat, outer shell, inner air chamber shell and brush box, then to remove four screws and insulating washer from casing holding outer globe, then remove clutch by removing two screws holding clutch pan to the armature, loosen set screw and take out the magnet frame plug (which was a driving fit into the magnet frame), remove armature from top, then take out magnet tube (which was also a driving fit into the magnet frame). This central tube, forming the air chamber of the lamp, was most liable to be damaged in removing and replacing, and if not returned perfectly true would cause the lamp to stick. The number of operations to assemble the lamp is therefore reduced from 20 to 6.

In the new lamp, to remove the magnet, the lamp may remain hanging in position (see Fig. 4), taking off globes and frame G, unscrewing cap F, when there may be taken out the armature E, then unscrewing the nut D, and the central tube C and the magnet B may be slipped out of the frame A, and every part of the lamp is separated. The lamp may be assembled by the reverse operations. In taking apart the lamp no insulation of any kind is disturbed.

By an improvement in the electrical and mechanical design of the magnet and armature, the new lamp will be found to burn within very narrow limits, and with great steadiness.

The rapid extension in this country and abroad of the use of circuits of from 220 to 600 volts has caused a large demand for lamps to burn in multiple on such circuits. The new type Manhattan lamp has been designed for such service, and the mechanism of the lamp is exactly the same as the lamp above described, and the same lamp can be transferred from a 110 to a 220-volt circuit by the substitution of another coil and rheostat and a change of the nut holding the armature.

The same standard new type Manhattan lamp is also arranged to burn two or more in series on circuits of from 200 to 600 volts by a change of the magnet coil. These lamps will be furnished with a special form of separate rheostat for each lamp, which can be cut in to take the place of a lamp when one lamp in the series is cut out, without disturbing the balance of the series.



A B C D E F G

FIG. 4.

The new type Manhattan alternating enclosed arc lamp contains a different form of mechanism, as shown in the cut, but the trimming device, outer globe, gas check plug, carbon sheath and shell are the same as used on the direct-current lamp, and these parts of the two lamps are interchangeable.

The trim of the old type Manhattan lamp is also interchangeable with that of the new alternating lamp. While the mechanism is of a different type from that of the standard Manhattan direct-current lamp, the clutch is the same, and it will be noted that the entire mechanism consists of a magnet and core, stationary central tube containing the ball clutch and a dash pot. There have been eliminated all clockwork, toggle clutches, carbon rods, walking beams, racks, levers, etc. Access to the mechanism may be had while the lamp hangs in position by removing the globe and trim and giving the mechanism shell a quarter turn. The trimming device is removed in shipping.

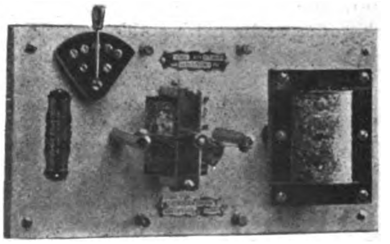
The Manhattan company state that they have been working on this lamp for nearly a year, and have put it through continuous commercial tests, and do not hesitate to state that the lamp will maintain the high reputation of the company. It is economical and reliable. It starts up quickly and without chattering, will run without variation of current and quietly from 100 to 130 volts where such variation is found to exist without readjustment. The lamp will burn 100 hours with one 9½x½ inch upper and one 6x½ inch lower carbon, and the unburned portion of the upper may be used as a lower for the next run. On circuits of 100 volts and 6 amperes the lamp consumes 450 watts. The length of the lamp is 29 inches.

The lamp may be adjusted by a simple change of connections on the top plate for circuits of from 7,200 to 17,000 alternations, and has a range of adjustment for voltage of from 90 to 130 volts. The outer globe is suspended on a white enameled ring about 7½ inches in diameter, and being directly over the arc acts as a reflector and materially increases the efficiency of the light. One special point in connection with this lamp is that the carbon sheath is removable from the lamp.

In designing these new types of Manhattan lamps, quality has been the chief consideration. Lamps could be built which would give almost the same apparent results at the start, but to secure ease of handling, perfection of operation and durability, there have been introduced materials, methods and styles of finish, which while increasing the cost of the lamp very materially, present a series of structures practically perfect in every detail. There is no reason why the only consideration in the purchase of arc lamps should be price, and it is to be hoped that central station people will appreciate the economy in well constructed lamps, as the slight addition of first cost is not to be compared with the cost of repairs and reliable service. The design of these lamps should certainly maintain the high reputation made by the Manhattan Co.

These lamps are manufactured under patents of the Marks Enclosed Arc Light Co., Moses S. Okun, Max Harris and others.

The Warner Battery Telephone Generator.

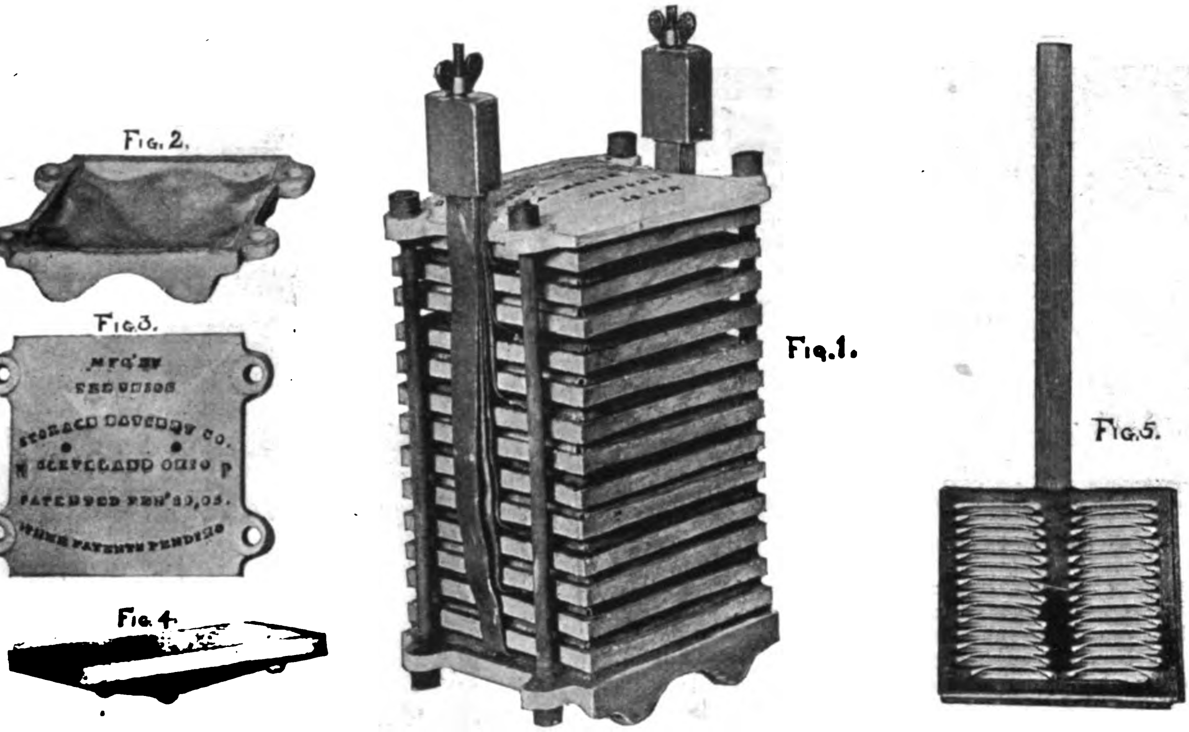


The cut shown herewith illustrates a new telephone generator, which has just been placed on the market by the W. F. Warner Co., of Muncie, Ind. It can be operated with batteries, either primary or storage, and can also be used in connection with electric lighting circuits. The power required to operate this machine is about three-tenths of an ampere at eight volts pressure and it is suitable for exchanges having less than 1,500 subscribers. It is a handsome machine, with marbelized slate base and nickel plated trimmings, has few wearing parts, consequently it is almost indestructible, and would be a valuable addition to country exchanges where electric light circuits are not accessible.

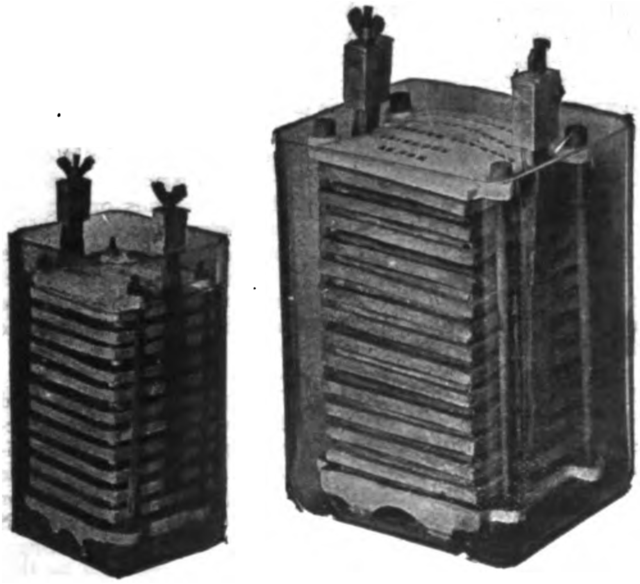
THE UNITED GAS IMPROVEMENT COMPANY, of Philadelphia, are installing at Yonkers, N. Y., a 50 h. p. Ball engine, built by the Ball Engine Company, Erie, Pa.

The Union Storage Battery Co. of Cleveland, O.

We illustrate and describe on this page a new type of storage battery which is being put upon the market by the Union Storage Battery Company, of Cleveland, with which Mr. F. C. Phillips, so well known in connection with the Elwell-Parker Electric Company, is prominently connected. It would seem that a large field of usefulness awaits such a type of cell as this. The battery or element, shown in Fig. 1, consists of a pile or stack of concave porous dishes in which are placed the lead conducting grid and the active material. The connections or conducting strips form alternate grids, constituting the positive terminal or pole of the element, being brought up on one side, and the remaining alternate strips on the other side, constituting the negative pole of the element. The stack of dishes, filled or charged in the above described manner, are held together by means of hard rubber rods between strong bottom and top pieces of glazed earthenware that are separately shown in Figs. 2 and 3. Fig. 4 shows the concave porous dish which carries the active material and the shutter-like grid shown in Fig. 5. The conducting grids are stamped out of pure homogeneous rolled lead. In the larger batteries, the terminals are arranged for suitable lead connections, to be made when the battery is set up in its permanent location. It will be readily seen that, since the active material and the conducting grids are securely held between the dishes, short circuiting is all but impossible. This latter is an exceedingly important and valuable feature of this battery. It will also be obvious that the element can be easily and with safety lifted as a whole out of its containing jar. The active material is placed in the porous dishes in the form of loose, dry powder, and is held or carried by the dish and not by the conducting grid; the conductor or grid resting mainly upon and in the active material. Owing to this fact, and to the fact that the plates are horizontal, the active material always tends to remain in contact with the conducting grids and does not fall away from such contact. This makes the battery, as it were, self-repairing, and besides eliminates any appreciable tendency of the plates to buckle or warp.



FIGS. 1, 2, 3, 4 AND 5.—DETAILS OF THE UNION STORAGE BATTERY.



FIGS. 6 AND 7.—COMPLETE CELLS OF THE UNION STORAGE BATTERY.

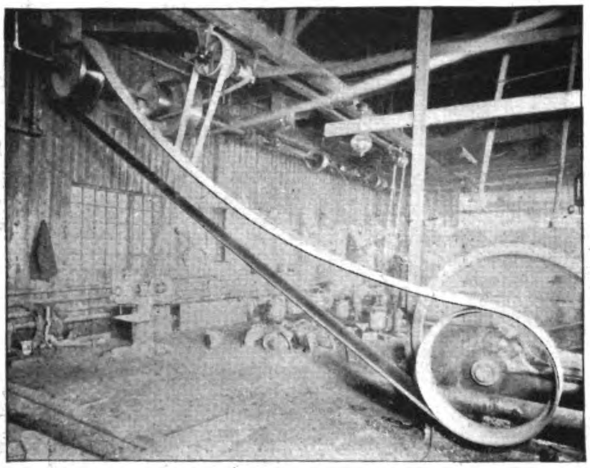
The weight of this battery can be reduced, if necessary, to a minimum for the reason, chiefly, that the lead grids can be made very light since they are of pure homogeneous and dense, rolled lead and perform the function of conducting current only; not supporting or carrying the active material or supporting their own weight. The smallest and the medium size of battery are shown in Figs. 6 and 7. It will be obvious that these cells can readily be connected up together, that they are easy to keep in repair and good condition and that they have a large capacity in proportion to their weight.

Dennison Tags Made by Electricity.

The celebrated "Dennison" tags are now made by Westinghouse electrical apparatus. The plant of the Dennison Mfg. Company, at South Framingham, Mass., represents ideal types of direct current power apparatus, well installed and operating in a manner that is entirely satisfactory to the owners. Electric apparatus of Westinghouse manufacture is used for the entire shops, the only steam plant being that which drives the generators. A complete system of arc and incandescent lighting is also in operation. The generating plant consists of one 200 kilowatt generator running at 100 r. p. m.; one 100 kilowatt generator of the same speed, and one 30 kilowatt machine running at 300 r. p. m. The machines are all of the 125 volt Westinghouse engine type. Seventeen slow speed Westinghouse multipolar motors of from 5 to 50 horse power are used for driving the shop machinery.

The "Cling-Surface" Belt Dressing.

THE illustration below shows the effect of the "Cling-surface" belt dressing on the bearing surface of a long belt in the shops of the Union Dry Dock Company. In the words of the foreman "For one year now, the belt has been treated with 'cling surface,' and although we have let it out, as shown in the illustration, it develops far more power than before, while the strain on bearings and belt is reduced to a minimum." Many favorable comments have been passed on this well known

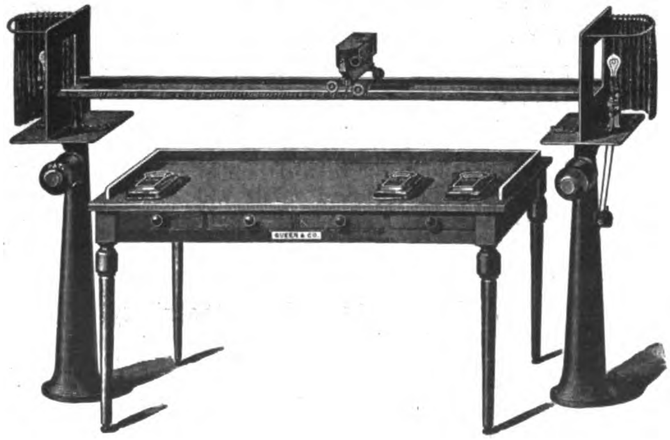


PLANT USING "CLING SURFACE" ON BELTS.

belt dressing in the past few years by prominent manufacturers and engineers, for it has many admirable qualities. It penetrates the leather, canvas or rope and produces a smooth clinging surface. It does not oxidize or evaporate like grease or oil, consequently what goes into the belt remains there. It is sold in 25, 50 and 100 packages or in barrels by the Cling-Surface Mfg. Co., 10 Court street, Buffalo, N. Y.

A New Queen Electric Light Photometer.

THE firm of Queen & Co. have placed on the market a new photometer, illustrated herewith. As will be noticed, it is a departure from the usual design. Cast-iron pedestals support the metal photometer bar and carry stages for the support of the lights, screens, etc. The rheostat shown on the left hand pedestal is for the control of the potential on the standard. It is about 800 or 1,000 steps and permits of perfect adjustment. A similar rheostat on the right regulates the current on the test lamp. The graduated bar is inclined at an angle of 45 degs., in



QUEEN & CO.'S CENTRAL STATION PHOTOMETER.

which position the graduations are lighted by the lamp under test.

The screen, which may be of either the Bunsen or Lummer-Brodhun type, is mounted on a truck and may be rolled along the bar wherever desired. A milled-head permits of close adjustment when balance is nearly attained. The instrument is complete in every respect, and the result of several years' experience with photometric apparatus. Those interested may obtain from the makers a circular more fully describing the photometer.

The Graves Arc Lamp.

THE Graves arc lamp, which is displayed prominently in our advertising pages of this issue on a colored sheet, is worthy of attention. The broad field in which these lamps have been used and thoroughly tested by many hands under the most

GRAVES ARC LAMP.

extreme range of conditions, under the widest climatic changes, and the attendant patient study to practical detail, have brought them where they stand to-day, a standard of excellence in their line, and have forced electrical engineers and experts to recognize them as such. The increased demand for the past seven years is unimpeachable evidence of this fact, and to keep pace with the times Mr. Graves has constantly added more capital and modern machinery, until now his plant is one of the most complete in the country.

The Graves arc lamp received highest honors at the World's Fair in 1893 "for good construction and satisfactory performance when in use," and there have been no pains or expense spared since to keep pace with the improvement of the times.

Their long-burning enclosed arc lamp, which was brought out about three years ago, has met with great favor, and improvements have been made since that time so that it stands at the front, and can be depended upon for satisfactory performance under the most exacting circumstances.

PROVIDENCE, R. I. The Westinghouse Electric and Manufacturing Company has recently completed a novel electric plant for the Fletcher Manufacturing Company, of Providence, R. I. This latter firm is over 100 years old. The original Fletcher manufactured shoe strings and sold them for wheelbarrows. The concern is now one of the most successful in Providence, employing about 600 hands, making shoe strings, lamp wicks, etc. Until recently, two engines were used by this plant, one on each side of the street. Desiring to shut down one of them it was found impossible to run a shaft under the street, but permission was secured to lay electric wires. The single engine will now operate the entire plant, by running a 150 kilowatt, 400 volt, two-phase Westinghouse generator, which transmits current across the street to a 200 horse power type "C" motor. The motor is left connected with the generator most of the time, thus enabling the two plants on the two sides of the street to start up together.

Improved Thompson Focusing Electric Lamps.

FIG. 5.

We illustrate and describe herewith the improved focusing arc lamp which has just been brought out by A. T. Thompson & Co., of Bromfield street, Boston, embodying a number of advances in this important class of apparatus. Fig. 1 shows the open reflector "Olivette" box for lighting large areas such as back drops, side or wing tables, tableaux and all close range work. It is provided with a 90° improved Thompson lamp, either hand feed or automatic, and will run on either the direct or the alternating current. The electrical lens box or chaser is shown in Fig. 2, which is made interchangeable for open reflector as in Fig. 1 or for stereop-

FIG. 1.—OPEN REFLECTORS FOR LIGHTING LARGE AREAS.

ticon attachment as in Fig. 3. The electric lamp is the 90° pattern, entirely enclosed within the lens box to prevent leakage

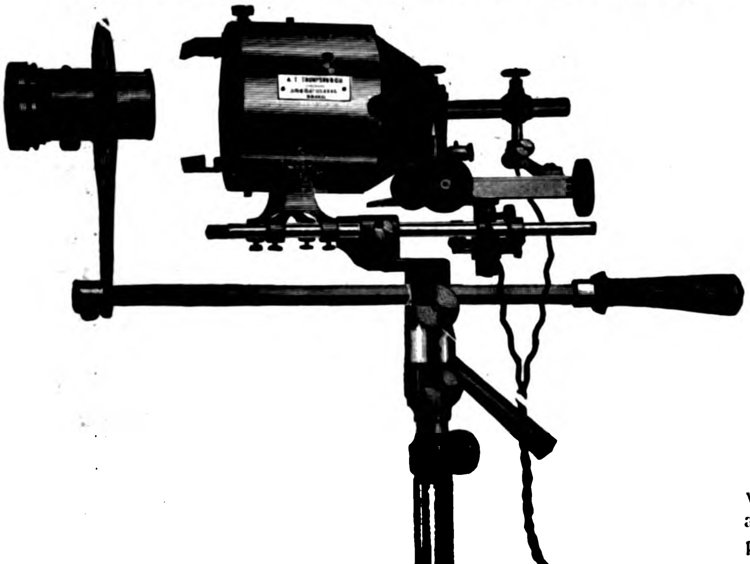


FIG. 3.—SHOWING OPTICAL PROJECTION ATTACHMENT.

of light. The lamp may be focused forward and backward for producing discs of light varying from a "spot light" to an area equal to the entire stage. The condensing lens is mounted specially to allow for expansion and contraction, and the risk of breakage is reduced to a minimum. The entire upper part of the apparatus is hung in a swivel socket, held by a large thumb screw, and may be inclined rapidly at any angle by the

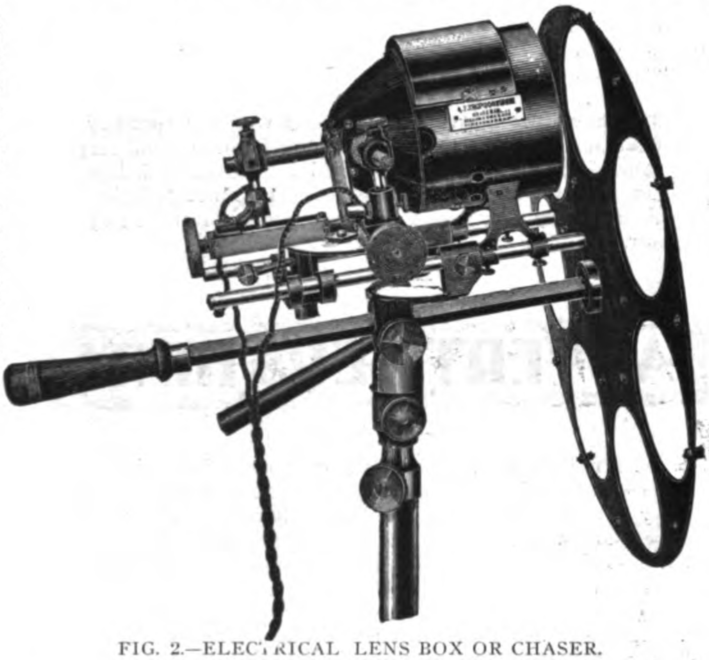

FIG. 2.—ELECTRICAL LENS BOX OR CHASER.

movement of the lever. A large wheel for seven colors is provided, as shown in the illustration, or a small wheel for four colors. The latter may be used to advantage for illuminating the serpentine dance by revolving rapidly.

Fig. 3 shows the optical projection attachment for producing moving water, rainbow, and all other similar effects, either at short range from the stage, or from the balcony; also for illustrating lectures, and in "between the acts" numbers. It may also be used for the exhibition of election returns, news items, etc. This apparatus is similar to the one shown in Fig. 2, to

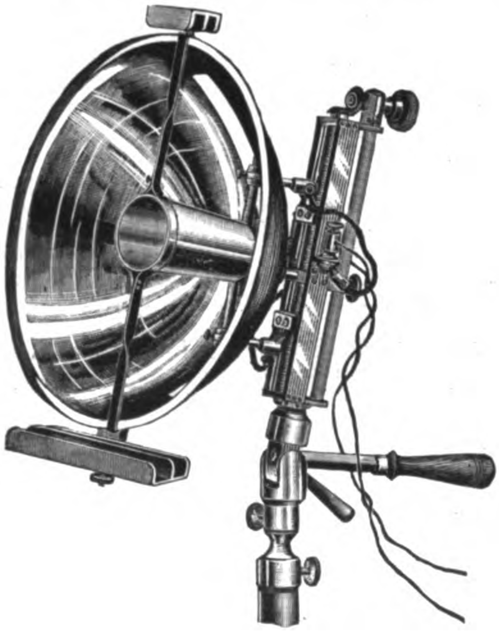

FIG. 4.—IMPROVED BALCONY FRONT LIGHT.

which has been added an extra plano-convex condensing lens and slide carrier (all in one), objective lens and support. These parts may be instantly removed. All parts shown in Figs. 1, 2 and 3 are interchangeable; hence with one piece of apparatus it is possible to produce all stage lighting effects which ordinarily require the use of three pieces of apparatus.

The improved balcony front light is shown in Fig. 4. This

lamp is provided with a corrugated glass reflector, and a collecting tube to prevent the spread of light directly from the arc, making it possible to focus the beam as with a calcium. The candle power may be anything desired from 2,000 to 10,000 and is regulated and controlled by an improved adjustable rheostat. The reflector is provided with grooves for holding colors. The stand adjustments are the same as supplied with the other Thompson stage lamps. This apparatus may be fitted with an automatic electric lamp which is desirable where lamps are to burn for any length of time without color changes.

Fig. 5 shows the horizontal feed lamp which is specially designed for use in connection with electric fountains and serpentine dances, the light being projected from a point below the stage or fountain through plate glass. The reflector being adjustable vertically, the spread of light may be controlled by the operator.

ADVERTISERS' HINTS

C. W. KENNEDY, 44 North Fourth street, Philadelphia, advertises electric vehicles containing the greatest capacity and efficiency with the least weight. In another place in this issue may be found a description of this type of carriage.

TWENTIETH CENTURY LAMP WORKS, 1031 Walnut street, Philadelphia, are introducing an incandescent lamp of very novel construction.

J. JONES & SON, 64 Cortlandt street, New York, advertise ceiling, wall and desk fans for alternating and direct current.

HAMMACHER, SCHLEMMER & CO., 209 Bowery, New York, are at all times prepared to supply tools for many purposes, including drills, reamers, taps, files, saws, wrenches, etc.

THE NOWOTNY ELECTRIC COMPANY, 208-212 Lawrence street, Cincinnati, O., call attention to their 150-hour arc lamp of the enclosed type. Their catalogue is interesting.

GEO. M. MAYER, 79 Fifth avenue, Chicago, Ill., advertises telephone materials of all kinds.

JAMES BONAR & CO., 121 Carnegie building, Pittsburg, the manufacturers of the Pittsburg feed water heaters, purifiers and receivers, mention the enormous sale recently made by them to the Carnegie Steel Company, amounting to 22,500 h. p.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., illustrate their direct coupled ventilating fans and also mention transformers, illuminated dial instruments, ceiling fan motors, single-phase power motors and direct current motors and generators.

THE BRUSH ELECTRIC COMPANY, Cleveland, O., present a revised list of the stations in which large Brush units have taken the place of smaller units. It aggregates 22,000 lights.

THE W. D. GRAVES ELECTRICAL AND MACHINE WORKS, Cleveland, O., refer to the points of merit their lamp embodies and make a guarantee with specific features on all lamps they sell, so positive are they that their claims are correct.

A. L. BOGART COMPANY, 123 Liberty street, offer dynamo electric torches at reduced prices.

THE GARVIN MACHINE COMPANY, New York City, advertise drill presses in a large variety of styles and sizes.

THE OTTO GAS ENGINE WORKS, INC., of Philadelphia, have removed their Chicago office to 360 Dearborn street.

THE WOLVERTON-ELLIOTT ELECTRIC COMPANY, 442 Niagara street, Buffalo, N. Y., are always ready to undertake general electrical repairs. They have been in this particular line of business seventeen years, and there ought not to be much they do not understand.

THE ELECTRIC GAS LIGHTING COMPANY, 192 Devonshire street, Boston, Mass., advertise the No. 2 Samson battery "shipped set up."

THE W. F. WARNER COMPANY, Muncie, Ind., are bringing out a device for generating current for telephones. It is operated by storage batteries, primary batteries or any source of electric current. They will be pleased to furnish details.

THE CROFTON STORAGE BATTERY COMPANY, 327 Dearborn street, Chicago, request an opportunity to quote low prices on their batteries. Some of the characteristics are noted.

WESTERN NOTES

THE CENTRAL ELECTRIC COMPANY, Chicago, report a brisk trade in Westinghouse alternating current fan motors, one reason for this being the fact that they are carrying large quantities in Chicago stock. Hot orders in hot weather can be filled immediately.

CHAS. S. WEISSE & CO., Sheboygan Falls, Wis., are installing an electric plant for power and lighting purposes in their works at that place. A 110 h. p. Ball engine, built by the Ball Engine Company, Erie, Pa., will furnish the necessary power. An electric light and power plant is being installed in the works of the Jackson Corset Company, Jackson, Mich. A 60 h. p. Ball engine, built by the Ball Engine Company, will furnish the power.

The Electrical Engineer.

Vol. XXV. JUNE 23, 1898. No. 529.

Westinghouse Crane and Elevator Motors.

THE Westinghouse Electric and Manufacturing Company has made a special feature of motors for crane and elevator service. The advantages to be gained by the use of electrical machinery in this field can scarcely be overestimated. While the great economy of electrical methods is strongly in their favor, often, for the sake of cleanliness, ease of operation, and adaptability to various kinds of service, the electric system is adopted when economy is quite a secondary factor.

The saving in a power crane over one operated by hand is undisputed. It is gradually being conceded that the electric crane is as far in advance of the steam crane as the latter was superior to the old hand type. Large saving in cost of operation has been reported from many quarters since the introduction of electric power. In one instance this was so great that an investment of several thousand dollars in two large electrically operated cranes paid for itself in eighteen months from the time of installation. Messrs. Wm. Sellers & Co. report another case where the saving in labor by introducing a ten-ton traveling crane, electrically driven, amounted to upward of $100 per day.

The above firm, in its catalogue on cranes, makes the following statement: "The electric motor furnishes the most convenient means yet devised of communicating power from a stationary source to the operating mechanism of a traveling crane."

The Case Mfg. Co., in its handbook on hoisting appliances, says: "It is no exaggeration to say that during the past ten years the development and subsequent introduction of electrical machinery in connection with almost every line of manufacturing industry has done more to reduce the cost of production than any other agency."

In no line has this been more conspicuous than in the operation of machinery for handling the product of our large mills, factories and railway shops. Prominent among such machinery stands the three-motor overhead traveling crane. Without its efficiency the mammoth proportions of our iron and steel foundries and kindred plants would be impossible. So generally is this recognized that a foundry not provided with overhead traveling cranes electrically equipped is now regarded as antiquated, even if built within the past four years. Everything in the way of improvements in this valuable device can not fail to be of interest to all those requiring such machinery.

The location of the motors is left to the builders of the crane. In most cases the bridge propelling motor is located on the side of the bridge directly over the observer's stand. This is most favorable to the operator. For foundries, this situation is especially favorable, as it exposes the motor to the least heat from the foundry floor and it is in most cases so arranged that when thus placed the motor in whole or in part can be removed without displacing any other part of the machinery. Each motor is especially prepared for crane service. Ample margin should be allowed for capacity.

The principal objections to the use of motors for this purpose in the past have been on account of mechanical difficulties with regard to speed, starting, and the harmful effects of dust and dirt. These difficulties have been met and overcome by both the Westinghouse alternating and direct current motors, which have been in successful operation under the most exacting service for the past three years. These motors were the first practical machines of their kind. The direct current dust proof motor is designed on the same lines as the Westinghouse multipolar generators and motors. It is planned especially for crane and elevator service, and every detail has been worked out with that end in view.

The dust proof motor has the same type of armature and poles as the ordinary multipolar machines, but has a circular frame and end plates, thus completely enclosing and protecting the mechanism. The plates are fastened by four bolts. A view of the motor and parts is shown in Fig. 1. The motor is light in weight and compact and simple in construction, without having undergone any sacrifice in durability or strength. It is absolutely dust proof.

One of these machines was supplied by the Westinghouse Company for the U. S. S. "Indiana." It is used for the ammunition hoist on the vessel, and has fully met the severe requirements imposed upon it. This motor was of course required to be entirely spark proof and dust proof. It runs in either direction without changing the position of the brushes.

The Westinghouse alternating current motor has proved its utiltiy in many striking applications. In no field has it been more successful than in that of crane and elevator service. Many large plants are equipped entirely with this system of distribution, and the compactness and efficiency of the apparatus has in every case been manifest. A prominent example of this is to be found in the new shops of the Boston & Maine R. R., at Concord. The two-phase alternating system is here used. The electric crane circuits are wired for a current of 200 amperes. The transfer table requires 60 amperes. All circuits are at a potential of 440 volts, excepting those supplying the lamps at the shops and at the Y. M. C. A. Building, half a mile from the shops, which are 104 volt.

The motors are of the Tesla polyphase induction type, built by the Westinghouse Company, running on 7,200 alternations. The uses to which the motors are put are as follows: To run shafting for the locomotive shop, for the bending rolls in the boiler shop, for driving the fans in the forge room, and other blacksmithing machinery, and in connection with the cranes and transfer tables.

The Westinghouse alternating current motor is especially adapted to this kind of work, and the type used in this installation is worthy of study. The motor consists essentially of two elements, viz., a stationary part permanently connected to the main circuits, and a rotating part having no connection with any other portion, and absolutely no contacts or adjustments. There is no sliding or working friction except that of the shaft in the journals. These are the only parts that are subject to wear. On account of the light weight of the rotating part, this friction is very slight. Ample self-oiling bearings provide for liberal lubrication. The motor is designed to operate with maximum effectiveness and minimum attention.

The hollow cylindrical frame of cast-iron, in which the primary is mounted, forms a base for the machine and also supports the two end brackets carrying the self-oiling bearings. Perforated iron plates fitted into these brackets protect the rotating element and permit excellent ventilation. They may be replaced by solid plates when it is desired to make these motors absolutely dust proof. It will be noted that the housing completely encloses the primary and secondary elements and protects them from damage.

The primary element consists of a hollow cylinder built up of sheet iron rings laminated and slotted on the inside to receive the conductors. These rings are rigidly supported by the cast-iron housing which encloses the primary. The conductors are machine wound coils which are thoroughly insulated before being placed on the core. The terminal blocks which are located at the top of the machine are connected to the primary winding by leads which pass through the housing.

The design and principles governing the construction of this motor (known as the Westinghouse Type C) are favorable to maintaining a high and almost constant efficiency from full load to one-half load. By maintaining a constant efficiency, it is possible to secure an all day or average efficiency very much above that heretofore obtainable, with either direct or alternating current motors. The variation in speed between no load and full load is small, being less than that found in direct current motor practice, as determined by exhaustive tests.

A polyphase induction motor may be started by connecting it directly to the circuit by means of an ordinary switch. Small motors are so started in practice. The larger motors are started on a reduced voltage, the full e. m. f. of the circuit not being applied until the motors have reached a considerable speed. The fact that in a four-wire two-phase circuit different e. m. fs. exist between different pairs of wires, affords an easy way of obtaining

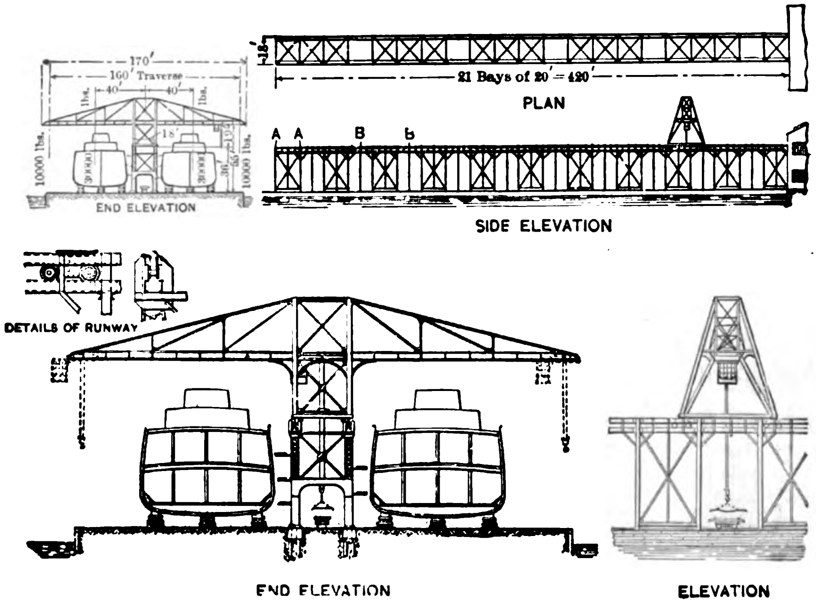

FIG. 5.—DETAILS OF CRANE CONSTRUCTION.

the necessary reduction in voltage. For some classes of two-phase and for three-phase service the reduction of voltage is effected by a device called an auto-converter. This device is entirely separate from the motor itself. It is possible, by the use of the auto-starting device, to adjust a motor after installation to have any desired starting torque within very wide limits. Thus a motor operating machinery having great inertia may be made to give a correspondingly strong starting torque, while one driving a very light device may be adjusted for extremely small starting torque, with a corresponding reduction in starting current.

The crane motors are provided with a regulator, by which the pressure is varied. The motor receives from the regulator a pressure varying from a small amount up to the maximum for which the motor is adapted. This variation gives a starting torque which is about four times the torque which the motor can develop at high speed continuously. The motor has a maximum speed which it does not exceed, even though the full pressure be applied with no load. The regulator consists of a special form of transformer, by which the voltage is efficiently reduced. A number of terminals are brought out from the transformers which are carried to the regulator so that the pressure from the various contacts can be successfully applied. The crane motors are exactly similar in constructi n, operation and simplicity, to the constant speed motors.

Another example of heavy work with crane machinery is at the works of the Westinghouse Machine Company, East Pittsburg, Pa. A forty-tone crane is here operated by two 20 horse power motors (alternating current) for the main hoist, one 10 horse power for the auxiliary hoist, two 5 horse power for the trolley travel, and one 20 horse power for the bridge travel.

Fig. 2 represents the main aisle at the Pittsburg works of the Westinghouse Electric and Manufacturing Co. This immense area, 750 feet long and 70 feet wide, is spanned by three 30-ton cranes, operated by 140 horse power of electric motors, each crane being manipulated by one man.

Fig. 3 shows a Westinghouse electric crane in operation. Fig. 4 shows a pair of alternating current motors on an electric crane ready for shipment. The details of construction in a crane service of this kind are shown in Fig. 5.

The motors are easily connected to types of cranes now standard, and offer the cheapest, safest and cleanest method of operation. The question is no longer, "What can be done?" The intending user has but to ask, "What has been done?" to learn of the enormous extension of the applications of electric power.

MUNICIPAL AFFAIRS

Public Lighting in Relation to Public Ownership and Operation.[1]

BY ALEX. DOW.

THIS paper is written to set before the association a proposed policy. It is not a new policy in its parts, neither is it an untried policy. It is applicable immediately to public lighting; that is to say, to the lighting of streets and public places under contract with, or on account of a municipality. Ultimately its application may be more extensive.

It is the belief of many members that the National Electric Light Association should formulate and publish a well-considered method of dealing with this business. While local conditions differ, there is no local difference in the principles which should govern electric lighting companies in their dealings with municipalities and municipalities in their dealings with electric lighting companies. An authoritative statement of these principles is needed. A statement by the association may be accepted in the first place only by the electric lighting companies, but if the principles so stated are intrinsically correct, their acceptance by the municipalities must follow. No city government will persist in a course that is plainly inequitable. City governments have in certain cases acted inequitably in the matter of public lighting, but their action has not been plainly inequitable. In such cases principles have been obscured by details or by personalities or have been but distinctly understood by the parties on both sides of the case. The public does not seek to be served at the expense of the individual. Public opinion may at times be biased, but it intends and endeavors to be just. And under our scheme of government public opinion is the final authority; and an appeal to public opinion is the ultimate means of redress for any grievance.

The advocates of municipal ownership have long recognized the value of public opinion and have presented their case both to the people of the country at large and to the citizens of selected municipalities through magazine articles, newspaper discussions, and addresses to public gatherings. Some of our members have met these arguments in kind and have confuted extravagant statements by the presentation of facts. But the man who is plainly arguing in his own interest is handicapped in a debate before a non-judicial tribunal as against those who claim to be disinterested. And it is not to be denied that the arguments which have had most influence on public opinion in this matter are those of theorists who certainly believe that they are doing the world a service, who are usually misinformed, always impracticable, but thoroughly in earnest.

A declaration of principles by this association and the recommendation to its members of a policy based on those principles would have greater weight with the public than the statements of individual companies, and would be accepted as authoritative over a wider area. But even if not accepted by the public its immediate acceptance by our own members will be useful. That each member must act for himself is a consequence of the conditions of our business, but that all should act on similar lines is possible and is desirable. Each of us looks to other cities than his own for light on problems which are new to him. Each of us, by a successful solution of any problems, benefits the industry at large, and, on the other hand, he who fails to appreciate and to properly deal with such a problem as this, injures, by his failure, not only himself, but all of us. Therefore it is well that we should agree on general principles and that we should advise with one another on special cases.

Let me make this general statement more specific. The member of this association who, by good service, by close figuring of expenses and of profits, and by clear statements and logical arguments, convinces the authorities of his own city that it is to their interest to leave their public lighting in his care, has done all of us a service. The member who, on the other hand, fails to recognize the drift of opinion among his fellow citizens, who tries to convince them that unsteady and uncertain lights are worth a high price, who depends for the retention of his city lighting contract on an appeal to the technicalities of his State law, or to the pockets of the venal members of his local Board of Aldermen, and who thereby brings about the erection of a municipally-owned electric lighting plant and the publication of the bare running costs of that plant in parallel columns to the prices which he wished to charge—the member who does these things which he ought not to do, and leaves undone those other things which he ought to have done, is a detriment to the industry throughout the entire Union.

I have indicated why I believe a declaration of principles and of policy is desirable. The principles to be declared will need little discussion, but the policy which to me appears best, may, when examined by others, appear to require amendment, or even radical change. It is offered to you for consideration in the belief that it is logical and that it is practical; but as a proposition for discussion and amendment, rather than as a perfected plan.

A CHAPTER OF ELECTRIC LIGHT HISTORY.

In the history of street lighting by electricity no chapter contains more profitable matter for study or for illustration of general principles than that which contains the record of the city of Detroit. That city was one of the first to use electric lights on its streets. It began in 1883 with 22 arcs, and in 1884 abandoned all other street lights. This street lighting business was believed by those who first engaged in it to be a monopoly secured by patent rights; they found their mistake after much money had been invested under that belief; competition ensued; then consolidation, and finally municipalization of the service. I shall find it convenient to refer to Detroit for more than one modern instance.

In February, 1896, the city of Detroit owned 1,500 arc lamps and was operating 1,492 of these in the work of street lighting. In the same month the successor of the Brush Electric Light

[1] Read before the Nat. Elec. Light Ass'n, Chicago, June, 1898.

Company, which installed the original 22 lamps in 1883, and which, until 1890, lighted the streets under contract, owned 1,049 arc lamps, and used in private lighting 433 of that number. Another company, organized in 1890 to compete with the Brush Electric Light Company, owned 1,330 arc lamps and was using in private lighting 38 of these. In each case there accompanied the arc lamps a sufficient number of dynamos, engines, boilers, etc., and a building fully equipped for the operation of the number of lamps stated. At the same time the city had in use 134 towers, which has been formerly owned by the Brush company, and the other company was in the act of taking down and removing from the streets 104 similar towers, which had formed a duplicate of the Brush company's equipment. The necessary lines to connect lamps distributed over a large city had been owned by all three. The city had in use 329 miles of overhead wires, connecting to its 1,492 lamps. Neither of the companies had owned such a great mileage of line, but one had taken down lines and poles which had supplied 719 lamps, and the other was in the act of removing lines and poles which had connected in 1,279 lamps.

Some of the Brush company's street lighting equipment had been during the preceding five years diverted to the supply of commercial lights. Nevertheless, two-thirds of that equipment is to the present day a useless asset. Lamps which were bought at $40 have proved impossible of sale at one-tenth of the price. Dynamos which cost $2,400 cannot be sold to-day for $240. Lines taken down returned only a small percentage of their cost to the treasury. The towers which this company sold to the city did not bring their original price—that goes without saying—but they brought a fair price.

The loss of the second company was greater. Changes in the business had made their street lighting arc lamps unavailable for commercial use, or almost entirely so. Similar changes had made their dynamos a slow asset. The engines were partially diverted into commercial service and the boilers entirely so. The wire taken down was not of a size that would fit in to their commercial lighting system and the poles hardly paid for the labor required for their removal. The 104 towers—one of the heaviest of all the original expenses—had to be sold as scrap iron.

A DESTRUCTION OF VALUES.

It is clear that a loss to some person or persons was involved in conditions which reduced machinery and lines capable of supplying over 2,000 arc lamps to approximately their junk value. Leaving out all questions as to personal fault—neither affirming nor denying that the loss fell upon those for whose economic blunders it was the inevitable punishment—it is certain that there was a loss to the community at large; that property which might have been and which had been capable of doing good service to the public, was as surely destroyed as if it had been swept out of existence in a great fire.

It may be asked on whom did the loss fall? In social economy the loss of one is the loss of all, but to our customary modes of thought there appears a difference between losses borne by ourselves immediately and those which are apparently borne by other people. In this case the greater part of the loss was borne by business men of the city of Detroit. It was a reduction of the available capital of men engaged in productive industry in the city. This reduction—this absolute loss—after correcting for inflated values which should have been written off long before the period of liquidation; after correcting for securities issued for cash at less than their face value, or for considerations which were valued at more than their true worth, was not much less than $400,000.

I do not ask you to sympathize with the immediate losers, but I ask you to remember as my argument proceeds that this loss came about in consequence of business methods and of social tendencies which are in active operation to-day in nearly every town represented in this association. And I submit as a principle not admitting of dispute, that the duplication of an effective equipment for public lighting is an economic error, entailing loss of available capital to the extent of the duplication.

IMPROPER COMPETITION.

The first error in Detroit was the offer of the city of competition for the public lighting contract. The men who made the offer knew perfectly that their success would mean a heavy loss to the original contractors, but they were willing to make a profit through other people's losses. In this they disregarded a principle much older than the electric lighting business—that which calls on us to do to others as we would that others should do to us. Some of these men doubtless thought that they were doing the city a service by providing competition, but the managers of the manufacturing concern which was the majority stockholder and chief promoter in the new organization had no such excuse. Their object was to sell machinery. I do not ask you to condemn these people now. They have reaped as they sowed, and the exploitation of competing lighting companies by manufacturing concerns is a thing of the past, although its consequences in the shape of inflated capital are likely to be a burden for years to come.

I submit as a direct application of the principle last stated, that competition for public lighting contracts, for the execution of which there is already an effective equipment in existence, is not legitimate business. The corollary of this statement is that the price at which public lighting is to be performed must be determined by some acceptable means other than competitive bidding. In this there is a departure from the established method of municipalities, which now depend on competition for the setting of prices on all public services performed by contract.

WANTED: A SUBSTITUTE FOR COMPETITION.

In the absence of some other acceptable means of setting a proper price for public lighting by contract, public opinion will not tolerate the suppression of competition. A reference to Detroit illustrates this very well. When the second company had, by making a lower price and by meeting the demand of the public for the undergrounding of wires in the business district, secured a three-year contract for public lighting, its managers found themselves in a precarious position. It was apparent that at the term of the contract they would again have to reduce prices to meet the competition of the original contractor, who could not afford to have his plant standing idle. It was also immediately apparent that the idle plant would be, as far as possible, diverted into private lighting work and would there also tend to reduce prices and to divide the available business. Legal questions as to patent rights added to the difficulty of the situation. An attempt to combine the two interests was plainly necessary, and it was made; but the inevitable personal soreness prevented a combination until the new company had completely duplicated the equipment of the old one.

Of course, the public became advised of the cessation of competition, and the advocates of municipal ownership made the most of the facts and added much fiction. Long before the contract had expired it was plain to any careful observer that it could not be renewed at anything like the former figure, and that the tendency of public opinion was strongly to municipal ownership. It was a period of "reform"—I use the word in its political sense—one of those periods when the taxpayers, usually content to be bossed unquestioningly by the practical politicians, insist on calling the particular bosses of the hour to an accounting and expect to find that they are rascals. And as the public's way of having an accounting is to discharge its servant first and take up the reckoning afterward, the public servants of such periods are quick to fall in with the drift of public opinion in order to show that they either do not deserve discharge or are fully justifying their appointment to their new situations. Politicians are wise at such times; lighting companies sometimes are very foolish.

So the cry went up that there was no such thing as competition in the lighting business; that the men engaged in that business all intended to rob the public, and that if they appeared at times to compete with one another, it was only a temporary falling out among rogues. And the public being told on the one hand that all existing lighting companies were composed of rascals, and on the other that all municipally owned plants were successes, made up its mind that its only salvation lay in municipal ownership.

You can see, and any careful student can see, that the suppression of competition was inevitable, because its continuation meant a cumulative loss to those engaged in it. Possibly the public might have been made to see this, although the time to have begun work on the public was before the first loss due to competition had been incurred. But to merely prove that competition was impossible would not have been enough. It must further be proved that competition was unnecessary, and the only way to do that was to offer good service at an acceptable price. Under the circumstances the price might have to be very low indeed, for the belief was abroad that the business was

enormously profitable at the established rates. The figures sent forth by certain municipal plants were quoted as warranting this belief, but these could have been contradicted. It was possible to send to Bay City and to Topeka a competent engineer—say one of the professors of the University of Michigan—whose dictum would be accepted by the newspapers and their readers; and so to obtain the true figures. It was possible to answer in a similar manner the argument based on the competing bid at the last letting of the contract. That argument was that any business which justified the erection of a complete manufacturing plant on the security of a three-year contract must be exceedingly profitable. The contract price was a good one, but it would not pay for the plant in three years, as the public of Detroit thought it would. A showing of the whole truth as to costs, certified by a recognized authority, and followed by a bid carrying a minimum profit, might have been accepted by the public as a substitute for competition.

A COLLISION WITH PUBLIC OPINION.

And here was made the second great error of the electric light companies. Their managers seem to have been the only people who did not see what was coming. They failed to keep in touch with their public. The public was absorbing all the fool figures that the wildest theorists could furnish, but never a figure deserving credence was offered in contradiction. The public was damning the poor quality of the lights then furnished and was told that it did not know a good light when it saw it. The public was determined to have much cheaper lighting, yet when bids were asked for they were almost as far above a possible figure as the costs published by the theorists were below it. The only hope for the contractors was to secure the support of the more conservative elements by offering good light at a minimum rate. On the failure to do this, and do it quickly and gracefully, municipal ownership was as certain as the coming of summer.

Some effort was made by the companies in the Legislature of the State and in the City Council to protect their interests, but these bodies, especially in a reform year, cannot be expected to go counter to a strong public sentiment. In this they are wise in their generation.

Would the public of Detroit, after the agitation for municipal ownership had become general, have approved of award of a contract at a low price, or would it have insisted on municipal ownership as a matter of principle?

An answer to this is merely an expression of opinion, but I believe that had a low price been offered the agitation for municipal ownership would have been suspended and that the companies might have secured terms more to their interest than was the action actually taken. There were many people in Detroit who did not wish to see the experiment of municipal ownership tried, except as a last resort. There were a few people who believed in municipal ownership as a matter of principle. There were doubtless also a few who expected to reap a personal benefit from the establishment of the city plant. Nevertheless the great majority of the citizens sought only to reduce the expense and to improve the quality of the public lighting, and cared nothing for city ownership, except as a means of reaching a desired end.

In other lake cities where the agitation was fully as strong, concessions on the part of the lighting company led to a continuation of the contract system. The case of Toronto is a notable one, because the municipal sentiment is exceptionally well developed there. The local company is now performing lighting for the city at a figure a trifle less than was estimated as the cost of operation of a city plant. At Cleveland the local company holds the business because it made a price so near to actual cost that there could be no possible saving in municipal ownership, and the price was accepted after a careful inquiry into costs in neighboring cities on behalf of the municipality. The recent case of Tonawanda is another instance of success won on the same lines. There the local company submitted figures made by a recognized authority, showing the actual costs of operation in several representative municipal plants, and followed these figures by a bid more favorable to the city than municipal operation. I am assured that in each of these cities, while the contract figures are low, the management of the local company considers the business ultimately, if not directly, profitable.

THE REASON FOR PUBLIC LIGHTING BY CONTRACT.

In these instances the local companies have retained their public lighting business by demonstrating that it was to the interest of the municipality to let them retain it. In this they have put into successful practice the most important part of the policy which I advocate. I submit that the only sufficient reason why a municipality should contract with a private company for public lighting is that the private company can do the work, and is willing to do it, cheaper than the municipality can itself do it by the direct operation of a public lighting plant. It is in order to show how this comes about.

A DIFFERENCE BETWEEN PUBLIC LIGHTING AND PRIVATE LIGHTING.

There is no longer any question of the right of a municipality to own and operate its own public lighting plant. Electric street lighting is a distinctly public service, which must be provided for by the municipality. It is a service to every citizen; is a sequence of the social conditions which constitute city life as distinguished from rural life, and can only be effectively performed on municipal account and under municipal control. Herein it differs from the electric lighting of private premises, and it is necessary to note the difference. Electric lighting is the cheapest as well as the best light for streets and public places. For private premises, on the contrary, electric light is not a cheap light under usual conditions. It is not now, and is not likely to become, an illuminant of universal use, to the exclusion of gas and oil. Why this is necessarily so is well known to the members of the Association. To the general public it is a statement better proven by a couple of good examples than by a long statement of causes. In the city of Detroit there were, in 1897, according to the annual report of the Water Board, 52,219 supply connections to the city water mains and the "families" in the city were 54,945. Each "family" was certainly a user of artificial light of some kind. Illuminating gas of 18 candle power quality is sold in the city of Detroit at $1 per 1,000 cubic feet. The maximum price charged by the electric lighting companies for incandescent lighting is 14.4 cents per k. w. hour, including renewals of incandescent lamps; the minimum is 4 cents, and the system of charging makes the average price 10.8 cents per k. w. hour, which, allowing for difference in candle power, is equivalent to gas at $1.21½ per 1,000 cubic feet on the average, or to gas at $1.62 to the customer whose individual load factor obliges him to pay the maximum price. These are comparatively low prices, both for gas and electricity. Under these circumstances there are in the city of Detroit approximately 18,000 (?) customers for illuminating gas, and 4,000 customers for incandescent electric light. What light do the remaining three-fifths of the possible customers use? It is safe to say that they use kerosene oil. It is also safe to say that there are very few cases where oil is used merely because gas or electricity is not available. The main cause of the use of oil is its lower cost. I need not say to this audience, although I have found it necessary to make the statement to other audiences which were entitled to be considered intelligent, that there is not the least likelihood of the production costs of kerosene oil, of gas and of electric light materially changing their ratios to one another. As to their selling prices, I think that the Standard Oil Company is better satisfied with the profit which it makes on the sale of kerosene in Detroit, than are either the Detroit Gas Company or the electric light companies in that city with their profits.

I submit, however, a second example of the relative cheapness of gas and electricity, from which example the question of profit is eliminated. The city of Glasgow, Scotland, owns and operates its gas works and owns and operates its electric lighting plant. Neither of them is intended to make a profit. I have in my possession signed communications from the managers of each department in which it is written that the price of gas is two shillings and two pence per 1,000 cubic feet, and that the price of electricity for incandescent lighting (not including renewals of incandescent lamps) is six pence per k. w. hour for the first hour's use of the demand, according to a Wright meter. and 2½ pence per k. w. hour thereafter. Making the same corrections as in the Detroit calculation and assuming that the incandescent lamps paid for as "extras" in Glasgow, are as efficient as those furnished free by the Edison Illuminating Company, of Detroit, the Glasgow price for gas is 52 cents per 1,000, and the Glasgow price for incandescent lighting is equivalent to gas at $1.35 at the maximum rate, and 56¼ cents at the minimum rate. The average is about the same as the Detroit average. I think this example from a city where municipal own-

ership has been most thoroughly exploited, and where the municipal management is above suspicion of inefficiency or corruption, proves beyond question that electric lighting for private use is a luxury, and as such must continue to be used only by those who can afford luxuries; that is to say, by a minority of the citizens of any municipality; not by a majority, much less by every citizen.

Therefore, while it is admitted that the lighting of the streets is truly a public service, which may be performed by the municipality for and on behalf of every citizen, the furnishing of electric light to private consumers is not a public service, but is essentially a service to a few individuals, and as such should not be undertaken by a municipality whose object is to perform only those duties which municipal society as a whole owes to itself as a whole. This principle should be clearly understood, and should be boldly maintained. It is necessary that a municipality shall undertake certain services, and it is possible that it may undertake others, but the propriety of its undertaking any service depends on whether that service is to the public or to individuals; to the many or only to the favored few.

THE POSSIBILITY OF LOW CONTRACT PRICES.

This leaves to private enterprise the supply of electric light to private consumers. In performing this service there will be built and equipped a power house; there will be organized an operating and a managing force; there will be constructed lines of distribution. All of these may be, and part of them certainly will be, adapted to the performance of public lighting, in addition to the service of private consumers. To whatever extent this double adaptability exists in the private plant, there will be duplication of equipment in any other plant separately established for performance of the public work. Moreover it is peculiarly characteristic of public lighting operated all night that its addition to the ordinary work of a private lighting plant tends to reduce the average cost of the combined output. In these considerations rests the possibility of a contractor profitably performing public lighting for a city at or below the price at which the city can itself do the work, and yet it being to the interest of the contractor to undertake the business.

Let us for a minute assume that municipal engineering and management and municipal financiering can be just as good as private engineering and private financiering. If they are not so, it is the fault of the municipality, because technical and financial skill and executive ability are for sale in the labor market and are purchasable by a municipality, even as they are by private employers. There remains only one evident cause which should tend to make the costs of a municipal plant differ from that owned by an individual or a company. That difference is that the individual proposes to make a profit and the municipality does not. Looking closer at the facts we find that the municipality must in most cases allow the equivalent to a profit, because a municipal plant is built by money borrowed at interest. In the case where the money is not borrowed, but raised by direct assessment, the municipality has prevented some of its citizens from profitably using the money taken from them by taxation to be invested in the lighting plant, so that even in the exceptional case the possible profit to the taxpayer on the money withdrawn from his business has to be considered. But the rate of interest on municipal bonds is usually less than the rate to profit which a private owner is willing to accept on money invested in the electric lighting business. It is four per cent. as against six or seven or eight per cent. In the final analysis the difference between the cost of lighting by contract and that of lighting at cost by a municipally owned plant should not exceed four per cent. on the capital invested in the plant. I assume in making this statement that the rate of interest on city bonds is a fair measure of the profit that investors expect on a secure investment. If the investment in an electric lighting plant were equally secure, the rate of interest necessary would be no greater. The security depends so largely on the policy of the municipal authorities that it may approximate to that of municipal bonds on the one hand; or, on the other, it may be of the same order as the stock of a speculative gold mine or a Klondike expedition. In saying that the difference should not exceed four per cent., I am to be understood as implying such conditions as take the investment out of the speculative class. I am also to be understood as implying that proper salaries for management have already been paid out of earnings, and that the profit mentioned is that payable to capital alone; in other words, an exact parallel to the payment of interest on a municipal bond.

THE ADVANTAGE OF THE CONTRACTOR.

It follows that if the organization and equipment of an existing plant engaged in the supply of electric light to private consumers is available for the purpose of performing public lighting, this maximum difference of four per cent. can be thereby reduced or even reversed. In every case the difference should be reversible. There are causes to be considered later which tend to the contrary, but the fact remains that there is no irremovable cause why an existing electric lighting plant should not be able to perform public lighting at a less price than the municipality can do the work itself.

THE DISADVANTAGE OF THE CONTRACTOR.

Of the causes which tend to the contrary, one is that the plant which has a contract for public lighting may have very little private service, or none at all. Some other plant in the same city may do all or most of the private business. This condition of affairs can be only temporary. The consolidation of the two plants is an economic necessity, certain to arrive in time. The only condition justifying the existence of two plants in the same city is that the city is so large as to make a division of territory desirable; and even in that case an operating agreement is to be preferred to complete independence.

The public has been told that consolidation of plants is not to the public interest. This is an error, and the way to prove it such is to give to the public the surplus profits of consolidation in the shape of lower rates and better service—either or both.

Another cause tending to handicap the contractor is that few municipalities will make contract for a long term of service. Even the advocates of municipal ownership who are willing to issue twenty or thirty year electric light bonds, and who will not write off more than three or four per cent. for depreciation of plant in making their estimates of city operation, will protest against a contract running more than a year or two. They claim for the municipal plant all the advantage of a secure investment, and simultaneously deny these advantages to the contractor. We know that the securing of a long-term contract permits the installation of the most economically operated machinery, and reduces the percentages of profit, which must be earned annually. The objection to the long contract, that it denies to the city any share in the profits of possible improvements effected during the term of the contract, can be met by so drawing the contract that the margin of profit shall plainly be reasonable to begin with, and that the city may share in the results of improvements in consideration of guaranteeing a similar reasonable profit on the investment to be made in such improvements. A ten or twenty year contract with such a clause could be safely taken at a very low price.

A possible solution of this problem is city ownership of the plant, combined with operation by a contractor. I think that this plan may by and by become common. It involves too many details to permit of my discussing it at present.

CAPITAL ACCOUNT.

The very worst handicap that a contractor may have to carry is excessive capitalization. Here it must be noted that many municipally owned lighting plants do not report all their capital expenditure, so that in carelessly made comparisons of fixed charges the contractor appears to have overstated his investment in order to increase the apparent cost of operation. Any comparison must be on an identical basis for capital as well as for operating charges. And for the purpose of adjusting prices between municipality and contractor, only one basis for capital charge is acceptable; namely, the present value of the plant in brief, a properly made inventory. This proposition is so radical that I state the reasons for it.

The possible bases for a capital charge are as follows: First—The face value of the securities issued by the plant. That this is an impossible base of adjustment is too well known to all electric light men. Second—The current market value of these securities. This is impracticable, because many securities are not on the market, and because the immediate earning capacity of a plant affects the price of its securities, and because—last, but not least—some securities are speculative rather than industrial. Third—The actual cost of the plant. This would be proper if all plants had been built at the same time and if no plant had been obliged to be rebuilt. As it is, the construction cost of two plants built, the one in 1888 and the other in 1898, the two of

identical capacity and of similar type, may be to one another as two to one; the earlier plant may have cost twice what was paid for the later, solely because of the reductions in the prices of machinery and material of construction in the last ten years.

The only remaining possible base for a capital charge is the present value of the plant; and I do not think that any other can be made acceptable for the specific purpose of adjusting a price for public lighting. It does not follow that the capital account is to be readjusted to a corresponding figure. It is only requisite that the company accept as a proper profit on public lighting business an allowance based on inventory value of the investment. It would be well for the industry, however, if all our capitalizations were brought near to present values. And one good result of revaluation would be a logical sequence—the depreciation of the investment from year to year would necessarily be admitted as a proper charge against revenue. If a profit is only to be allowed on capital sufficient to construct a plant at the comparatively low construction prices now ruling, any further decline in cost of construction must be considered an impairment of capital, to be made good before any profit can be paid. It is not to be understood that I expect an electric lighting company to stop dividends or to reduce capital stock in order to make good in any one year an extraordinary depreciation charge, due, for instance, to the replacement in the year of old type machinery with new, in order to meet a public demand for a higher grade of service. Such extraordinary charges must be financed according to well understood rules. The loss of value of the old machinery does not occur in an instant, but is a process continuing through several years. So far as it is possible, this loss of value should be anticipated by charges made in advance—in other words, by the accumulation of a renewal fund. But where this has not been done the charges should be distributed over a proper period with due regard to all interests involved—in other words, so as to secure the greatest good for the greatest number. The principle is all important. The detail as to how a proper depreciation charge shall be put on the books is a matter to be disposed of in the most convenient manner.

IN CONCLUSION.

Having recited my premises, I now state my proposed policy as a recommendation, as follows:

I recommend that the association declare by resolution:

1. That a municipality may properly provide for public lighting either by the ownership and operation of an electric lighting plant, by the operation of a contractor under lease of a municipally owned plant, or by contract with the owner of a private plant.

2. That the supply of electric light to private users is not properly a municipal function.

3. That the performance of public lighting under contract by a private plant in connection with the supply of electric light to private users is essentially the method of least expense.

4. That the existence of two electric lighting plants in the same territory is an economic error tending to increase the cost of production, and thereby the selling price; and that the maintenance of competition is to the detriment of the public.

5. That public lighting by contract should be performed at the lowest price consistent with a reasonable profit on the value of the investment; that no electric lighting contractor should demand more than such a profit, and that each municipality should protect the contractor in the enjoyment of his profit, and against impairment of his investment, in order that a minimum profit may become reasonable.

6. That in order to adjust prices in the absence of competition it is necessary that costs be ascertained and prices approved by a competent authority, acceptable to the public as well as to the contractor.

7. That in the absence of a constituted authority competent to ascertain costs and prescribe prices, members having public lighting contracts under consideration should endeavor to have the adjustment of the contract price undertaken by a temporary commission, or arbitration committee, who will adopt as the basis of adjustment the principles set forth in these resolutions, particularly in resolution number 5.

8. That there is no essential difference in the organization of municipally owned plants requiring a different analysis of costs from that which is proper for private enterprises, and that the publication of the costs of municipal lighting plants properly analyzed is beneficial to the electric lighting industry. Further, that the similar publication of the costs of private plants is desirable, but is at present impossible because of its advantages to actual or possible competitors.

In conclusion, I desire to say that the tendency of public opinion appears to be toward some interference by and on behalf of the public with corporations performing so-called public services. Such a tendency is a concomitant of our social progress. It is not merely a temporary surge, but is a part of a general movement. It cannot be withstood, but may be guided into proper channels. The general result of any such movement is for good; the damage which is done to individual rights is incidental and is more often the result of needless opposition by the individual. In this matter of public lighting the right of the community to interfere is so evident that it has been one of the first subjects considered, and will be one of the first disposed of; and its priority in time will establish its disposition as a precedent for the future disposition of similar questions. There is immediate need for clear thinking and for well-considered speech and action—for speech telling the public that electric light companies desire to do business according to the golden rule, and for action plainly in conformity with the speech. I believe that this association can appropriately speak for its membership, and that its members are willing to live up to the principles which the association may enunciate.

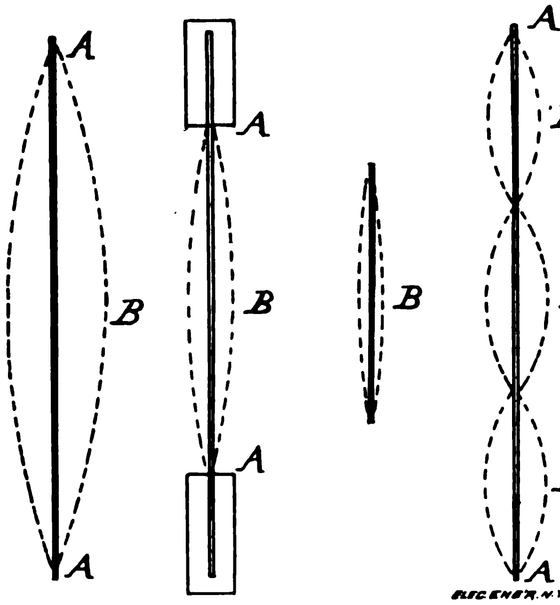
TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work.—XV.

BY A. E. DOBBS.

INSPECTION OF APPARATUS.

THE first thing I should do after an examination of the switches, generator and ringing apparatus would be to take the transmitter apart. The tendency among many manufacturers of telephones has been to make the transmitter diaphragm too small, which is theoretically wrong; and another is to spread the granulated carbon out over the whole back side of it, which is wrong again; and the fact that some of these have



FIGS. 44, 45, 46 and 47.

attained a fair measure of success, does not prove that the theory is wrong, but rather that the small variations of current used in telephone practice will be transmitted in spite of inefficient appliances.

Some makers are already beginning to find this out, and we find the carbon diaphragm constantly getting larger and the back plate for holding the granules getting smaller, while others have abandoned the carbon diaphragm altogether, using

a thin sheet steel in its place, producing a transmitter which talks and acts much like the American Bell solid back, which has been the most powerful and efficient instrument in the recent past; and we may add, has never been excelled in commercial practice except by those mechanical contrivances known as the acoustic telephone, which had a diaphragm at least six inches across. Up to their limit—which is about two miles—these possessed a perfection in transmitting conversation which has never been possessed by their electric rivals, and while their troubles were many and various, no electrical instrument on the market has enabled people to carry on a conversation with other persons from all parts of an ordinary room.

Were it not for the fact that it is so sensitive to weather changes, parchment, which was largely used in these instruments, would be an ideal material for both transmitter and receiver diaphragms; but even when covered with shellac it would require considerable attention and adjustment. Even carbon has its faults, one being its porosity, which allows dampness from the breath to work through to the granules on the back side, and most of the "packing" in the Hunnings type of transmitter comes from this cause, the moisture causing the granules to stick together.

Some makers cover the front of the diaphragm with varnish, which is a very good way, and one uses a thin layer of oiled silk, which, it seems to me, must have a slight muffling effect, though he takes so much pains with other parts of his instrument that he gets good results in spite of it.

This quality of carbon has led some manufacturers to the use of steel in their diaphragms, which has not this objection, and which is very sensitive to sound waves, though it has a metallic tone, which is objectionable.

The size of the diaphragm is of more importance than at first appears, for, in the most powerful transmitters, the free swinging surface of the diaphragm has a diameter of about three inches, and if I were manufacturing telephones I should experiment with still larger sizes. One of the best telephones I ever talked over had a cork diaphragm and a vibrating surface of about six inches. One manufacturer to whom I spoke in regard to this referred to the damper spring used on all Bell instruments to prevent too free a vibration, but this is simply used to prevent the resonance of the steel diaphragm, and is always used with a cushion of soft rubber; and every instrument man knows that should this rubber become worn out or brittle, or the spring a little too tight, that the conversation weakens proportionately. Those who have studied acoustic and musical instruments understand this perfectly.

Our present knowledge of vibrating surfaces indicates that the diaphragm vibrates as a whole, as shown by Figs. 44, 45 46 and 47. A glance will suffice to show that in order to swing freely the edges of the diaphragm should not only move freely, but that the range of greatest variation between the diaphragm and back contacts would be at the centre (B). In Fig. 45 notice how the vibration is reduced by having the edges tightly clamped, and in Fig. 46 the difference between a small one and the one shown in Fig. 44.

In the instruments known as the "solid back" there is a small button fastened to the centre at B, which still further assists in swinging this centre to and fro; and we may mention that the acoustic telephones also had a button in the centre for the same purpose. Even if the diaphragm vibrates in nodes, as shown in Fig. 47, the centre is still the most important part.

And carbon granules placed all the way up and down the width of this surface only retard its movements, and the battery variation caused by the movement at the centre may be almost completely neutralized by the comparatively stationary carbon at the edges.

Of course, there is such a thing as too free a vibration, in which case we would get loudness, at the expense of clearness, and this explains in a measure why the long-distance telephone is sometimes heard more distinctly at two or three hundred miles than when used for local business. In the former case the lighter over-tones, which have a tendency to jumble and confuse the articulation on short lines, are eliminated by the longer line resistance, which, while leaving the articulate sounds somewhat weaker, also frees itself from the objectionable ones. The form of the mouthpiece also has more to do with the talking qualities of a transmitter than is generally supposed. It should not lie too close to the diaphragm, as the back pressure of the air in the confined space would muffle it, nor should there be too much space, as much of the concentration effected by the mouthpiece would be lost.

LITERATURE

Publications and Proceedings Reeeived.

VOL. 14, No. 2, of the proceedings of the Engineers' Society of Western Pennsylvania, containing the minutes of the regular meeting of February 15, and the lecture before the chemical section on "The Municipal Laboratories of Hamburg, Germany," by J. O. Handy, and the report of the Committee on Roads and "the Relation of Our Rock Formation."

THE CANTON LECTURES ON "GUTTA PERCHA," by Dr. Eugene F. A. Obach, F. I. C., F. C. S., M. I. E. E., delivered before the Society for the Encouragement of Arts, Manufactures and Commerce, London, November and December, 1897. The book contains three lectures, the first being on the raw material, the second on the cleaning processes and the third on the cleaned material. The book is profusely illustrated, and is a complete and interesting treatise on this very important topic. A historical treatise and a number of valuable tables are appended to the book.

A LECTURE ON "GAS AND OIL ENGINES," delivered by Thomas L. Wilkinson before the Colorado Scientific Society in Denver, March 5, 1898. The author treats the subject in an exhaustive and practical manner, showing the advantages and disadvantages of the most modern types of gas and oil engines and illustrating his lecture by numerous tables and illustrations.

VOL. 12, NO. 7, OF THE SIBLEY JOURNAL OF MECHANICAL ENGINEERING, published by the students of Sibley College, Cornell University. It contains a portrait and short sketch of Prof. H. Wade Hibbard, the recently-elected principal of the new graduate school of railway mechanical engineering of Cornell University, and articles on "Electric Railway Motor Design," by Messrs. E. C. Sickles and E. A. Wagner; "Singular Stress-Strain Relations of Rubber," by Prof. R. H. Thurston; a new art of industrial drawing, department notes, editorials, etc.

UNIVERSITY OF WISCONSIN. A very handsome pamphlet, measuring 11x15 inches, entitled "Picturesque University of Wisconsin," which was issued in commemoration of the fiftieth anniversary of the college, and was edited by William Herbert Hobbs, has been received. It contains a complete history of the university and a description of the various schools of the university and a few hundred illustrations. A great deal of space is devoted to the electrical engineering department, which is in charge of Prof. D. C. Jackson. Judging from the description and the work done by this department, it certainly shows that the electrical engineering course ranks among the most practical taught in any of the American universities. It is interesting to note that in connection with this department is a laboratory for electrolysis, which is probably the first thorough equipment of the kind that has been installed in an American engineering school.

ACADEMY OF SCIENCE, OF ST. LOUIS. An illustrated pamphlet entitled "Discussion of Series Dynamo Machines," by Carl Kinsley, has been received, and is an abstract of a paper read before the Academy of Science, of Louis, April 18, 1898. It contains valuable data on and a thorough discussion of fundamental considerations from which the dynamo and motor surfaces are obtained, and a generator driving a single motor running at constant speed under all loads. Also valuable data obtained from tests of particular machines. The pamphlet is No. 7 of Vol. 8 of the Transactions of the Academy.

WORCESTER POLYTECHNIC INSTITUTE. The catalogue for the current year of the Worcester Polytechnic Institute, Worcester, Mass., has just reached this office and contains much valuable information on the splendid technical courses of

this institution. The electrical engineering course requires a thorough training in mechanical engineering, to secure which the work of the first three years is made practically the same as that of the mechanical department. It is considered of equal importance that considerable time be devoted to purely electrical engineering subjects, so that those students who have taken two years' work in mechanical engineering, and wish to follow the electrical course may elect to do so at the beginning of the junior year and become candidates for the degree of S. B. in electrical engineering. In the senior and graduate years extended courses are offered on the theory and technical application of electricity, in laboratory work and in electrical design, together with advanced space in related lines of engineering work. In connection with these departments should be mentioned the Salisbury laboratory, the magnetic laboratory, the engineering laboratory, power laboratory, hydraulic testing plant and the Washburn shops. We have also received Vol. I, No. 3, of the Journal of the Institute which is a very creditable publication, and contains in this March issue the following articles: "The Boston Subway," "History and Development of Triangulation in Massachusetts," "Printing of Cotton Fabrics," "Modern Thermodynamics," "The Development of a School of Electrical Engineering," "The Efficiency of the Steam Separator," and others.

LETTERS TO THE EDITOR

Hunter Car-Control Patents.

In your issue of June 16, page 681, the letter from me which you published gives the impression that the exclusive license to all of the controller patents of the Electric Car Company of America passed to the Thomson-Houston Electric Company. I wish to correct this, for, as a matter of fact, the Thomson-Houston Company, and through it the General Electric Company, only have a license for the exclusive use of these inventions upon trolley railroads or such roads as supply the motors with current by means of line conductors. The rights under these patents for all electric vehicles using storage batteries, such as carriages and accumulators, I caused to be transferred to the General Electric Automobile Company, which has been recently organized, and whose headquarters are in the Bourse building, Philadelphia.

R. M. HUNTER.

NEWS AND NOTES

Brooklyn Elevated Begins Its Bridge Service.

ON the morning of Saturday, June 18, the Brooklyn Elevated Railroad Company, who are equipping their extensive lines with electricity, as described in our issue of March 3, inaugurated their through service from Manhattan Borough to Manhattan Beach, by running a special train over the entire route without making a single stop. The guests who had been invited by the railroad company filled the five cars, which left the Manhattan end of the bridge at 11.30 a. m. The run was made direct to Sheepshead Bay and Manhattan Beach, via the Fifth avenue line, the inclined plane at Thirty-sixth street and then leaving the tracks of the Culver route, over the Long Island Railroad's Manhattan Beach division. The train was propelled from the terminal by means of one electric motor car, equipped with four 80 horse power Walker motors weighing 3,900 pounds each, until it reached that portion of the structure where the cable was picked up by the grips on the other four cars. These are fitted with side doors and are similar to regular bridge cars. As the train emerged from the Brooklyn terminal one of the elevated locomotives was coupled on and the train was propelled by steam to the seashore. This is the first time on record that a train propelled by electricity, cable and steam has been run direct from Manhattan to the seashore, and the honor of operating the train fell to General Superintendent I. D. Barton of the Brooklyn "L," who ran the motor and the engine on the trip down. From the Manhattan terminal of the bridge to the Manhattan Beach Hotel the run was made in 37 minutes and 50 seconds. This was unusually good time and was due to the fact that no stops were made. The railroad officials say that the regular running time for this distance, with regular passenger trains and all stops, will be fifty minutes. The trolley roads cover the same distance in a little over an hour. At the seashore an elaborate luncheon was served at the Manhattan Beach Hotel and the three hundred guests of the elevated road completely filled one of the big dining rooms.

In the words of ex-Mayor Fred. W. Wurster: "The running of through elevated trains over the bridge and the consequent increase of transportation facilities to the people of Brooklyn, as well as the resultant benefits in the shape of expected increased population and material growth, makes this an event of historical importance to this borough."

Cable Cutting.

Mr. James Brown, superintendent of the Direct U. S. Cable Co., of this city, sends us as worthy of note the following item from the London "Electrician" of June 10:

"With reference to statement made in daily press, that if the United States interrupt telegraph communication with Spanish colonies, Spain will retaliate by severing the cables between the United States and Europe, we desire again to point out in the strongest manner the futility of such an attempt, which would only result in injury to neutral property, without effecting the desired object, and would inevitably lead to heavy claims for damages, to say nothing about the practical impossibility of breaking some twelve or thirteen cables before those first severed are repaired. We have it on the authority of one of the Atlantic companies that they have transmitted readable code words through a cable 500 miles long, broken about midway, by means of apparatus invented by A .C. Brown, of the Single Wire Multiple Telephone Signal Co."

Electric Power From the Catskills.

The Ramapo Water Company has a plan to develop electrical energy in great quantities from the watersheds of the Catskill Mountains. It has obtained control of over 1,000 square miles of watersheds in the counties of Rockland, Orange, Ulster, Sullivan, Delaware, Greene and Schoharie. The company believes that enough power can be developed to run all the electrical and surface cars in this city.

Mr. Lauterbach, counsel for the company, says that the details of the plan were not ready to be made public. "If Niagara Falls were near our doors the city would naturally be deriving an enormous benefit from it. But as it isn't we are going to do what we can with water power that is not so far away."

La Capital Electric Railway, Buenos Ayres.

American supplies are being almost exclusively used in the equipment of the La Capital Electrical Railway, of Buenos Ayres. The rails are 90-pound grooved girder, made by the Johnson Company, the bonds Edison-Brown plastic and Syracuse soldered. The entire rolling stock was built by the J. G. Brill Company, mounted on Brill trucks and equipped with General Electric motors. The iron poles were furnished by Morris, Tasker & Co., and the overhead material by the W. H. Johns Company. In the power house three vertical Ball & Wood engines are coupled direct to Walker generators. Steam is supplied by four Sterling boilers of 250 horse-power. The plant includes Green's fuel economizer, Conover's condenser and two Worthington pumps.

BALTIMORE, MD., has voted to build a municipal system of electrical subways, under a board comprising the mayor, city register and president of the fire commissions, and with a chief engineer at a salary not exceeding $4,000 per year. Bonds for $1,000,000 may be sold for the prosecution of the work.

The Development of Automobiles.

ON the surface, in this country, there have been very few indications until recently of any activity in the field of automobile traction, but it would seem that a new departure is about to be made. The display of several vehicles at the Electrical Exhibition was encouraging, and the carriages themselves were far in advance of anything hitherto brought to notice. This month again a new type of electric carriage is being shown at the Philadelphia Exhibition, and the news comes of the formation of an important new automobile company there, as well as the entrance into the field of the Indiana Bicycle Company, a well-known, leading concern in the West, which has acquired control of the American Electric Vehicle Company, of Chicago.

All this is promising and appears likely to put this country in line with France, where automobiles are shown by the present exhibition in Paris to be both numerous and popular. In some respects, these developments may put us ahead of France, where promoters and engineers are still pottering along with oil, gas and steam locomotives that will assuredly drop to the rear at no distant date, while electrical machines will as certainly come to the front. In this country all the more serious efforts would now appear to be making along the line of electricity, and work in other directions has the air of petering out. We believe that the electrical methods in use will soon improve materially. We can but agree with Mr. J. T. Niblett in his recent address before the Self-Propelled Vehicle Association at Liverpool, when he said: "The modern secondary battery leaves very much to be desired, but still there are several very good batteries for this purpose obtainable." One of the chief points now to be worked out is that of supply, and we cannot see why our direct current low tension stations should not, in all the large cities, be able to build up a large new business in service of this character at specific sub-stations where cabs, express wagons, buggies and other vehicles can plug in, charge up and pay for what they get there and then, or under contract. In minor cities, also, there is an excellent opportunity thus coming for a new market for current, and 1900 should see the streets of America much fuller of electric automobiles than they now are of trolley cars.

The "Demon" Fan Motor.

IT had to come at last, and the "deadly" trolley now finds an associate in crime in the "demon" fan motor, as the New York Journal, with wonted understatement, calls it in a recent news item. We have heard the fan motor described as "the pneumonia screw," but this is much stronger language, although people who have interposed their fingers among the whirring blades have perhaps matched it. The Journal tells how in a palatial free lunch saloon in aristocratic Jersey City a fan motor, at high noon, when the lunchers thronged thickly, tipped off its perch, gashed the face of a bartender and plunged madly into the dishes of tongue, beets, crackers, cheese, etc., "with a clatter that could be heard for blocks." The lunchers fled in dismay, the free spread was ground to powder, and the motor "seemed to pursue in turn everyone within the length of its cord." One man who went to the bartender's aid had his legs cut by the fiercely revolving blades, and there was promise of further carnage when a heroic policeman bethought himself to turn the key switch and stop the current. By this time "the saloon was a mass of hash, broken dishes and two bleeding men," and the fan motor had won for itself a name as the "demon" and a place in history. When we remember that idle stockbrokers sometimes use fan motors as a means of gambling by putting numbers on the blades and betting on them, it will be seen that we are dealing with a new social monster which must be forthwith suppressed—just as the "deadly trolley" was.

The Use of Röntgen Rays on the Battlefield.

PEACEFUL as its mission is in advancing and spreading civilization, not less potent is the influence of the electric current in its numerous applications upon modern warfare. Whether this relates to its innumerable uses on shipboard or the defense of our harbors, the transmission of intelligence by means of lights, telegraph or telephone, or the explosion of mines, in every department has it become a useful and indispensable servant when entrusted into intelligent hands. Little, however, has been said, and not much more, perhaps, has been done, regarding the use of the Röntgen rays on the battlefield, in the hospitals and tents, for relieving the pains of wounded and suffering soldiers. This fact is not to be ascribed to any fault of the apparatus or inadequacy to do the work for which it is intended, but it is due rather, judging from recent remarks by Surgeon-General Sternberg, to a prejudice against, or too little knowledge of, the intelligent use of the rays. This is very much to be regretted. If it is evidence of utility the authorities want, let them peruse the recent lecture by Surgeon-Major W. C. Breevor, before the Royal United Service Institution of England, who based his remarks on the result of experiences he gained during the recent operations on the Northwest Frontier of India. He dwelt at length on the employment of Röntgen rays in military surgery and proceeded with the aid of magic lantern slides to give cases of interest from the campaign. These consisted of bullet wounds sustained by officers and men who had injured bones, joints and internal organs, baffling the skill of surgeons to ascertain their exact position, and which, but for the application of the X-rays, must have resulted in amputation of limbs and probable loss of life. The pictures included wounds in the arm, chest, leg, back, finger and other parts of the body. In every one of the instances enumerated,

the bullets were, by the use of the rays, successfully removed, the men subsequently rejoining their comrades at the front. He then gave details of the requirements of an X-ray outfit for easy transport in the field.

This is the experience of an intelligent English officer, which deserves recognition, and has been repeatedly borne out by experiences in our own country in times of peace. Should the officials decide to employ such apparatus on the proper scale, electrical manufacturers could furnish portable outfits in short order, any number of men could be found or trained to handle them, and by a speedy introduction of this great life-saving device many of the horrors of war may be alleviated or removed.

The Value of Consular Reports to the Electrical Industry.

DURING these stormy times and diplomatic complications we have heard considerable about the necessity of the proper training of the foreign representatives in whose hands are so largely entrusted the interests of our country. Not alone, however, should they possess a knowledge of the law of nations so as to be able to defend our rights and honor, but they should be equally well trained in the commercial interests and needs of the people. They should carefully guard and increase our commerce, and lend their aid to the extensive introduction of American machinery and products. That this last matter has not been lost sight of by some of our representatives abroad is evidenced by a recent letter of United States Consul Liefeld at Freiburg, Germany, to the Scientific American advising American manufacturers of the fact that an electric railroad is about to be built at that place and enclosing circular letters, plan of the city, plan and profiles of the projected enterprise, etc., and advising them to whom and up to what time to submit their bids. In a similar manner other consuls from time to time publish items of great interest to American electrical manufacturers, so that no large electrical concern should now be without the consular reports issued daily by the Bureau of Foreign Commerce, Department of State, and sent free to anyone on application. Consul Liefeld's course is to be highly commended and should be widely followed by his associates to whom, we are sure, the columns of the technical press are freely open at all times.

The Municipal Right to Govern Wrong.

ONE of the interesting papers at the Chicago N. E. L. A. convention was that of Mr. Dow on the fundamental principles of municipal ownership and operation. The paper is the more valuable because it is moderate in tone, even in temper, and argues the question out with sweet reasonableness. The paper closes with a series of propositions which Mr. Dow wanted the association to adopt, but which were not, we believe, altogether acceptable, and which are not likely to become its platform under existing conditions. For instance, Mr. Dow wished to have it declared that "a municipality may properly provide for public lighting either by the ownership and operation of an electric lighting plant, or, etc." Now that is the very principle the members are likely, individually and collectively, to fight tooth and nail; and one which we should certainly object to, even if every one of them voted themselves thus out of existence. There are good municipal plants, and many good men running them, but we believe and are convinced that as a general thing it does not pay any community to undertake for itself a service it can get done under contract. We say "does not pay" and are willing to rest the issue on that ground alone. There are other grounds, and broader, but that will suffice.

OBITUARY

Bernard Moebius.

Bernard Moebius, inventor of the electrolytic process of parting and refining gold and silver which bears his name, died recently on board the Kaiser Wilhelm der Grosse while on his way to his old home in Germany. Mr. Moebius succeeded in 1884 in solving the problem of economically and rapidly extracting the precious metals from their ores by electricity. He improved his invention in 1895, and now both the old and new processes are in successful operation in Europe, Mexico and the United States. Mr. Moebius engaged in mining in Germany, Austria, Spain and Mexico before settling in the United States, of which he became a citizen.

LEGAL NOTES

Foundation Reversible Trolley Patent Suit Dismissed.

THOMSON-HOUSTON ELECTRIC CO. VS. UNION RAILWAY CO. AND WALKER CO.

Judge Shipman in the U. S. Circuit Court for the Southern District of New York has dismissed the above suit for infringement brought under the Van Depoele patent No. 495,383, claims 11, 12 and 13, covering the use of the reversible trolley. Judge Shipman noted that the patentability of the three claims had already been decided against in the Winchester avenue case by Judge Townsend, under this patent and No. 495,443, but said in considering the matter again: "The necessities of the new underrunning trolley system called for the improvement, but the idea of pivoting the contact arm to a rotating support, to which the spring is also attached, rather than to the car, must have been within the capacity of the ordinary mental equipment of the skilled mechanic."

No Appeal in the Milwaukee Four-Cent Fare Case.

It is stated that the attorneys for the city of Milwaukee in its unsuccessful suit against the Milwaukee Electric Railway and Light Company, to enforce the Common Council's four-cent-fare ordinance, had virtually determined not to appeal the case further. The city attorney is quoted as saying that any additional litigation would only lead to useless expense.

The defendant company, which received a favorable decision in the suit about a fortnight ago, will, of course, stand on the verdict, but would have preferred, it is said, to have had the case taken through the Appellate and Supreme Courts, in order to reach a final adjudication. This was regarded as of especial importance in the present case, because it is "new law," and a final decision in the highest courts would have made it directly applicable to all similar cases which might occur anywhere in the United States.

Diehl Motors.

The Diehl Manufacturing Company notify us and the trade that they have brought suit against Royce & Marean, of Washington, under patents Nos. 465,360, 465,361, 537,679 and 585,250, relative to fan motors.

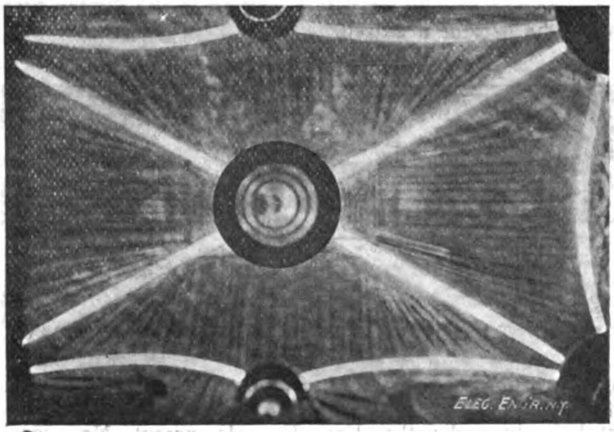
THE OMAHA EXPOSITION has been duly opened by President McKinley with the aid of the telegraph and the long distance telephone, and the exhibits are rapidly getting into shape. The show is a very fine one and typical of the central West.

THE PHILADELPHIA ELECTRICAL EXHIBITION.

JUNE 6 TO JULY 6.

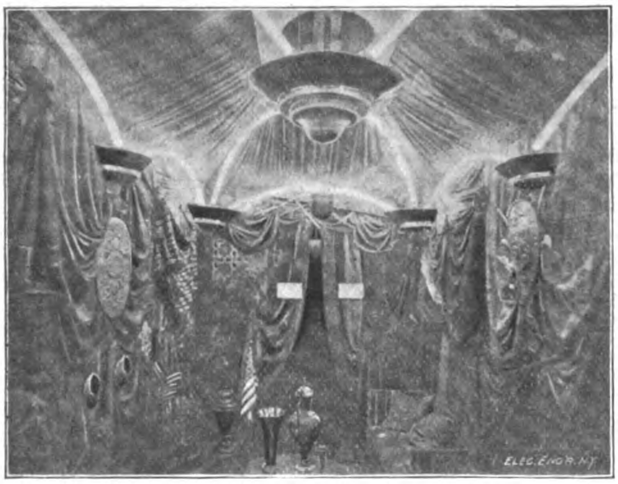
The Moore Vacuum Tube Exhibit at the Philadelphia Electrical Exhibition.

UNDOUBTEDLY the feature of greatest interest to the visitors at the exhibition, both on account of its novelty, as well as the beauty of its arrangement, is the Turkish smoking room illuminated by means of Moore's vacuum tubes. Very few people discover that the vacuum tubes used in this room are the same that were used on the arches of the beautiful chapel at the recent show in New York. They appear here



ARRANGEMENT OF TUBES ON CEILING OF THE MOORE TURKISH SMOKING ROOM.
(Photographed by light of tubes.)

under entirely different conditions. Instead of adorning a sacred edifice, they now light up the rich colors of the oriental hangings of a Turkish smoking room. The distribution of the tubes, producing an ideal effect, is shown by the accompanying illustrations. The photograph of the interior, as well as that of the ceiling was taken by the light of the tubes themselves, which brought out the beautiful details of the richly colored tapestry, as well as if daylight itself had been used. The apparatus for producing the light is the same as that used at the New York



INTERIOR OF THE MOORE TURKISH SMOKING ROOM.
(Photographed by light of Moore Vacuum Tubes.)

show, and was described in our pages in the issue of May 12. Many favorable comments have been passed by visitors on the great similarity between this light and daylight, its softness and great light giving power without producing any heat. Mr. Moore has now so far perfected his apparatus as to be able to produce a bright steady light, practically devoid of fluctuation or interruption. He has demonstrated its adaptability for interior illumination, certainly showing by the two exhibits its wide range of usefulness. Reliable data as to the efficiency and light-giving power of these tubes will, we understand, soon be forthcoming, and it will be awaited with a great deal of interest by every one.

Some Exhibits at the Philadelphia Electrical Exhibition.

WE make running note below of several of the principal exhibits:

The Bell Telephone Company, of Philadelphia, have a long distance telephone and public pay station.

American Feather Flower Company, 144 North Seventh street, Philadelphia, Pa., have show case with exhibit of feather flowers and an exhibit of the manufacture of feather flowers with decorative lamps inserted.

United Electric Improvement Company, Nineteenth street and Allegheny avenue, Philadelphia, Pa., manufacturers of direct current dynamos and motors, alternating current apparatus for central stations, switchboards and instruments; rewinding armatures and general electrical repairs; incandescent lamps for all systems of electric lighting, colored and ornamental lamps, miniature lamps of any candle-power or voltage. This company exhibit in their handsome booth, an illustration of which appears on this page, a great variety of the above products. On a

EXHIBIT OF THE UNITED ELECTRIC IMPROVEMENT. CO.

plush-covered panel at the back of the booth are arranged innumerable incandescent lamps and in the centre is a 12-inch fan motor in operation. Above the board are placed several "Mogul" lamps of 150, 250 and 500 c. p., 110 volts. They have in operation a complete incandescent lamp manufacturing plant and make miniature lamps on the spot, which, with pin attached, they give away as souvenirs. They also exhibit bipolar and multipolar generators, and a mercurial vacuum exhausting pump. Special carbons are also shown and the exhibit is in charge of Mr. W. E. Smith, assisted by Messrs. W. and James T. Jukes.

American District Telegraph Company, 1031 Chestnut street, Philadelphia, Pa., have a public telegraph office.

Dr. Marcus Rothschild, Bourse Building, Philadelphia, Pa., has an exhibit of electrical power lens grinding apparatus.

George M. DeGinther, Eleventh and Walnut streets, Philadelphia, Pa., shows Holaphane globes of great variety of styles and sizes in a handsomely fitted up booth.

Alfred F. Moore, 200 North Third street, Philadelphia, Pa., has an exhibit of single and double cotton-covered armature wire, single and double silk-covered wire, annunciator and office wire; weather-proof wire, fire and weather-proof wire, telephone cords, incandescent lamp cords, telephone switchboard cords, telegraph switchboard cords, rubber-covered line wire and special duplex telephone line wire.

Williams, Brown & Earle, 918 Chestnut street, Philadelphia.

Pa., show the electrical centrifuge for the rapid sedimentation of liquids by means of centrifugal force, and for the examination of blood, and for bacteriological work. The following electro-therapeutic apparatus is also shown: The electro-galvanic controller, Dr. Massey's electric controller and galvanic cancer battery and the electric cautery controller. Also the following electric projection apparatus: The electric projection magic lantern, spectroscope and microscope.

Morse, Williams & Co., 1105 Frankford avenue, Philadelphia, Pa., exhibit several elevators, as follows: Large size direct-connected winding drum electric elevator for 350 feet per minute car travel for passenger service, or 10,000 pounds at slow speed for freight service, with attached motor and variable speed controller. Small size factory belt ceiling machine driven by reversible motor and single belt; with motor and controller arranged to show usual manner of erection and operation in factory. Model of direct-connected electric passenger elevator, suitable for residence service and adapted for automatic push button control. Model of Hindley worm and wheel showing type of worm and wheel used by Morse, Williams & Co. in all their direct-connected electric and belt-driven hoists.

Walker & Kepler, 531 Chestnut street, Philadelphia, Pa., make an exhibit of Lundell dynamos and motors, direct-connected fan outfits, organ blowing outfits, ceiling and desk fans and Sprague electric elevators; telephones, heating apparatus, switchboard instruments, bell and gas lighting supplies, electric lighting supplies of all kinds; iron-armored conduit and fittings, pole-line material; Pioneer arc lamps, Imperial incandescent lamps; gas, electric and combination fixtures and shades.

The Sprague Electric Company show Lundell fans and motors and an Estey Phonorium with Lundell motor outfit.

Westinghouse Electric and Manufacturing Company exhibit a 60 k. w., 190 volt multipolar generator, designed for charging storage batteries, direct-connected to a new 3-cylinder type Westinghouse gas engine. This engine embodies in a general way features which have made the Westinghouse steam engines so popular and successful; the upright, self-contained construction and self-lubricating principle being particularly apparent. The valve actuating mechanism is located inside the crank case where it is protected from dirt and grit and where it is constantly and copiously lubricated. The valves themselves are of the "poppet" type, positively actuated, impossible to clog, and having no rubbing surfaces to wear or cut. One of the main difficulties with gas engines has been that of regulation. The good regulation of this engine is secured by building it with three cylinders and giving several impulses at every revolution. It regulates for changes of load by varying the amount of the explosive mixture delivered at a charge, but it receives several impulses at every revolution, whether running fully loaded or entirely light. On this account it compares favorably with the best steam engines in smoothness of running and regulation.

Standard Fireproofing Company, Perth Amboy, N. J., have an exhibit of fireproofing and clay conduits, as described in our columns in a previous issue.

Hawthorne & Sheble, 604 Chestnut street, Philadelphia, Pa., show the Burton electric welding water forge in actual operation.

Otis Electric Company, New York City, are represented by Stokes & Parrish Elevator Company, 702 Bullitt Building, Philadelphia, Pa., with a small elevator with automatic push button operating device in operation.

Rudolph M. Hunter, 926 Walnut street, Philadelphia, Pa., has an exhibit showing the position of Mr. Hunter's inventions in the field of electrical progress. It includes: A third-rail electric railway system, 1-20th full size, showing Mr. Hunter's improvements with special reference to train regulation and motor trucks. Series multiple car controller, showing Mr. Hunter's development and early work. A small working model exhibits how the controller operates. The modern electric car truck with the motors hinged to axles, etc., now employed to the exclusion of all other methods. Exhibited by working models. One of Mr. Hunter's early trolleys and the first of its class. A large searchlight of special design, said to be the largest made in this country. A searchlight having horizontal carbons and reflector, invented in 1881. A projector adapted to searchlight purposes, or for stereopticon and moving photographic effects. A method of regulation without resistances. A miniature alternating transformer system illustrating methods of operation in large plants for local and long distance transmission, such as in use at Niagara Falls. Electric switches and meters. A series of volumes showing Mr. Hunter's inventions; a number of photographs showing original and later constructions under Mr. Hunter's inventions, and publications of Mr. Hunter in 1882-3-4 relating to electric railways, lighting, telephony, etc.

Vallee Bros. & Co., 625 Arch street, Philadelphia, Pa., show electrical heating apparatus, sad, laundry and soldering irons, Whitney Electric Co. volt and ammeters, Zimdars & Hunt panel feeder boards and knife switches, Victor lamps, miniature lamps, Paragon desk fans and Diehl ceiling fans. The booth is very tastefully arranged and beautifully illuminated.

The International Correspondence Schools, Scranton, Pa., are represented by Mr. E. B. Duncan, the manager, who explains the system of instruction.

General Electric Company, Schenectady, N. Y., show Thomson electric meters for two and three-wire systems direct and alternating currents, Thomson-Houston alternating fans and arc lights.

American Electric Meter Company, Ninth and Montgomery avenue, Philadelphia, Pa., show three 40 ampere three-wire meters, direct current in series; three 20 ampere, three-wire meters, direct current in series, and three 10 ampere, three-wire meters, direct current in series and lamp bank for same. A giant electromagnet and apparatus for testing the strength of the same by means of armatures. Filings spread on glass surfaces and cases for showing the formation of magnetic fields. Demonstrations are made hourly throughout the day.

Sawyer Electrical Company, Sawyer Building, 1308 Arch street, Philadelphia, Pa., show the Nowotny enclosed arc lamps; Faries lamp fixtures; a Triumph Electric Co. 7½ h. p. motor, and Sawyer elevator door locking devices, telephones, etc.

W. P. Dallett, 49 North Seventh street, Philadelphia, Pa., shows a Deming electric pump operated by an Excelsior motor.

H. R. Worthington, 724 Arch street, Philadelphia, Pa., have in operation a 250-gallon per hour house tank pump and a 500-gallon per hour duplex steeple power pump, direct connected to a Crocker-Wheeler motor, pumping the water used for the electric fountain and cataract. There is also shown a 1,000-gallon per hour house pump, direct connected to a General Electric motor.

Stokes & Parrish Elevator Company, 702 Bullitt Building, Philadelphia, Pa., have a working model of electric-hydraulic elevator, designed and constructed by D. W. C. Suplee, Glenolden, Pa.

Helios Electric Company, 1229 Callowhill street, Philadelphia, Pa., make an exhibition of enclosed arc lamps of great variety of design for indoor and outdoor service. Novel and beautiful designs of covers are shown, which have attracted as much attention as the noiseless burning of the lamps. They are distributing a very ingenious folding circular, showing their various styles of lamps and the manner of manipulating them.

Hawthorne & Sheble, 604 Chestnut street, Philadelphia, Pa., show a great variety of phonographs, kinematographs and give recitations of phonographic speeches by public men, with hourly kinematograph entertainments to large and appreciative audiences.

Barrett & Plowman, 1312 Filbert street, Philadelphia, Pa., Eastern agents, have on exhibition the Climax steam joint clamp, which possesses many decided advantages and seems to fulfil the long-felt want for a device to repair leaks on steam joints without pulling out the pipes or shutting down the plant.

PERSONAL

COL. C. E. McCLUER, so long general manager of the Southern Bell Telephone Company in a district comprising some twenty-four exchanges in and connected with Richmond, has become general manager of the independent Richmond Telephone Company, the appointment taking effect July 1.

MR. T. AHEARN, of Ottawa, Can., has just returned home from his second trip around the world with his family. He had the pleasure of seeing the American fleet at Hong Kong not long before it sailed for Manila. He says that the American flag is welcomed in the far East, and that Britishers are enthusiastic for it.

MR. J. GEORGE KAELBER, of Rochester, was a visitor to New York last week. He had closed up many of his electrical interests some time ago, but could not resist the pressure of friends and is now engaged again in engineering a number of important deals with wonted energy and success.

ELECTRIC LIGHTING

Discussion of the Papers on Alternating and Direct Current Distribution by Messrs. H. A. Wagner and L. A. Ferguson.[1]

PRESIDENT INSULL in the chair.

Prof. Fujioka, an honorary member of the association, being called upon to speak, gave a short description of the plants and system which were carried out under his direct supervision in Japan. He advocated the use of the Edison three-wire system for the more densely populated districts, but had added single and three-phase apparatus to supply current to outlying districts. Coal, he stated, costs $5 to $6 a ton in Japan.

Mr. Wagner, in answer to questions by Mr. Thayer, stated that the effect of transformer dropping is eliminated by making the transformer practically an integral part of the feeder. The transformers of very close regulation, one per cent. or under, are connected in multiple with two or three hundred feet of mains or more in between. In answer to Mr. van Trump as to the objection to cutting the feeder transformer off the line automatically and saving the under load losses, Mr. Wagner said that the object is to make the underload losses so small that it will not be necessary to do that, as it would complicate the system considerably. In the system described in the paper the highest efficiency is at the average load, so that if a transformer was cut out and its feeder was cut out, it would decrease the average efficiency rather than raise it, as it would increase the load on the other feeders, increase the copper losses in the other feeders and other transformers, and that increase in copper loss would be greater than the iron losses which you sustain temporarily. The object is to design a system to be most efficient at the average load. With a transformer that can be accomplished successfully and the wattless current is inappreciable. The volt amperes and the watts correspond so nearly in any alternating station at full load that the increase is almost inappreciable, even in the most poorly designed station. The power factor is very high at maximum loads, and with a system of this kind the power factor should be practically 100 per cent. at all times, except for alternating motors, which lower it slightly. The part of the load that comes on the peak is principally incandescent lighting. The motor load is almost constant and the arc lighting load is much more nearly constant than the incandescent load.

Mr. Dow expressed the opinion that the feeder loss of 24 per cent. given by Mr. Wagner was exceptionally high and that 12 to 15 per cent. would be nearer right. He also stated that the initial cost of transformers in alternating current systems will pay for a great deal of copper in the direct current installations. He firmly believed in the importance of a central station being able to supply current for elevator work, and that the failure to give good elevator service will often cause the establishment of isolated plants. In his opinion the alternating current service can be wonderfully improved above its customary standard, but in the case of a densely populated district demanding the greater portion of the total supply the direct current is unquestionably the best; a less densely populated section might be supplied by the alternating system, or it can be supplied, as Mr. Ferguson had suggested, by an alternating distribution and direct current.

Mr. Ferguson in answer to a question by Mr. Wilmerding stated that the 22.8 per cent. mentioned in his paper included the total losses from the station to the customer's meter, including all the trunk line losses and the main.

Prof. Goldborough thought that the low load efficiency of a plant could be increased by improving the efficiency of the transformers. He suggested the establishment of sub-stations wherein a number of transformers could be placed together and feeders be run from the central station to the sub-station, and some of the transformers could be cut out and some of the feeders could be used in common with some of the transformers. By cutting out some of the large transformers and having a few of them fully loaded instead of many of them partially loaded, the power factor of the whole distributing system would be improved. The cutting in and out of the transformers might be accomplished by means of an electro-magnetic device operated from the central station. A system similar to this, he stated, was in use in England and on the Continent, but it does not work very satisfactorily. He said in regard to arc lamps that the efficiency of the alternating current lamp as a whole is much less than the direct current lamp and it takes more power. He denied the assertion that the Welsbach light is becoming more popular than the incandescent lamp, and claimed that it was not at all suitable for interior lighting, as it makes everything look ghastly. He advocated the use of the single-phase rather than the three-phase alternating system, as with the former closer regulation can be obtained.

Mr. Rice, in answer to Mr. Scovil, stated that at Salt Lake City current is successfully transmitted over a distance of nearly fifteen miles by a three-phase four-wire system, and the same system is in use at Sacramento over a distance of twenty miles. Mr. Rice expressed the belief that the alternating current systems of light and power distribution have a great future before them, and that the alternating current motors and arc lamps will undoubtedly be further developed within the next few years.

Mr. Pillsbury: I wish to say a few words in regard to the alternating current motor, having been identified for several years with the development more especially of single-phase machines. The question has been raised as to their power factor by one gentleman, as to their practical success by another, and as to their adaptability for the direct driving of elevators by several. Single-phase alternating current motors are now made equal, if not superior to direct current motors for general power distribution. The power factor in a well designed machine may be considerably above 90 per cent. from 50 per cent. to 150 per cent. of its rated capacity, and above 80 per cent. while the motor is developing 20 per cent. of its rated output. For general power distribution these are superior to direct current motors in point of care and attendance required, average efficiency, absence of wear, etc. To the direct driving of elevators they have not as yet been applied, but there is no reason why they cannot be adapted to this work as soon as a sufficient demand shall have arisen. The only problem met with in their application to this class of service is that of starting. There are two methods of doing this, one by splitting the phase and another by introducing a commutator. Either of these is entirely successful. It may be confidently affirmed that single-phase alternating current motors are now on the market superior to direct machines for general power distribution, and that in the near future they will be adapted to such special work as the direct driving of elevators with entire success.

Mr. Insull in a characteristic and able discussion championed the cause of the reliable and well-tried direct current system of distribution. He pointed out as a main advantage of the latter the permanency and flexibility of the system and the dependence of the choice of a system on the conditions which present themselves. He gave a splendid retrospective view of the central station industry, and stated that the house-to-house plan of alternating current distribution now in use at Chicago is not satisfactory, and the losses are enormous. He defended the "beams of copper" referred to by Mr. Wagner by saying that the size of the copper bars depended on the cost of fuel. In refuting Mr. Wagner's closing claims Mr. Insull thought that the question as to the relative cost of distribution and operation with the two systems was still an open one. As to the best regulation, he believed, that the charts exhibited by Mr. Ferguson showed a regulation as nearly perfect as could be desired. Regarding the largest territory desired and readily supplied from one station, he believed it to be simply a matter of conditions. No system, Mr. Insull said, could be more flexible than the Edison three-wire system operating during the whole of the 24 hours first from one station, then from two, then from three, carrying at the same time during the 24 hours current 13,000 feet from the point of generation with a loss so small as to be almost impossible to figure out.

In conclusion he warned his listeners to go very carefully, certainly in the large cities, about adopting a scheme over one that had received the test of time. So far as widely distributed areas are concerned, Mr. Insull said, there is no doubt that the alternating current is of great advantage, but in big centres of distribution the experience of electrical engineers the world over has shown that the one system to use, one by which we

[1]Papers read before the N. E. L. Assn., Chicago, June, 1898. Printed in The Elec. Engr., June 16, 1898.

can make money and which will enable us to keep our position, is the low tension Edison system.

Mr. Ayer spoke of the advisability of leading the discussion into a channel where the small central station man would be benefited as well as those in charge of large central station interests. He believed that house-to-house distribution is doomed, which means going to the three-wire system. Also that printing presses are very troublesome to the alternating current motor man. There is no question, he said, that single-phase motors will come and be satisfactory, but they are not comparable to the direct current motor to-day. He referred to the easy destruction of translating devices and the expense connected with replacing them, and in conclusion said: "I want to express my conviction very firmly that the old system is the best one.'

Mr. Stetson, in answer to a question by Mr. Davis, gave a brief description of a station using both the direct and alternating systems of distribution. He believed it to be a good combination, especially when a station once built and equipped with direct current apparatus wishes to supply outlying districts. In such a case recourse must be had to alternating current distribution.

Mr. Ferguson replied to several questions regarding the figures in his paper representing average voltage and the natural drop in the lines under normal conditions, which he said was 11.2 or 8.8 per cent. and the efficiency of the system of distribution was 97.3 per cent.

Mr. Insull explained this heavy drop by referring to the peculiar local conditions which the Chicago Edison Co. had to contend with. The station is now very profitably located, no carting of coal being necessary and the water for condensing and feed purposes being obtained free. It simply resolves itself into a question of balancing fuel cost against interest cost and labor.

Mr. Hubeley gave some interesting converter loss figures and stated that the all important question with the alternating station is the fact that as yet no converters without these losses have been manufactured.

Mr. Thayer presented some valuable experience with the remodeling of a transformer distribution. He reached the conclusion that it is a simple matter to adapt the Edison system of distribution to fit alternating current conditions and that there is no question as to the advisability of using large transformers both in cutting down the iron losses and in improving the regulation of the plant.

Mr. Chandler represented a station which is now running three systems, this being deemed advisable on account of inherited machinery and existing local conditions. The large transformers appeared to him to be the most economical and elastic, and by putting in the district transformers the entire system is elastic and satisfactory in every way.

Mr. Walbank drew attention to a very successful three-phase lighting plant supplying over 30,000 lights. Motors are also supplied by this system, and there is no trouble from regulation; this being done by means of rheostats. Direct currents take care of the elevator demand and everyone seems perfectly satisfied with this three-phase distribution for light and power.

Mr. Ferguson in summing up the matter for the direct current advocates stated that in his opinion the question of efficiency and percentages meant a great deal as was evidenced by the results in the new station at Chicago, where these figures were lower than in the old station, but where the cost of producing a unit of electricity, with the poor efficiency of distribution, is infinitely less. The real thing, therefore, is not the curve of efficiency, but the actual cost of the production of the unit of electricity. He refuted the argument as to the expense of copper for direct current distribution by stating that the copper only represents 20 per cent. of the underground equipment and that if there is any extra expense for copper this is easily overbalanced by the cost of the transformers in the other system. In conclusion Mr. Ferguson made the following reconciliatory statement: "It is a question whether it is fair at the present time to compare the two systems, of which one has been in use for a long time, the figures relating to which are reliable, and the other being rapidly put into practice, and the figures relating to which are in the embryonic state."

Mr. Wagner then finally took the stand and replied ably to his critics and questioners. Regarding the additional resistance in the mains where alternating current is used, he stated, that on conductors as large as 300,000 c. m., which are as large as are generally used for distributing mains, the difference between the alternating current and the direct current is inappreciable. With numerous tests on that size conductor, he found that the difference in drop with a given current, with a power factor of 100 per cent., is about 10 per cent. The actual drop is increased 1 per cent. with the alternating current. With a power factor as low as 75 per cent., which is as low as any combination of power and light would be on such a system, it is increased to 3 per cent. additionally. The 2 per cent. drop of the direct current would be increased to 2.3 per cent. The additional cost for alternating mains, three-wire system, would be practically nothing. He spoke of the noiseless operation of specially designed alternating current arc lamps, 100 of which are in constant operation in St. Louis, and mentioned the satisfactory installation of six to eight elevators using two-phase alternating current motors. Replying to Prof. Goldborough's suggestion as to sub-stations and the cutting out and in of transformers, Mr. Wagner believed that with a distribution efficiency of slightly over 96 per cent. on the average load it would seem inadvisable to go to this extra expense. Then the use of sub-stations complicates the system and simplicity, without great cost of operation, merits serious consideration. He also believed that the series arc lamp for commercial lighting would soon be a thing of the past. He commented at some length on the advisability of moving a central station to one side of the district to be lighted and reaching out into new districts by employing rotary transformers conveying current to a distant high potential alternating current transformer and retransforming it to a low potential, and through rotary transformers to direct current. Such a system is in use in Brooklyn by the Brooklyn Edison Co. (described in The Electrical Engineer January 6, 1898). This fact and the one that the Chicago Edison Co. is preparing to do likewise showed the economy in this method of distribution. Mr. Wagner, however, expressed the opinion that it is undesirable to mix systems of distribution as the multiplication of machinery and the additional investment for the reserve is a very serious factor. In answer to Mr. Walbank he said that where lighting is the principal factor, the three-phase distribution cannot be made to regulate as well and give as satisfactory results as the single-phase or direct current.

Series Arc Lamps on a Railway Circuit.

The following remarkable and unique incident has recently been reported from Kansas City, Mo. On Saturday, May 14, Kansas City was visited by a hailstorm the like of which has never been equaled in the memory of the oldest inhabitants. The ground was covered with hailstones, the smallest being about the size of moth balls, and ranging from that size to two and one-half pounds, and somewhat larger than door knobs. As can be imagined, the electrical wires suffered materially. At about 10:30 on Sunday morning the station manager at the plant of the Kansas City Electric Light and Power Company was surprised to receive a telephonic inquiry of "Why don't you shut down your arc circuit?" An investigation showed that three arc circuits had become crossed on the trolley and that thirty arc lights had been burning since 5:30 a. m. As it happened, the lamps got the current "upside down," and the result was thirty beautiful examples of the heating effect of the electric arc and thirty lamp bases molten into as many lumps of brass. We are indebted to Mr. J. L. Morgan, the city electrician of Kansas City, for the above interesting details.

CORUNNA, MICH. Messrs. G. B. Clarke and C. M. Holley have put in operation the new Corunna Electric Lighting Company's plant, with a paid in capital of $4,000. It is a direct current system with Card generator of 50 k. w., driven by an Armington & Sims engine of 75 h. p., with an Atlas boiler of 100 h. p. The concern will be glad to receive estimates and information in regard to electrical equipments for coal mines, etc.

ELECTRIC HEADLIGHTS. It is reported by the Railroad Gazette that about 200 electric headlights are in use on eight roads, chiefly for passenger traffic, and with very satisfactory results over oil.

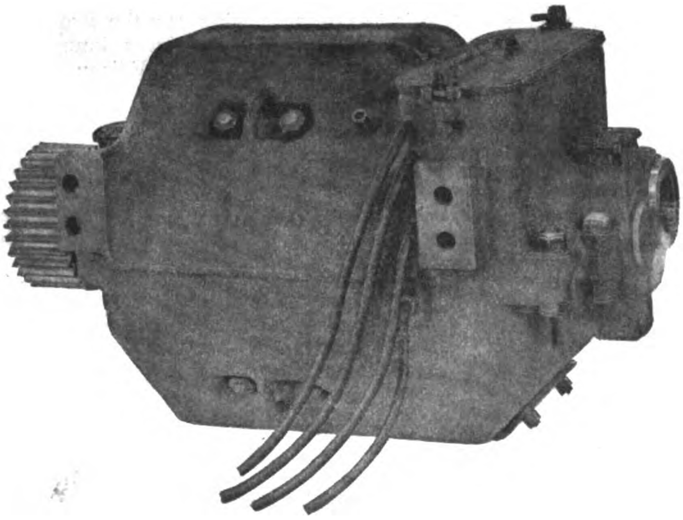
A FIELD TELEGRAPH TRAIN with capacity for sixty miles of line, is reported as part of the equipment of the troops who left Tampa for Santiago de Cuba.

ELECTRIC TRANSPORTATION

New General Electric Railway Motor.

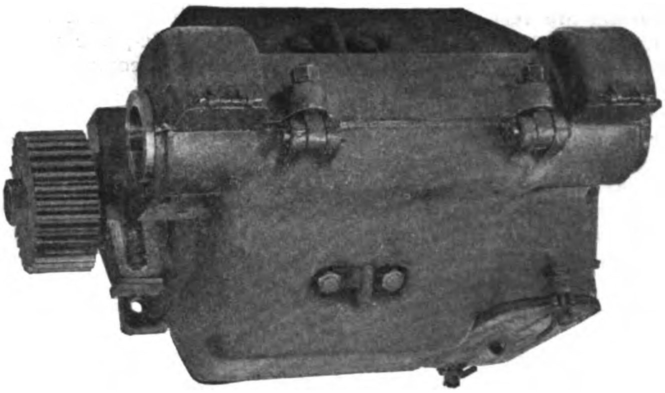
THE General Electric Company announces the development of a railway motor especially adapted for medium heavy railway work, under the designation of the G. E. 51-B. It is the outcome of a series of exhaustive tests on cars and locomotives with heavy trains propelled by electric motors on steam train schedules and the complete and reliable data thus obtained has been used to determine the best form of construction necessary to meet the requirements. This motor has been especially designed for high speed suburban and elevated railway work. It has a capacity of 80 h. p. based on a rating of 75 degs. C. rise in temperature of the windings above that of the surrounding atmosphere after one hour's run at rated load. A double G. E. 51-B motor equipment, with the gear ratio of 2.27 will propel a loaded 20-ton car at a maximum speed of 26 miles per hour on a level track. Higher or lower gear ratios may be used for different speeds; that is, with the speed reduced one-half, the motors will handle a car or train twice the weight.

The frame of the G. E. 51-B is of cast steel, made in two bowl-shaped halves bolted together. It completely protects the working parts of the motor from mechanical injury and the action of water or dust. The upper casting has a large opening to allow of the inspection of the commutator and brush holders, and the replacement of the brushes. This is covered with a dust-proof cover plate easily removed by turning a cam-locking device. A hand hole, also fitted with a weather-proof cover plate, let into the lower frame at the commutator end, facilitates the removal of any foreign substance in the bottom of the motor.



G. E. 51-B RAILWAY MOTOR, FRONT END.

The motor has four laminated pole-pieces with projections supporting the coils which are slipped over them. They are secured by bolts passing through the frame and fastened with nuts on the outside. The bearings have been given ample proportions to insure good lubrication and long life. The upper support of the linings of the armature bearing is part of the upper half of the motor frame; the lower support is a cap bolted to the upper support. The armature can thus be held in the upper half of the motor, while the lower half only is lowered. To remove the armature it may be lowered with the lower half. The cored recess between the inner ends of the lining and the motor frame is occupied by a combination thrust collar and oiled guard, an open space at the bottom being left to give free outlet to oil or grease. With this construction it is impossible for oil or grease to work its way into the motor or come into contact with the windings. The upper supports of the linings are provided with large grease boxes, and the lower are cored, leaving a recess for the oil. Felt wicks or wipers come in contact with the shaft through openings in the lining, and convey a continuous supply of oil to it. The linings of the armature bearings are cylindrical in form, made of cast iron and babbitted, and are held in place by dowels in the lower support. The axle bearing linings are held in place by the upper and lower halves of the frame, extending back and enveloping the car axle. They are made of composite bearing metal lubricated by oily waste held in an oil well and pressed against the outside of the axle by a leaf spring. The dimensions of the armature bearing are—commutator end, 6¾ by 3 inches; pinion end, 9½ inches by 3¼ inches. The axle bearings are 9 inches long with diameter corresponding to the size of the axle.

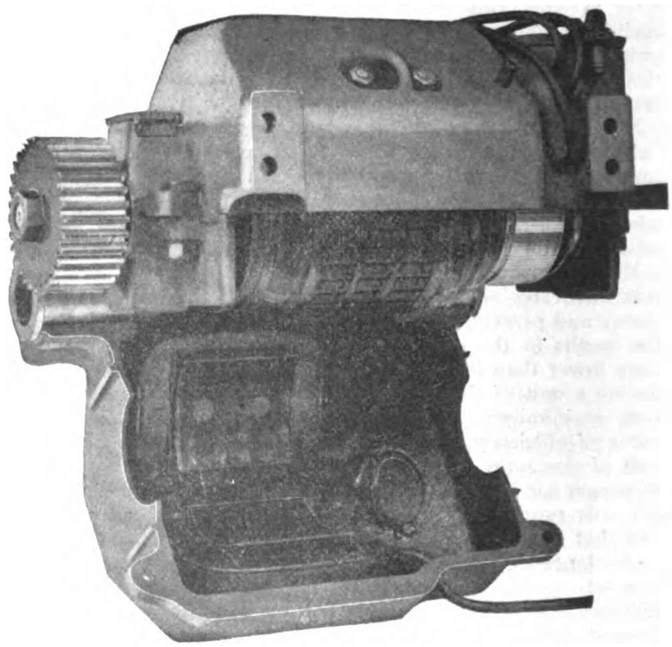


G. E. 51-B RAILWAY MOTOR, REAR END.

The field coils are of copper ribbon wound on metal spools and insulated between turns with asbestos. The coils are thoroughly insulated from spools with specially prepared mica, canvas cloth and press board. After the windings are in place, the canvas is brought over and sewed, completely enclosing and protecting the coil. The whole is then given a heavy coating of weather-proof insulating compound.

For convenience in car wiring and to facilitate opening of the motors, the connections between the upper and lower fields are made on the outside of the motor and both field and armature leads are brought out at the front.

The armature is of the iron-clad, hollow core type, 16 inches in diameter and 10½ inches long. The core is built up of well annealed laminations provided with ventilating ducts, as in the armature of the G. E. railway generators, the laminations being assembled directly on the shaft and not on a separate spider. The core has 37 slots, each containing 3 insulated coils laid together in one compact unit. This gives the armature 37 sets of coils with 111 leads, corresponding to the number of bars in the commutator. All coils are formed and insulated before application to the core, the small number facilitating repairs, while the method of grouping them permits the use of substantial insulation. This is of the highest grade, and



G. E. 51-B RAILWAY MOTOR, LOWER FRAME DROPPED, ARMATURE IN POSITION.

shipment of armatures poorly insulated is prevented by giving each a thorough test with 2,500 volts alternating.

The pinion is made of cast steel with machine cut teeth, and bored for a taper fit on the armature shaft. Both gears and pinions are made at the General Electric Company's gear plant at Lynn.

The commutator is 11⅝ inches in diameter with 111 segments built up with alternating layers of mica insulation and securely clamped on a malleable iron shell. The segments are of the best hard drawn copper 6⅛ inches long, with a wearing depth of 1 inch. The mica cone insulations used in assembling the commutator are built up and compressed into molds, making them hard and compact, and the mica between the segments is especially selected with a view of giving it a degree of hardenss that will make it wear evenly with the copper segments. To insure perfect insulation every commutator is tested with 500 volts direct current between adjacent segments, and 5,000 volts alternating between the segments and the shell.

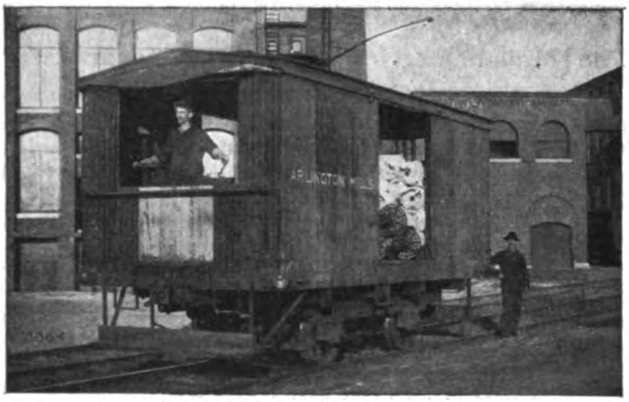
The brush holders are of cast brass and each is arranged to hold two carbon brushes which slide in finished ways and are pressed against the commutator by independent pressure fingers, giving a uniform pressure throughout the whole working length of the brushes. The brush holders are off-set ¼ inch to prevent the wearing of grooves in the commutator and are clamped to a well seasoned hardwood yoke filled with moisture-proof compound bolted to the top magnet frame and easily removable through the opening over the commutator. Mounted on 33-inch wheels, the clearance between the bottom of the frame and rails is 3 inches. That between the bottom of the gear case and rail is 4 inches.

Electric Yard Locomotive, Arlington Mills, Mass.

A STRIKING instance of economy in actual money and elimination of trouble and delay induced by supplanting a steam haulage service with electric traction is afforded by the installation recently made by the General Electric Company for the Arlington Mills, Lawrence, Mass. These mills have about two miles of track running from the main line of the Boston and Maine Railroad into the yards and throwing off spurs into the alleys between the different buildings. Previous to the change to electrical service, the haulage of the entire output of the mills to the main line, the haulage of the material from building to building, as well as the necessary switching about the yards, was done by a steam locomotive rented from the railroad. For this service the Arlington which they took into serious consideration. As every case, in which electric traction has been adopted in factories, showed an improved service, as well as an actual money economy, electricity as a motive power was decided upon.

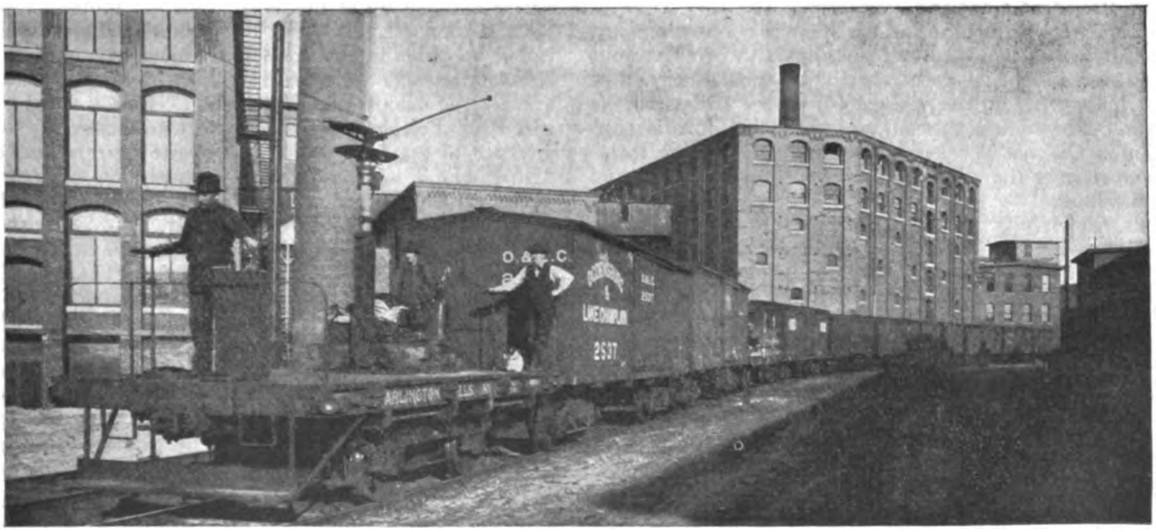
The electrical installation consists of a small generating plant and two electric locomotives, one of the box type and the other a platform car. The generating plant consists of a standard G. E. 75 k. w., 500 volt railway generator driven by belt from an Armington and Sims high speed engine. The generator readily answers all calls upon it, with absolutely no heating or sparking, although it is occasionally subjected to very heavy overloads when both cars are handling a train of more than the usual number of loaded cars.

The box car locomotive used for hauling material about the



GENERAL ELECTRIC BOX CAR LOCOMOTIVE, ARLINGTON MILLS.

yards is equipped with two G. E. 800-27 h. p. motors and series parallel controllers. The platform locomotive is used to haul trains of loaded cars from the yards to the main line, and empties from the line to the mill tracks, and to do all the drilling in the yards. The equipment of this locomotive consists of two 50 h. p. G. E. 1,200 motors with the necessary series parallel controllers. In hauling heavy trains it is assisted by the box car locomotive. Together they are able to handle trains of 30 to 40 empties, or 12 to 14 loaded cars, with comparative ease and celerity. To give the necessary adhesion to the more powerful locomotive to



G. E. PLATFORM LOCOMOTIVE HAULING A TRAIN, ARLINGTON MILLS.

Mills paid an annual rental of several thousand dollars, and were, moreover, frequently put to great inconvenience and delay on account of the unavailability at times of any locomotive.

The successful results obtained with electric factory locomotives by other mills, in New England, notably at Whitinsville, Mass., and Taftville, Conn., attracted the attention of the managers of the Arlington Mills to the question of electric haulage

enable it to handle heavy loads, about six tons extra is placed on the platform.

Perhaps the most interesting feature is the comparison between the cost of the electric plant and the expense formerly entailed by the use of the superseded steam locomotive. The cost of the entire electric plant was very little in excess of one year's rental of the steam locomotive. No more men are employed

about the electric locomotive, the labor cost has not risen and the consumption of coal is scarcely felt on the main plant. Furthermore, the plant being always ready, cars may be shifted at any time during the day or night.

The new system is thus both economical and advantageous, and the appreciation of the Arlington Mills is, perhaps, best shown by the fact that a second platform locomotive is shortly to be added to this haulage plant.

Society & Club Notes

The Midsummer Meeting of the Northwestern Electrical Association.

THE starting of the "Northwest" from Chicago for Milwaukee and other lake ports, for the midsummer convention of the Northwestern Electrical Association was noted in The Electrical Engineer last week.

After leaving Milwaukee on Friday a direct route was taken for Mackinac Island, which it was hoped would be reached in time to allow of a drive. But during the night a heavy fog arose which compelled slowing down, and as a consequence the island was not reached until 1 o'clock on Saturday, and a stop of only fifteen minutes was made there. The sail through the Mackinaw Straits was greatly enjoyed by all.

At about 8:30 p. m. Sault Ste. Marie was reached. A tug bearing the Reception Committee met the "Northwest," and amid a great blowing of whistles the big ship stopped at the entrance to the long St. Mary's lock on the American side. Under the guidance of the Reception Committee and citizens, the Association was escorted beneath a triumphal arch erected in honor of the visitors and bearing the motto, "Welcome" in incandescent lamps. Thence the way was led to the New Iroquois Hotel, where in the large hall the Association was formally welcomed by Mayor Kelleher.

Mr. Francis H. Clergue, vice-president of the Lake Superior Power Co., then delivered a most instructive address on the growing industries and the prospects of Sault Ste. Marie. Various other local speakers followed.

Prof. I. Fujioka, of Tokio, Japan, also addressed the assembly, as did Dr. Elisha Gray, and the Association's thanks were expressed by President Copeland.

The members were up bright and early on the following day, Sunday, and in carriages placed at their disposal visited various points of interest. The first point visited was Fort Brady, now all but deserted, owing to the withdrawal of the troops to the scene of war. Descending the hill on which the fort is situated, the Union Carbide Works were visited. There the members were shown over the works by Mr. W. R. Kenan, Jr., and Mr. H. Von Schon.

The works, which are only temporary, contain four carbide furnaces designed by Mr. W. S. Horry. These are of the continuous type and produce about four tons of carbide per day of twenty-four hours. The furnace consists of an iron cylinder or drum, into which the mixture of powdered coke and lime is shoveled, and into which the carbon electrodes are inserted, the iron drum forming the other electrode. As the carbide is formed the drum is slowly revolved, and new charges are added. The finished carbide drops out at the other end. These furnaces operate continuously and produce about 9 pounds of high grade carbide per day per electrical h. p. We understand that the Horry carbide furnaces will shortly be introduced at the Niagara Carbide works, the two companies having recently been consolidated. At the present time only 2,000 h. p. is being employed in making carbide at Sault Ste. Marie, but this will be shortly increased to 20,000 h. p. in the new works to be erected near the present ones. The power is now transmitted across from the Canadian side, but in connection with the new works the water power will be developed on the American side and the generators direct connected to the water wheels at the new carbide works.

Crossing the Sault the visitors inspected the new Canadian canal and locks operated by electric motors, as well as the adjoining pulp mills owned by the Lake Superior Power Co., the party being under the guidance of the genial Mr. Francis H. Clergue, vice-president of the company. After passing through the mills the party repaired to the "Block House," Mr. Clergue's residence. This is a relic of the old trading post days, but has been transformed, in its internal arrangements, into magnificent bachelor apartments. The party was regaled with a sumptuous lunch, Mr. Clergue making a most charming host. It was no wonder that the company long overstayed the allotted time, and did not get back to the "Northwest" until after two o'clock. After cheers for Mr. Clergue and the "Soo," the steamer pointed its nose toward Houghton, Mich. In the evening a concert was given on board in which the members of the party contributed vocal and instrumental music and recitations.

Every one was up at 6 on Monday morning, the ship having arrived at Hancock, Mich. At 7:30 a special train took the party to the crushers and smelters of the Calumet and Hecla and Tamarack copper mines. All the departments of these admirable establishments were visited under the guidance of the officers and staff of the company, and Mr. James R. Dee, of the Houghton Electric Light Co. Here the visitors stocked themselves with many beautiful specimens of copper ore.

Boarding the train again, the party was taken up to the Calumet mines, about five miles distant. Here the various shaft and compressor houses were visited containing the magnificent hoisting engines, designed by Mr. E. D. Leavitt, Jr., whose great pumping engines at the crushers below had been previously inspected. A sumptuous lunch was then partaken of at the Calumet armory and after visiting some other points of interest the party returned by train, after passing a hearty vote to the Calumet & Hecla Company. As the party boarded ship each one was presented with a souvenir in the shape of a miniature copper ingot.

At 4 p. m. the lines were cast off and, after passing through the Portage Canal, the "Northwest" headed directly for Duluth.

In the evening the Association met in the ladies' saloon and listened to the papers of Mr. A. J. Wurts on "Lightning Arresters," Mr. Snow on "Forced Draft" and Mr. Dow on the "Purification of Boiler Water."

The members were pretty well tired out by this time, but, welcome though rest would have been, it was willingly postponed in order to witness a magnificent display of the aurora borealis, which many watched for a long time.

Tuesday morning found the party at Duluth. Disembarking from the "Northwest," the party took boat for West Superior and put up at the West Superior Hotel. After breakfast electric cars were taken back to Duluth, where the meeting was called to order in the council chamber at the City Hall. The Association was welcomed by Mayor Triaelson.

After the discussions, President Copeland called on Dr. Gray and Prof. Fujioka, who made short addresses.

Votes of thanks were passed to the officers and crew of the "Northwest," who had done so much for the comfort of the party; to the Mayor and citizens of Duluth and of Sault Ste. Marie, and last, but not least, to Mr. J. M. Hill and the members of his committee, who had arranged the trip and carried out the splendid programme provided. Too much, indeed, cannot be said of the ceaseless care and trouble which these gentlemen took to make the trip enjoyable for each individual member, in testimony of which Mr. Hill was presented with a handsome souvenir by the members of the party.

On Tuesday afternoon the citizens of Duluth tendered to the Association a drive about the city and over the splendid boulevard, giving an excellent opportunity of noting the substantial character of the town and the beauty of its surroundings. Later the party was given a boat ride, which afforded another opportunity of studying the shipping facilities of the "Zenith City of the Unsalted Seas."

In the evening a banquet was given at the West Superior Hotel, tendered by the citizens of West Superior. This active city, lying just across the bay from Duluth, is a most prosperous community and is destined to share with its sister city in the undoubted great future progress.

Altogether the midsummer excursion meeting of the Northwestern Electrical Association was most happily conceived and carried out from beginning to end. There was not the slightest mishap to mar the pleasure of the trip, and the good-fellowship

met with on every hand gave the whole affair the character of a family gathering with all that this implies. It is safe to say that the recollection of the trip will never fade from the memory of those who participated in it. We can only say that we are sorry for those who missed it.

The Independent Telephone Association of the U. S. A.

The annual meeting of The Independent Telephone Association of the United States of America will be held at the Palmer House, Chicago, June 30 and July 1 and 2. The meeting will be simply a business meeting of the members, but anyone interested in independent telephony can obtain membership at the meeting and be entitled to admission to the sessions. The press will be furnished such information as can be made public by a committee appointed for that purpose.

American Institute of Electrical Engineers.

The Institute will hold its fifteenth general meeting at the Millard Hotel, Omaha, Neb., beginning Monday, June 27, at 10 a. m., with daily sessions until Thursday. President Kennelly will deliver an inaugural address, and some sixteen papers will be read. The exposition will be one of the features of the meeting, which should draw out a good attendance of Western members.

Railway Telegraph Superintendents.

The National Association of Railway Telegraph Superintendents met at Omaha on June 15 and elected the following officers: President, W. W. Ryder, of the Chicago, Burlington & Quincy, Chicago; vice-president, L. B. Foley, of the Delaware, Lackawanna & Western, New York; secretary and treasurer, P. W. Drew, of the Wisconsin Central, Milwaukee.

A Creditable Canadian Electrical Journal.

Apropos of the eighth annual convention of the Canadian Electrical Association, to be held in Montreal on the 28th, 29th and 30th inst., the publisher of the Canadian Electrical News of Toronto has issued a specially interesting number for June, the contents of which serve to illustrate the rapid development of electricity in Canada. Besides the electrical features of Montreal (including portraits of the local committee of the Electrical Association convention), other articles worthy of mention are: "The Mooteu Wireless Telegraphs," by D. H. Keely, superintendent Dominion telegraph system; "The Cataract Power Company's Works," in course of construction (illustrated); description of C. P. R. copper wire from Montreal to Vancouver, B. C., with portraits of officials and superintendents of construction; map showing long-distance lines and offices of the Bell Telephone Company. Altogether, it is a valuable number for those engaged in electrical pursuits.

THE N. A. OF S. E. of Greater New York, has opened a bureau of employment for members of the association at room 39, Bible House, Third avenue and Twenty-eighth street. It is in charge of Mr. J. H. Monckton, as manager. The bureau will be glad at any time to furnish reliable men for stationary engineers' positions.

MARRIED

Gill—Stewart.

William B. Gill, well known as the superintendent of the Philadelphia division of the Western Union Telegraph Company, was married recently to Miss Helen Stewart at the residence of the bride's mother in that city. The wedding was a very quiet one, only the immediate family being present. The ceremony was performed by Rev. Joseph Wilson Cochran, of the Northminster Presbyterian Church. Immediately after the ceremony Mr. and Mrs. Gill left for a wedding trip. Upon their return they will reside at Mr. Gill's country house at Cheltenham.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued June 14, 1898.

Alarms and Signals:—

LETTER BOX. M. J. Wine and C. A. Thompson, Washington, D. C., 605,592. Filed April 17, 1897. Provides an indicator situated at a point convenient to the carrier to indicate whether there is any mail in the box.

SELECTOR SIGNALING SYSTEM. T. C. Drake, Malta, Ohio, 605,688. Filed Sept. 17, 1897. Details of construction.

AUTOMATIC ELECTRIC FIRE ALARM. H. A. Olsson, Quincy, Mass., 605,795. Filed June 17, 1897. Constructed to automatically sound an alarm to indicate in which of the rooms of the house the fire is started.

ELECTRIC RAILWAY SIGNAL. C. L. Renrew, East Windsor, Conn., 605,798. Filed March 2, 1897. Designed to warn the engineer upon one railway vehicle of the presence of another vehicle or obstruction upon the same track.

Batteries, Secondary:—

SECONDARY BATTERY. C. Brault, Paris, France, 605,695. Filed Dec. 28, 1896. Comprises a body of active material, an enclosing fabric of asbestos, an outer covering of perforated neutral material and cross rods, lying in openings in the active material, their ends being connected to the neutral plates by a solvent of the material of which the plates are composed.

Conductors, Conduits and Insulators:—

STRAIN INSULATOR. L. McCarthy, Boston, Mass., 605,741. Filed Jan. 18, 1898. Comprises metallic portions separated from each other by interposed insulating material, a case having inwardly projecting flange, a sleeve and bolt.

Distribution:—

SYSTEM OF ELECTRICAL DISTRIBUTION. C. P. Steinmetz, Schenectady, N. Y., 605,525. Filed Jan. 28, 1895. Comprises a dynamo electric machine, having out-of-phase coils connected to three collector rings, and the remaining terminal of one coil connected to an intermediate point in the second coil, and a fourth collector ring likewise connected to the intermediate point in the last named coil.

SYSTEM OF ELECTRICAL DISTRIBUTION. C. P. Steinmetz, Schenectady, N. Y., 605,526. Filed June 17, 1897. Combines a generator having a main coil, and a supplemental coil at an angle thereto connected at one end to an intermediate point in the main coil, with a three-wire distributing system fed from the main coil, and a multiphase translating device from both coils.

Electro-Metallurgy:—

ORE STAMP. D. M. Smyth, Pasadena, Cal., 605,615. Filed June 9, 1897. Combines two stamps and the electromagnets for actuating the same with circuit connections and a switch that is changed by the upward movements of the stamps alternately, for energizing the magnets and raising one stamp and accelerating the fall of the other.

Electro-Therapeutics:—

ENDOSCOPIC INSTRUMENT. T. S. Pitt, Boston, Mass., 605,652. Filed June 1, 1897. A detachable light holder for use on an endoscopic instrument comprising a concavo-convex body portion for receiving the incandescent light and having an extended shank with bayonet slots for attaching it in place, and a removable sliding cover formed with upwardly-turned reflectors.

Lamps and Appurtenances:—

INCANDESCENT ELECTRIC LAMP. O. H. Michaelson, Charleston, W. Va., 605,498. Filed July 17, 1897. The globe and its base may be separated for the purpose of cleaning or replacing a broken filament.

ELECTRIC ARC LAMP. D. Higham, Boston, Mass., 605,714. Filed Oct. 26, 1897. Designed for direct-current constant-potential circuits, having two or more sets of electrodes connected in series and magnetic means for controlling the current passing, in combination with means for momentarily extinguishing the current by opening the circuit at suitably frequent intervals.

Measurement:

ELECTRIC RECORDING INSTRUMENT. C. L. Jaeger, Maywood, N. J., 605,548. Filed Aug. 7, 1897. Speed indicator and recorder.

TELEPHONE RECEIVER. P. C. Burns, Chicago, Ill., 605,594. Filed Nov. 20, 1897. Comprises a permanent magnet and its accessories, an insulating disc secured to the heel thereof, a sleeve adapted to slip over the disc, a screw threaded collar, an adjustable ring, stop screws, a diaphragm and a diaphragm cup.

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 605,665. Filed Aug. 6, 1897. Comprises an annular armature, coils exterior to the armature, coils within the armature, circuit connections for energizing the outer and inner coils, a magnetic core having part of its poles enclosed by the inner coils, and closed circuits on the other poles of the core.

APPARATUS FOR SUPPLYING OR MEASURING CURRENTS OF ELECTRICITY. W. D. Watson and T. Humphreys, Rochdale, England, 605,765. Filed Dec. 28, 1897. Comprises a clock-work and its adjuncts, with mechanism for cutting off the current supply and means actuated by the key of the clock-work when applied thereto for working the cut-out.

Miscellaneous:—

ELECTRIC ELEVATOR. H. Cochrane, Chicago, Ill., 605,598. Filed April 19, 1897. A brake for elevators employing compound wound motors.

ELECTRICALLY DRIVEN AND MOVED PLOW. E. Dallmann, Neusalz, Germany, 605,631. Filed Oct. 9, 1897. Details of construction.

INSULATING ELECTRODES FOR ELECTRIC GAS LIGHTING BURNERS. A. L. Bogart, Jamaica, N. Y., 605,661. Filed May 5, 1897. Designed for use on Welsbach burners and combines one of the electrodes formed of a metal wire with an insulating shield through which the wire is threaded.

APPARATUS FOR COOLING AND PURIFYING LIQUIDS. O. W. Swift, New Haven, Conn., 605,685. Filed July 16, 1897. The liquid is sprayed and simultaneously subjected to an electric current.

Railways and Appliances:—

ELECTRIC RAILWAY. A. J. Moxham, Lorain, Ohio, 605,508. Filed Nov. 18, 1897. Embodies a bared sectional conductor in series with one side of the circuit through a current conveyor which is closed by the passing vehicle, and track rails connected to the opposite side of the circuit, contacts placed adjacently to crossing track rails and in circuit with the source of supply through a hand operating device.

ELECTRIC RAILWAY. C. H. Davis, New York, 605,663. Filed Nov. 2, 1897. The line is divided into insulated divisions, a signal device is associated with each division and constructed to exhibit a danger signal and a safety signal, and means controlled by the signal device for interrupting electrical circuit through the associated line division when the danger signal of that device is exhibited.

COMBINED TRAIN ARRESTING AND SIGNALING MECHANISM FOR ELECTRIC RAILWAYS. C. H. Davis, New York, 605,664. Filed Nov. 9, 1897. Similar to above.

MOUNTING FOR ELECTRIC MOTORS. E. B. W. Reichel and F. W. V. Stein, Berlin, Germany, 605,679. Filed Jan. 27, 1898. Consists of a spring carriage mounted upon the truck of the vehicle, a supporting rod carried by the spring carriage whereon the motors are mounted upon either side of the spring carriage, a non-rigid mounting connecting the supporting rod and motors and a supplemental connecting part uniting the motors.

TROLLEY WHEEL. A. F. Humphrey, Allegheny, Pa., 605,716. Filed Dec. 9, 1897. Employs two spring-actuated arms which extend over the trolley wheel and prevent the wheel from leaving the wire.

TROLLEY POLE. J. N. Prisk, Johnstown, Pa., 605,796. Filed Feb. 8, 1897. Means for retaining the trolley in contact with the wire either from above or below.

ELECTRIC RAILWAY SYSTEM. H. A. Chase, Boston, Mass., 605,814. Filed Feb. 7, 1891. Underground conduit system.

ELECTRIC RAILWAY. R. M. Hunter, Philadelphia, Pa., 605,824. Filed Dec. 14, 1897. Means for controlling the speed of an electric train of cars as distinguished from the control of an individual car.

Telephones:—

CARBON TRANSMITTER. G. W. Goss, Kokomo, Ind., 605,575. Filed April 20, 1897. Provides a chamber to receive the powdered carbon, and an agitating device separate from the carbon holder and arranged within the chamber for agitating the powdered carbon independently of any movement of the carbon holder.

TELEPHONE CIRCUIT AND APPARATUS. M. G. Kellogg, Chicago, Ill., 605,580. Filed March 23, 1897. Multiplex system of telephony.

AUTOMATIC APPARATUS FOR TELEPHONE SWITCHBOARDS. J. H. West, Berlin, Germany, 605,659. Filed July 8, 1896. Details of construction.

TELEPHONE SWITCHBOARD SYSTEM. F. C. Hughes, Detroit, Mich., 605,670. Filed July 3, 1897. Details of construction.

CORD WEIGHT FOR TELEPHONE SWITCHBOARDS. F. C. Hughes, Detroit, Mich., 605,671. Filed Sept. 27, 1897. Comprises a narrow confining way composed of smooth parallel plates, a thin heavy disc located in the way whose opposed faces are smooth and stand contiguous to the walls, and a cord passing around the arc of the disc in the way and supporting the disc.

TELEPHONE TRANSMITTER. W. E. Sundberg, Worcester, Mass., 605,832. Filed Sept. 28, 1897. Comprises two carbon contact plates, one of the carbon contact plates being adjustably mounted in the transmitter casing and the other contact plate being carried by a diaphragm arranged to be vibrated by the sound waves acting thereon through the ordinary mouthpiece.

REPORTS OF COMPANIES

The Proposition to Reduce General Electric Stock.

Samuel Carr, Thomas L. Livermore and Edward F. Atkins, who, in January, 1896, were appointed a committee by the holders of more than one-half of the preferred stock of the General Electric Company, have issued a circular in Boston to the preferred stockholders relative to the subject of a dividend. They say that they have on several occasions urged the declaration of a dividend on the preferred stock, but have been met with the reply that the laws of New York prohibited such action, as the value of the company's assets was less than the amount fixed as the company's capital stock, $34,712,000. The committee's circular continues, as follows:

The report of the company of January 31, 1898, shows that the profits of the business for the year were at least $1,481,852—equal to 7 per cent. of the preferred stock and nearly 3.88 per cent. of the common stock. The report also shows that the value of the stocks and bonds on hand exceeds the outstanding bonds of the company by $1,455,872, and that cash and notes and accounts receivable equal $5,963,175, as against accounts and interest payable of only $313,525.

This sound state of affairs seems to remove all ground for further withholding the earnings of the company from shareholders. To remove what directors regard as legal obstacles in the way of resuming dividend payments, it has been suggested that the nominal value of the capital stock should, by vote of shareholders be reduced so as not to exceed the value of the assets of the company; and to this end a reduction of 50 per cent. of the par value of the shares has been suggested, together with payment of the accumulated dividends on the preferred shares to date of reduction at the rate of 7 per cent. on the present par value of $100 per share.

Eminent counsel advise the directors that as a legal result of this reduction the holders of preferred shares would be entitled to dividends out of future earnings of 7 per cent. on $50 per share only, while holders of the common shares would be entitled to all the remaining earnings. This would, for the future, reduce the dividend on preferred shares one-half, while it would leave the common shareholders in a better position than their present one.

The company's assets, the circular continues, amount to at least 72 per cent. of the par value of all the shares; and for this reason the committee has declined to recommend a reduction to any amount below $72 a share. The proposition to reduce the par value of the shares to $50 is soon to be submitted to a meeting of stockholders, who can by a two-thirds vote carry it unless restrained by legal process. The committee seeks authorization to oppose this project at the meeting and in the courts, and to that end asks for the deposit of certificates of shares assigned to the American Loan and Trust Company, for which it will issue negotiable receipts.

Erie Telephone Annual Meeting.

At the annual meeting of the Erie Telegraph and Telephone Company, Charles J. Glidden in the chair, held in this city last week, the following were elected directors: Charles E. Adams, Charles J. Glidden, J. W. C. Pickering, Asa C. Russell, Levi Sprague and James H. Mills, of Lowell, Mass.; Wesley A. Gove, David S. Greenough and Charles S. Tuckerman, of Boston, Mass.; Harvey A. Whiting, of Wilton, N. H.; Henry D. W. Burt and H. Fred Stevens, of New York. Mr. Mills succeeds Abner S. Adams, of Lowell, deceased. The Board of Directors organized by the election of the following officers: President, Charles J. Glidden; secretary, George B. Perham; treasurer, Charles A. Grant; general manager, James P. McKinstry. The annual meeting of the Southwestern Telegraph and Telephone Company was held at the same place, and officers elected as above, with the exception of Messrs. Burt and Stevens, of New York, and with the addition of Thomas Sherwin, of Boston, and David B. Parker, of Buffalo, representing the American Bell interests in the company. The company now has 26,570 subscribers.

Annual Meeting of Siemens-Halske Elec. Co.

The annual meeting of the stockholders of the Siemens & Halske Electric Company of America was held on June 16 at their offices, Monadnock Block, Chicago. Nearly the entire capital of the company was represented at the meeting, and the following gentlemen were elected directors of the company: Chas. T. Yerkes, Martin Maloney, Jno. R. Bartlett, R. Suydam Grant, Chas. E. Yerkes, E. A. Moore, B. W. Grist, Howland Coit, W. L. Elkins, Jr.

The new board of directors was organized, and the following gentlemen were elected officers of the company: Chas. E. Yerkes, president; W. T. Block, secretary and treasurer; C. F. Marlow, asst. secretary and asst. treasurer; B. W. Grist, general manager. The following gentlemen compose the executive committee: Martin Maloney, Chas. E. Yerkes, J. R. Bartlett.

Consolidation of Cutler-Hammer and American Rheostat Companies.

An important combination in the rheostat business has just been consummated by the consolidation of The Cutler-Hammer Mfg. Co., of Chicago, with the American Rheostat Co., of Milwaukee, both companies being well and favorably known to the electrical trade. The business will be carried on under the name of The Cutler-Hammer Mfg. Co. at 70-80 West Jackson street, Chicago. The capital stock of the combined company has been increased to $75,000, and a large proportion of this increase has been invested in new machinery. With its increased manufacturing facilities and larger capitalization the company will be able to take care of its rapidly increasing business in a prompt and satisfactory manner. The officers of the new company are as follows: F. R. Bacon, president; F. L. Pierce, vice-president; J. G. Hickcox, secretary and treasurer; H. H. Cutler, electrical engineer and general manager.

TRADE NOTES & NOVELTIES

Manufacturers and Dealers in Electrical Supplies in Pittsburg—Notes From the Field.

BY C. B. FAIRCHILD.

THE WASHINGTON CARBON COMPANY.

AS the name implies, this firm are manufacturers and dealers in carbons for electrical purposes, including arc light pencils, generator and motor brushes, battery carbons, and large carbons for electrolytic purposes. The works are located at Washington, Pa., thirty miles from Pittsburg, and occupy a tract of about three acres, which is covered with numerous buildings of corrugated iron, usually one story in height. They are conveniently located to each other, and are thoroughly equipped with the necessary appliances for receiving the crude material and passing it through the various processes until it reaches the storage and shipping department, from which the products go to all the world, competing successfully with the reputed high grade products of the old country.

The works really consist of two factories, in which different processes are employed for forming the carbon, one known as the moulding process, the other a pressed process. The products are also graded, and the higher grades are produced from what is known as lamp black carbon, and in the making of which certain trade secrets are employed which we are not permitted to describe. While in the manufacture of the ordinary grades there are no secrets, and the biography of a carbon pencil becomes very interesting, although it grows to its marketable shape through an atmosphere laden with its own black dust and a temperature that is exceedingly trying to those who direct the operations.

The material from which carbons are made is known as coke, comes in large chunks, and is delivered by cars directly into the works. It is the residium of petroleum oil stills, and is purchased directly from oil refineries. It is a black, porous material, and has about half the specific gravity of the Connellsville coke. The material is first ground in an ordinary bark mill, to what is known as pea size, and is then elevated by belt conveyers to large storage bins on the second floor. From this it is drawn and shoveled into the calcining furnaces or retorts, which are made of fire brick. These are filled with the material and are fired by means of natural gas, the burners entering at intervals through the front wall. The door is tightly closed, so that the material burns in its own gas, and by this process all the volatile matter is consumed, and the mass settles down to about eighteen inches in thickness, being then 99 per cent. pure carbon. It is then removed while still hot in iron barrows and placed in the cooling bins, and when cool it is again elevated and ground in an ordinary burr stone mill the same as flour, and in passing from this mill, is bolted through silk cloth into four grades. Each grade is then weighed and mixed with a certain portion of pitch, known as binding material, which by itself is a product of coal tar distillation, and which has already been crushed as described for the carbon. After mixing it is placed in a closed revolving heater or mixer, in which the binding material is thoroughly incorporated with the powdered carbon at a temperature of about 200 degrees. From the mixer the material is elevated to a cooling room which is about thirty feet square, where it remains until thoroughly cool, when it is again ground, this time in a centrifugal mill, consisting of two discs set edgeways, and which are revolved in opposite directions, the material being fed through a hopper at the top. By this means it is reduced to a fine powder, when it is again bolted in revolving sieves, and is now ready for moulding into shape. This process is performed by men occupying booths or pockets, of which there are twenty-eight arranged on either side of a line of three endless conveyors, seventy feet in length, and each about eighteen inches wide. The middle conveyor travels in an opposite direction from the others, and twice as fast, and in the direction of two hydraulic presses, located at the end of the conveyor. The bin in each moulder's booth is filled at night with a sufficient supply of material to last him for a day. The moulds are of metal, made in two parts, and contain grooves for from twelve to eighteen pencils, depending upon the diameter of each. Each moulder carefully weighs out sufficient material (which is now a fine powder), to fill one of the flasks, which are kept hot by means of natural gas jets that are burning under the grated surface of the table. One half of the flask being filled and smoothed off with a straight edge, the other half, somewhat smaller, is placed on top of the powder, and slightly pressed down by hand. The mould when filled is slid across the first conveyor to the middle one, by which it is carried to the presses, where two attendants move it to the right or left, upon the hydraulic press plungers, which are thirteen inches in diameter, and which are started by a foot lever, and when the pressure as indicated by a gauge comes up to 350 tons, it is automatically cut off and the mould released. The attendant places it on one of the returning conveyers, and one is taken off by each moulder in turn, when they remove the pencils which are held together by a thin web of material. These are then placed in racks and removed to the dressing table, where they are broken apart by a wedge-shaped tool that is hit with a light hammer. This work is performed by boys, who become very expert. The pencils are then fed by hand into a dressing machine, in which they are drawn through between two steel discs about six inches in diameter, set at an angle to each other, and which have sharp cutting edges and are revolved slowly, so that the edges are kept true and perfect. By this process the material that composed the web is shaved off, leaving the pencils smooth and cylindrical. The pencils are then packed in trays and are ready for the baking process. This is done in furnaces, of which there are 21 in the first factory. These each have a capacity of from 60,000 to 100,000 pencils. The walls of the furnace are of fire brick, and are arched over with the same material, made in sections, so that they can be readily moved for filling or cleaning. The pencils are carefully piled in layers to the depth of four feet, there being a thin course of black sand between each layer of carbons. Being filled, the top is replaced and jets of natural gas are turned in at the front. The walls are perforated with flues along the upper edge on each side, so that the flames pass over, down the side, and under the mass, bringing it to a uniform heat. The process of baking including the time for packing and cooling, requires about three weeks. The pencils are then removed and placed on racks, by means of large steel-tined forks, like hay forks used by farmers. They are next taken to the sorting room, and are assorted for the purpose of removing the "crooks" from those that are straight. This is done by allowing them to roll one at a time down an inclined plate, set at such an angle to the eye of the operator that he can detect by looking under any unevenness in the pencil. The crooks are removed and are cut into shorter lengths, making from 7 to 10-inch carbons, while the ordinary lengths are from twelve to fourteen inches. From the sorting room some go directly to the packing department, while those that are to be copper plated are taken to the plating department. In this process the pencils are suspended from copper bars being attached by plating snap. These are then immersed in a solution containing copper plates, about four hundred pencils being placed in each vat. The plating process requires about twenty minutes, the electrolytic action being set up by means of a current from two generators, one having a capacity of eight hundred and the other of five hundred amperes. The pencils are then removed to drying racks, and when thoroughly dry are packed for shipment, from five hundred to one thousand being placed in each box, depending upon the size of the pencil.

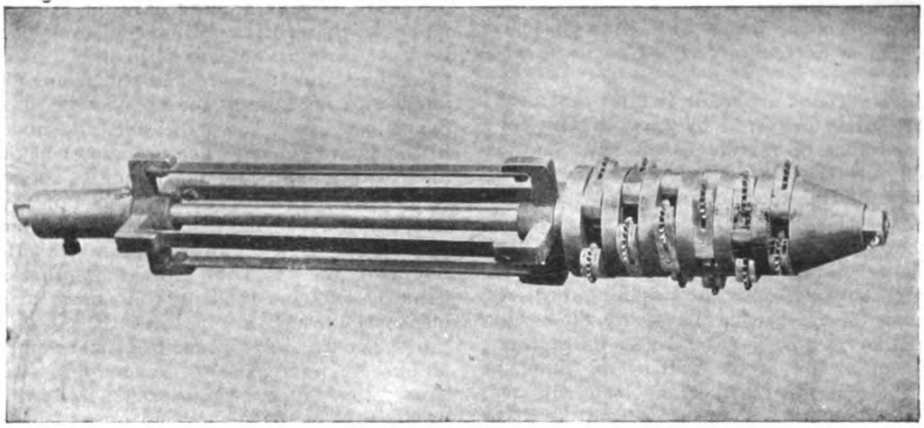
In the second factory, where the pressing process is employed, the material is ground and prepared in about the same manner as described above, when it is pressed by hydraulic power into cylinders 6 by 6 inches. A number of these are then placed within the chamber of one of the large horizontal presses, of which there are four. A brass follower is then inserted, and the plunger of the hydraulic press forces this against the charge with a pressure of 250 tons, forcing the material through a die at the outer end of the cylinder in a continuous rod, and of any size that may be desired, depending upon the die, from one-half inch in diameter up to three inches for cylindrical bars, and four inches square for the larger sizes, and flat bars of all sizes. The bars are then cut up into suitable lengths and are baked in furnaces as before described, when the pencils are pointed on an emery wheel. In these hydraulic machines the cored carbons are also formed.

The power for operating the machinery is derived from two Westinghouse compound engines of 100 horse power and an engine of another type of 50 horse power. The station is equipped with two lighting generators, one for arc, and the other for incandescent light; there is also a machine shop and tool room for making dies and doing general repair work.

The testing department occupies the second floor of the office building, where samples from each of the furnaces are thoroughly tested, both for light and efficiency and for resistance. For testing the length of an arc a small lens is provided, which throws the shadow upon a graduated sheet, and there are several cupboards lined with asbestos with plates of colored glass in the doors for making the various tests in lamps of the durability and character of the ray. Samples of all material when received are carefully subjected to a chemical test and every precaution is used to produce perfect carbons of a high grade for any kind of service.

The Union Boiler Tube Cleaner.

THE users of steam were made glad by the introduction, in 1895, by the Union Boiler Tube Cleaner Company, of a mechanical device that satisfactorily solves the perplexing problem of the removal of scale from the tubes of all boilers of the water tube type. The device illustrated in this connection not only removes the scale, no matter how thick or hard, but in turn so polishes the interior of the tubes by removing even the mill scale, that it makes it impossible for scale to adhere so tenaciously in the future, making subsequent cleaning relatively easy, while it greatly adds to the efficiency of the boilers, by improving the circulation, increasing the radiation, resulting in a saving of fuel. The device, as shown, consists of a conical head, having a taper of about ¾ of an inch, and which is composed of discs, between each pair of which are pivoted three short arms, which carry at their outer end to other wheels or cutters about 1⅛ of an inch in diameter, the arms being set spirally. Back of the tapering head there is a series of guide bars, supported by bearings in which the operating rod revolves. The cone is somewhat smaller than the tube, and being inserted, it is given a rotary motion of about 1,600 revolutions per minute, so that the arms which have a range of from 3-16 to ⅜ of an inch, fly out from centrifugal force, bringing the cutters in contact with the scale on the walls of the tube. The action of the teeth of the cutter wheel is not a scraping or grinding one, but is an impact or vibratory movement, caused by the roughness of the scale, from striking which the arms retreat, after a blow, and immediately return, so that the points of the teeth as they revolve cut into and disintegrate the scale, which is continually flushed out by a stream of water that is fed into the tube by a hose as the process goes on. The scale being removed, the cutter wheels simply revolve on the inner walls of the tube and lose their vibratory motion, so that they have no effect on the tube, except to burnish it, but do not injure or expand thin tubes. The arms, discs and cutters composing the head are made of a high grade of tool steel, and are tempered by a special process, making them very durable. With this machine a man can clean from 20 to 50 tubes a day, depending upon their condition, or whether it is the first or second cleaning.



DEVICE FOR CLEANING WATER TUBES OF BOILERS.

This company manufacture two types of heads, one rigid, the other flexible, the latter designed for boilers having curved tubes, and which is operated by a flexible shaft, the other is straight, and is operated by a rigid shaft. In the process of cleaning a platform about 10 feet long is first erected, the full width of the boiler, and a little below the lower row of tubes. The boiler doors being removed, the tubes are uncapped, both front and back, when to the door hinges brackets are bolted, to which is attached an adjustable cross-bar, which carries the driving head. For cleaning straight tubes, the cleaning head is attached to a straight rod, which is given a rotary motion by means of a driving pulley, through which the rod slides, a sleeve with a key way being provided. By means of a handle on the outer end of the rod the operator can move the head at will back and forth in the tube, without interfering with its rotary motion. The driving pulley is operated by a continuous rope belt, consisting of two or three strands, which is driven from a steam engine, or from an electric or other motor, as the conditions may demand, from 5 to 10 horse power being required. When a rod is fed through the pulley, the handle is removed and a second rod is fastened on with a snap coupling, when the handle is replaced at the end. These rods are made in about 6 feet lengths and may be coupled together sufficient for any length of tube.

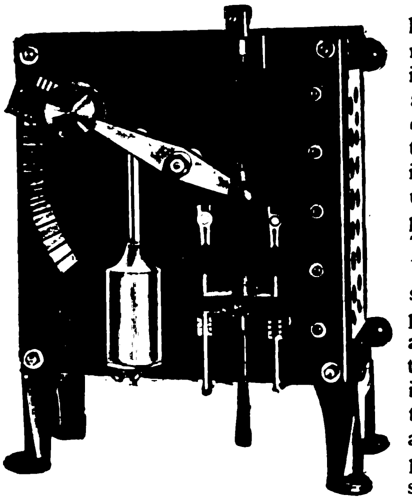
For cleaning curved tubes a flexible head and a flexible shaft are employed. This shaft is composed of solid brass links of peculiar shape; this shaft or chain in turn is enclosed in a closely fitting spirally wound tube, composed of peculiarly shaped wire, flat on the inside, which gives a smooth bore in which the link chain operates. The spirals are also dished on the outside to provide a firm hold for an oil proof rubber tube, by which the shaft is encased, allowing for oil lubrication, but protecting the shaft from the effects of the flushing water, which is led into the tube as described for the straight shaft.

For revolving the shaft, especially the flexible one, the company have recently devised a high-speed, noiseless air motor, which can also be operated by steam. This is a self-contained motor having three trunk pistons, which are attached to the same crank pin, making a very compact machine. Motors of this design of one-half horse power capacity weigh only 26 pounds and contain only 21 parts, and are so designed that when running at a speed of 2,600 revolutions per minute they can be reversed without shutting off the steam. The company contemplate the use of this type of motor, not only for boiler cleaning purposes, but for the propelling of yachts and mechanical vehicles, and for operating small isolated electric light plants, the air to be supplied in seamless tubes under high pressure, the tubes to be refilled and returned when exhausted.

It is the practice of the company to either sell their tube-cleaning device outright, or rent them to steam users by the year, or contract to clean boilers for so much per horse power. In all cases where a sale or lease is effected, an expert is sent to install the device and give instructions as to how it should be used, without charge.

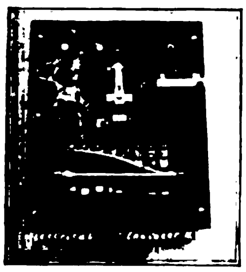
The shops for the manufacture of tube cleaners and motors occupy the fifth floor of the Imperial Power Building, 251 Pennsylvania avenue, Pittsburg, equipped with a complete assortment of metal-working tools. The company's office adjoins the shop.

Gravity Motor Controller of the Electrical Appliance Co., N. Y.



The device represented herewith possesses many meritorious features. It is very simple in design, and durable. Few parts enter into its construction. Particular attention is called by the manufacturers, the Electrical Applance Company, 27 Thames street, New York City, to the absence of numerous complicated operating parts; also to the contacts and the use of a non-conducting device for securing tension, of such design as to take up all the wear possible. Realizing the severity of the service required, they have made adequate provision for it. The controller can be readily attached to belted elevators by making rod connections direct from the belt shifting wheel, or the wheel operated therefrom. This controller can be used for starting an elevator and motor simultaneously and for starting the motor in advance of the elevator, but still retaining the automatic cut-off feature. That is, when the elevator car stops, the motor does also. It can also be arranged for starting and stopping the motor independent of the elevator or other apparatus. These controllers are made in sizes varying from 3 to 50 h. p., and are designed for the control of elevators, motors, pumps, presses, cranes, etc.

Ohio Electric Specialty Mfg. Co.



The Ohio Electric Specialty Manufacturing Company, of Troy, O., manfacturers of "Perfection" all-copper woven wire bronze gauze, and leaf copper brushes, the Rogers commutator lubricant, "Imperial" rheostats, speed regulators and motor starters, have lately received numerous orders for this latter device, which is illustrated herewith. The motor starter, with over-load device, has all the advantages of the company's regular automatic motor starter, besides protecting the motor from overload, short circuit or other causes of damages. The overload device acts in conjunction with the automatic release plate by protecting the armature and commutator against the sudden rush of current due to a short circuit or other cause. It is a complete protection to the motor, and is made for any size, voltage, resistance of field and make of motor. The company are prepared to send on trial any of their goods, which, if not satisfactory, can be returned at their expense. A catalogue illustrating the company's numerous specialties will be sent to anyone upon application.

A Big Walker Generator for Boston.

The Boston Elevated Railway Company has placed an order with the Walker Company, of this city, for the construction of a direct current generator which will be the largest ever built. This monster generator will have a capacity of 4,000 h. p. and will be capable of delivering over 5,000 h. p. for a few hours at a time. The machine will weigh 300,000 pounds, the armature alone weighing over 100,000 pounds. To drive this great machine will require an engine of nearly 5,000 h. p., and the generator armature will be placed directly upon the shaft of the engine.

INVENTORS will discover from Edward P. Thompson's recent circular that his power to maintain the single specialty of soliciting patents for fifteen years is due largely to his being an electrical expert as well as versed and experienced in the law relating to patents.

Locke Victor Insulators.

Mr. Fred M. Locke, of Victor, N. Y., forwards us a copy of his patent, No. 605,109, of June 7, 1898, covering his latest forms of triple petticoat high tension insulator, with a long, central petticoat glazed inwardly, the insulator being of three shells of vitrified china, and then all fused together with the glaze into one homogeneous insulator. Mr. Locke warns that he will protect his rights and that he proposes to collect royalties.

Westinghouse Induction Motors in South Carolina.

The Westinghouse induction motor, known as the type "C" machine, has recently extended its usefulness to a unique field in North Carolina, namely, the operation of fertilizing machinery. The Westinghouse Company has recently supplied the Fries Mfg. Co., of Salem, N. C., with six of these motors, and a number of lightning arresters, high tension transformers, etc., which are to be used for the above purpose, and also for driving a city pumping station, planing mill, machine shop, iron foundry, etc. The choice of Westinghouse motors was made largely on account of their extreme simplicity. They will be operated by workmen entirely unfamiliar with electrical machinery. This is one of the first installations of the character in North Carolina, and is being watched with great interest throughout the State.

C & C Electric Co.

We understand that the C & C Electric Company, of New York, are still getting their usual large number of orders, in spite of the war, and are not complaining at all. Their factory continues to run day and night with a large force of men, as it has done for nearly a year. They are receiving their usual large number of orders for their bipolar dynamos and motors, while their orders for slow speed multipolar generators and motors are still most gratifyingly large. During the last month they have taken some excellent orders for electric lighting and power installations, including not only the machines, but the complete plant. Among these might be mentioned two secured from the American Fisheries Company for complete installations at their establishments at Promised Land, L. I., and Lewes, Del., each of the plants including a 30 k. w. generator, the one at Lewes being a belted machine, and tnat at Promised Land being an engine type, direct connected to an Alfree engine, which the C & C Company is also to furnish. In addition to these, the company took the contract for the wiring, lamps, etc. They are also installing a 100 k. w. direct connected generator and a 175 h. p. Buckeye engine, together with switchboard, etc., in the large establishment of the H. B. Claflin Company, New York. Their Louisville representative, Mr. J. H. Cochran, has taken orders from the Tobacco Warehousing and Trading Company, of Louisville, Ky., and Danville, Va., for complete lighting and power plants for their two establishments located at these places. In each case the installation will consist of two 20 k. w. engine type generators direct connected to Watertown vertical engines, which the company is also furnishing, together with two special slow speed blower combinations, each blower being fitted with a variable speed eight pole 10 h. p. motor with double commutator; also two 24-inch exhaust combinations. The plants will be exact duplicates. The company has also recently received numerous orders for its closed type ironclad motors of various sizes, besides a number of marine generating sets, in which Case engines direct connected to closed type ironclad dynamos will be used. There is still a very active demand for their back-geared ironclad motors and electric hoists, which have met with universal favor.

NEWTOWN, Pa. The Standard Telephone Co. has contracted with A. M. Worstall, of the Witherspoon Building, Philadelphia, for the installation of its system, the apparatus being built by the Pennsylvania Electric Company, of Marietta, Pa. The switchboard capacity is 50 drops, and the rates are $12 for residences and $18 for business offices. The toll line rate is 10 cents for eight miles. Toll lines have been put in to Bristol, Doylestown, Quakerstown and Lansdale. The capital stock is $10,000. Mr. H. C. Worstall, is president, W. P. Church, secretary, and E. P. Hicks, treasurer.

CATALOGUES.

The Hoppes Mfg Co.

The Hoppes Mfg. Co., of Springfield, Ohio, have just issued a very elaborate descriptive catalogue and price list of their well known live steam feed water purifiers and exhaust steam feed water heaters, and of the Hoppes steam separator, which they have recently brought out. The Hoppes specialties and their admirable features are so well known to boiler users and engineers that they need no further comment here, except, perhaps, that the demand recently for the purifiers and heaters has been on such a large scale as to surprise even this enterprising company itself. The catalogue, which contains 56 pages, is well illustrated and neatly arranged, and will be sent to anyone upon application.

Chicago Belting Co.

A very attractive and interesting as well as instructive catalogue has just been issued by the Chicago Belting Co., of Chicago, Ill., makers of leather belting and dealers in mill supplies. The catalogue contains price lists and modes of manufacture of pure oak-tanned leather belting, and a special chapter on the production of dynamo belting. These latter belts are always made endless at the factory, where the company have special machinery. They also manufacture straps, round leather belting, lace leather, and deal in such supplies as belt cement, glue heaters, belt studs and tools, as well as cotton belting. Nearly one-half of this interesting book is devoted to practical information on belting, which chapters are amply illustrated and highly instructive. The cover has embossed on it a pulley over which a wide belt is running, on which appears the well known trademark of the company, the word "Reliance," so characteristic of the company's products.

Johnson & Morton.

Johnson & Morton, 26-28 Catherine street, Utica, N. Y., are distributing an interesting leaflet illustrating their new style of slate-lined fireproof junction boxes and tablet boards. The particular circuit box illustrated contains a main switch and six flush branch switches, and is very attractive in appearance. The leaflet will be sent to anyone upon application.

Bristol Company.

What appears to us to be a most complete list of recording instruments for pressure, temperature and electricity has just been issued and called a "partial list" by the Bristol Co., of Waterbury, Conn. It includes not less than 117 different varieties and ranges, and the company are continually making additions to meet any special requirements. So universally known and used are these standard instruments that an illustration of each type of instrument and their prices was all that was considered necessary to include in the pamphlet, which will be mailed to anyone upon application.

Chas. E. Billin & Co.

A publication entitled "Machinery and Supplies," published by Charles E. Billin & Co., engineers, 1533 Marquette Building, Chicago, Ill., has just made its second appearance and might be called a combination catalogue and text-book. It is published monthly by this well known firm, who carry on business as engineers and forwarding agents. The book contains catalogues and price lists of a number of manufacturers of machinery and supplies whose space varies from one to ten pages, the descriptions, cuts, and prices being furnished by each firm. Among the items in this number are descriptions of several stamp-mill equipments, articles on insulated and copper wire, power-hammer installations, wood-split pulleys, tables and other interesting information.

WAR TELEGRAPHS. The estimates of General Ludlow, recently submitted to Congress by Secretary of War Alger, provide for $195,000 for special electrical communication for the army in Cuba, Porto Rico and the Philippines.

Whitney Pocket Voltmeters.

Electric Appliance Company are calling attention in our advertising columns to the new Whitney pocket voltmeter, which is bound to find a large field of usefulness, particularly among telephone companies where an accurate voltmeter of low range

is desired. This instrument is about the size of an ordinary watch and can be very easily carried in the pocket. It has every advantage of a regular battery gauge with the additional advantage of being an exact and accurate scale.

WESTERN NOTES

CLOOS ELECTRICAL ENGINEERING COMPANY has been formed in Milwaukee, with headquarters in the Cawker building. The officers are: President, H. W. Falk; vice-president, electrical engineer, etc., Jacob Cloos; secretary, E. A. Wuerster; assistant secretary, C. H. Falk; treasurer, H. R. King. The concern will do a regular engineering business.

DAYTON FAN AND MOTOR COMPANY, Dayton, O., state that they have not shut down their factory for one hour during the past three months, but have had to run day and night shifts. Mr. E. O. Waymire says their trade has grown to such proportions as to necessitate the renting of larger quarters in the near future to keep up with their fan motor business. The company employs at present 100 hands steadily.

CRAIGHEAD ENGINEERING COMPANY, of Cincinnati, O., are furnishing their Craighead flexible brackets to the Grand River Electric Railroad, running from Detroit to Pontiac, Mich. The road will probably be 35 miles in length when completed and is likely to require 1,600 of these brackets for the complete equipment.

KEMPSTER B. MILLER, who for some time past has been superintendent and electrician for the Western Telephone Construction Company, of Chicago, will leave that concern on July 1, to take charge of the telephony instruction in the International Correspondence Schools, at Scranton, Pa., and also take up some personal lines of work which he has long desired to follow out but which time has not heretofore permitted him to develop. Mr. Miller, although a young man, has recently risen to be considered one of the leading authorities in the independent telephone field.

AMERICAN CARBON WORKS, Noblesville, Ind., notwithstanding the great increase in the machinery put into their factory, report that they are extremely busy and are working to the fullest capacity. The outlook for trade is excellent.

MASON ELECTRIC EQUIPMENT COMPANY, Chicago, requests that as its Mr. E. R. Mason has been called into active service as a member of the Naval Militia of Illinois, all orders be sent to its St. Louis office, 314 Security building.

THE CENTRAL ELECTRIC COMPANY report a number of new specialties in their house goods department, prominent being a new device for electrically lighting the incandescent gas or Welsbach burner. It is a marvelously simple device and will doubtless be appreciated by the trade, which has been asking for a device of this character.

WESTERN ELECTRIC COMPANY wishes to quote prices to central stations on Lakon transformers and transformer cut-outs.

MR. R. H. BOUSLOG, the general manager of the Peru (Ind.) Electric Manufacturing Company, writes us: "The business of this concern is in a very prosperous condition. The new line of goods, especially the new plug and plug cut-out, is popular and inquiries and orders are coming in from all directions. We have twice the number of hands employed that we had a year ago, and certainly see no reason for complaint."

CRESTLINE TELEPHONE COMPANY has been formed lately with a capital of $10,000 by W. S. Johnson, secretary and treasurer, and E. R. Law, manager, the former at Van Wert and the latter at Crestline. There is a switchboard capacity of 100 drops, and 100 subscribers at rates from $18 to $30. The local circuits are five miles in length, and toll lines are being run in different directions.

CANADIAN PACIFIC TELEPHONE COMPANY has met the cut in rates of the Western Union Telegraph Company on the Pacific coast, the cut to some points amounting to a reduction of nearly 80 per cent.

NEW YORK NOTES.

WARREN-MEDBERY COMPANY, of Sandy Hill, N. Y., are now manufacturing a full line of Medbery switches and switchboards in all their various styles. They will shortly be able to supply the market with all styles of their celebrated Medbery insulation for electric railways. It is already in great demand, and its popularity will grow.

BUFFALO, N. Y. J. L. Alberger & Son have furnished the National Electrotype Company with one 40 h. p. Crocker-Wheeler motor to drive refrigerating machinery with current from Niagara Falls. The same firm are supplying other Crocker-Wheeler motors to run on Niagara power, including the five-story candy factory of Sibley & Holmwood, for which Mr. H. A. Foster was consulting engineer.

NEW YORK EDISON COMPANY shows a gross for the five months of 1898 of $1,326,567, a gain of $270,661 over 1897 in gross and a gain of $97,263 in net. The net gain in May was $24,094.

CROWN INCANDESCENT LIGHT COMPANY, of Camden, N. J., has been formed with a capital stock of $100,000 by J. Pechin, R. Barr, J. Green, of Camden, and L. A. Repetto, of Atlantic City, N. J.

ERICSSON TELEPHONE COMPANY, of Utica, N. Y., has been formed under the laws of West Virginia with a capital stock of $100,000, the shareholders being L. P. Smith, J. F. Hemenway, A. M. Hemenway, W. C. Wilson and H. E. Higgins. The headquarters are located at Utica.

THERMO-ELECTRIC COMPANY, of New York City, has been formed by A. H. Woodbridge, Lyons Farms, N. J.; M. M. Armstrong, Philadelphia; L. S. Langville, Oscar Taussig, A. Rindskopf, H. L. Dyer and Merle J. Wightman, of New York City.

RED BANK, N. J. A. C. Greenberg has allowed judgment to be taken against him for $30,686 in favor of A. B. Fletcher on a claim as endorser on eleven notes of the Atlantic Highlands, Red Bank & Long Branch Railroad Company, of which he was president, and which is now in a receiver's hands.

THE GOUBERT MANUFACTURING COMPANY, 14 and 16 Church street, New York, has secured from the Metropolitan Street Railway Company, of this city, the contract for feed water heaters for the mammoth power station being erected at Ninety-sixth street and East River. The first installment consists of 30,000 h. p. in six heaters, horizontal type, and rated at 5,000 h. p. each. They are to be placed between the low pressure cylinders and the condensers. It is said to be the largest single order for feed water heaters ever placed in this or any other country.

BROOKLYN TROLLEY CARS on Decoration Sunday carried over 1,000,000 passengers and could have handled more had there been cars enough and power enough to drive them. The traffic was admirably taken care of.

NEW ENGLAND NOTES

AMERICAN ELECTRICAL WORKS, of Providence, by way of a souvenir for Decoration Day, issued a steel portrait of Abraham Lincoln, accompanied by a quotation from his Gettysburg address, at the dedication of the National Cemetery there.

WILMOT & HOBBS MANUFACTURING COMPANY, of Bridgeport, Conn., are making extensive additions to their manufacturing plant, which consists of two large buildings. These buildings are to be used as an engine and plating room and a machine or manufacturing building. The engine and plating building is about 60 feet wide and 100 feet long, two stories high, steel frame construction, with brick side walls and concrete floors. The machine building is about 80 feet long and 135 feet wide, and three stories high. This building is of steel skeleton construction throughout. The floors are designed for heavy loads and are carried on corrugated iron arches supporting concrete filling. The aim in the designing of these buildings has been to get the most convenient structures possible and the maximum amount of light consistent with stability of structure and with economic construction. The designs of the buildings were made by the Berlin Iron Bridge Company, of East Berlin, Conn., who furnish and erect the structural steel work.

HOLYOKE, MASS. The Lyman Mills, which is the largest mill corporation of Holyoke, Mass., employing about 1,500 hands, are a progressive concern, and their recent adoption of electric power for the operation of their machinery will undoubtedly have a marked influence upon many other firms in the vicinity. The Westinghouse Electric and Manufacturing Company has installed for the mills a 250 kilowatt, 440 volt, two-phase, 3,600 alternation generator, direct connected to an Allis-Corliss engine running at 120 r. p. m. Six Westinghouse type "C" motors, varying in size from 30 to 75 horse power, are used for the operation of spinning frames, looms, the machine shops, etc.

WATERVILLE, CONN. The new building which the Waterville Cutlery Company are erecting will have a steel roof which is being erected by the Berlin Iron Bridge Company. The trusses are steel, and the covering is corrugated iron lined with the Berlin Company's patent anti-condensation fireproof lining. The building is 21 feet wide and about 100 feet long, and is to be used as a forge shop in one end, and in the other will be located the boilers and engines.

FOREIGN OPINION.—The long-established weekly eclectic magazine, The Living Age, never deserved its title better than now; for its presentation of English and Continental opinion on the various aspects of the war between the United States and Spain is fresh, full and widely representative; yet it does not trench at all on the other admirable features of the magazine.

BRIDGEPORT, CONN. The Canadian Bryant Electric Company has been organized at Bridgeport with a capital of $5,000, in 200 shares of $25 each, $2,500 paid in. The subscribers are: W. C. Bryant, 72 shares; L. W. Eaton, 34; J. B. Hubbell, 30; E. W. Marsh, 30; H. A. Hubbell, 24; E. M. Scribner, 10. The company has a factory at Montreal.

PORT CHESTER, N. Y. The new power house now being erected by the Port Chester Street Railway Company is a building 45x84 feet, and consists of a boiler room, engine and dynamo room. The building has brick side walls, in which are built steel columns, supporting steel truss roof. In the engine room is a traveling crane arranged so that any part of the engines or dynamos on the floor below can be readily lifted and moved from one place to another. The power house is built in a substantial manner, and is a well-designed modern station in every respect. The steel work for this building was designed and is being erected by the Berlin Iron Bridge Company, of East Berlin, Conn.

American Electric Vehicle Co.

C. F. Smith, president of the Indiana Bicycle Company, has returned from Chicago, where he went to complete the deal for the controlling interest in the American Electric Vehicle Company. The arrangements for the purchase were satisfactory and Mr. Smith and his financial associates secured the stock. The company was immediately reorganized, with C. F. Smith, president and general manager; Philip Goetz, vice-president, and L. S. Dow, secretary. The entire business of the carriage company will be removed to Indianapolis, and the manufacture of electric carriages will be begun. The new industry will give employment to from 1,000 to 1,200 men.

General Electric Automobile Co.

The General Electric Automobile Company has been organized under the laws of West Virginia, with an authorized capitalization of $2,500,000, divided into 50,000 full-paid, non-assessable common shares of the par value of $50 each. There is no preferred stock nor any bonds. Of the total common stock authorized there have been issued 35,000 shares, 20,000 of which are held intact by the controlling interests, leaving 15,000 shares taken over by a syndicate. As an asset for future use there remain in the treasury 15,000 shares. It is also understood that the treasury will have at the beginning of business a large cash balance. The head offices of the company are in Philadelphia. The Board of Directors includes J. A. Brill, Prof. W. D. Marks, Rudolph M. Hunter and John H. Noblit.

ADVERTISERS' HINTS

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, Ill., advertise Whitney pocket voltmeters reading to five volts. These little instruments are about the size of an ordinary watch and are easily carried in the vest pocket.

C & C ELECTRIC CO., 143 Liberty street, New York, call attention to their marine type generating sets in sizes from 2½ to 15 k. w. In these combinations their well known closed type of ironclad dynamo is used, making practically a waterproof outfit.

THE WAGNER ELEC. MFG. CO., St. Louis, Mo., advertise alternating current ceiling fan motors for 7,200 alternations, at prices that must prove interesting.

D. A. HEUBSCH & CO., New York, get out a year book which proves an excellent souvenir for presentation to customers.

HENRY R. WORTHINGTON, New York, about a year ago, began fitting all Worthington pumps with forged steel valve motions and links. Although costing more, they say the difference is worth the expense.

THE UNION STORAGE BATTERY CO., 1063 Hamilton street, Cleveland, Ohio, claim their battery cannot be excelled as accumulators, regulators, boosters, equalizers, etc. It was described in detail in our last issue.

THE WARREN-MEDBERY CO., Sandy Hill, N. Y., the manufacturers of the new Warren inductor alternator, publish a full list of their sales' offices.

THE HOLTZER-CABOT ELEC. CO., Boston, Mass., call attention to the improved Holtzer automatic gas burner.

Quiet and Strong Conditions.

The following quotation from Bradstreet's sums up the situation neatly: "Unprecedented foreign trade totals, involving heavily increased shipments of breadstuffs, provisions, raw cotton and manufactured products; flattering crop prospects, pointing to very large yields of wheat and most other cereals, as well as cotton; profitable railway operations, as reflected in relatively heavier gains in net than in gross receipts; activity in nearly all lines of manufacturing except some textile branches; prices for most staples showing heavy advances over the preceding year; bank clearings, exceeding all previous records at this date; a volume of new demand limited in the East and South to midsummer dullness, but in the West and Northwest comparing favorably with records of previous years, and a low rate of business mortality, are all features of the general business situation at the present time."

During the week 8,292 shares of Western Union were sold, closing at 91¾. Of General Electric, 8,518 shares were sold, easing off from 39 to 37¾. In Boston, American Bell Telephone went down from 275 to 271 on sales of 583 shares.

Copper in New York last week was 11.87½. Heavy steel rail, Eastern mill, $17.50. Lead, New York, was 3.87½.

ELECTRIC LIGHTING

The Proper Illumination of City Streets.

BY HENRY HOPKINS,

Superintendent Street Lighting, New Haven, Conn.

THERE probably has been no subject connected with modern municipalities that has come to the front more in recent days than the question of efficient street lighting. And the field is one that a great deal of thought and study can be expended on with profit by those connected with city affairs. Well lighted streets make it safe for us all to travel about after nightfall, and also show a prosperous and wide-awake community.

The word "proper" as used in connection with the subject must be used as directly referring to the particular era or age in which the comparison is made. Thus the city of New York when it passed an ordinance in 1697 required that the residents of every seventh house should place a candle burning lantern out of the second story window suspended on a pole, followed by Boston in 1774 with oil burning lanterns. The people of that age called it proper street illumination, because it was the best obtainable at that time. We recall their existence as "has beens." The following homely poem will convey the idea:

> In olden times along the street
> A glaring lantern led the feet
> When on a midnight stroll,
> But now when night is nigh
> We catch a piece of lightning from the sky
> And stick it on a pole.

The problems that we have to overcome are dark pavements, angular streets and the foliage on the trees. I believe the time will come when light colored pavements will be considered in connection with street lighting; angular streets may be overcome to a certain extent, but the foliage on the trees is like the candidates for our places, always haunting us. Judicious trimming will greatly assist in good street lighting; the lamps are not to blame and the trees certainly are not, for they were there first.

What are the requirements for satisfactory street lighting? We can find many, but the four that present themselves to me are:

First. The most modern system. It should be borne in mind that prospective residents and manufacturers consider this point.

Second. The most reliable system at all times under adverse circumstances, such as high winds and severe storms.

Third. That system in which it is nearly impossible for evil disposed persons to interrupt the service.

Fourth. And an all important factor—the system giving under all circumstances the most illumination blended with the fulfillment of the three preceding requirements. Leave one of them out and the general result desired is lost. The first one can be easily answered, as its birth is of recent date. For the consideration of the second requirement study the above table.

FIG. 2.

EFFECT OF HIGH WIND ON LIGHTING SERVICE.

RECORD FOR NIGHT OF NOV. 9, AND MORNING OF NOV. 10, 1897.

Lighted, 4.30 to 5.30 P. M. Extinguished, 5.45 A.M.

Velocity of Wind per Hour.	Electric		Welsbach.		Plain Gas		Naphtha.	
	Out.	Broken.	Out.	Broken.	Out.	Broken.	Out.	Broken.

Totals	..	..	1	..	8	1	77	..

Shortly before 8 p. m. there was a gust of wind that registered 60 miles.

Number of electric lamps	442
" of Welsbach lamps, gas	105
" of plain lamps	633
" of naphtha lamps	512
Total	1,692

The third requirement can be answered by any school boy of the present day.

For the fourth consider Fig. 1.

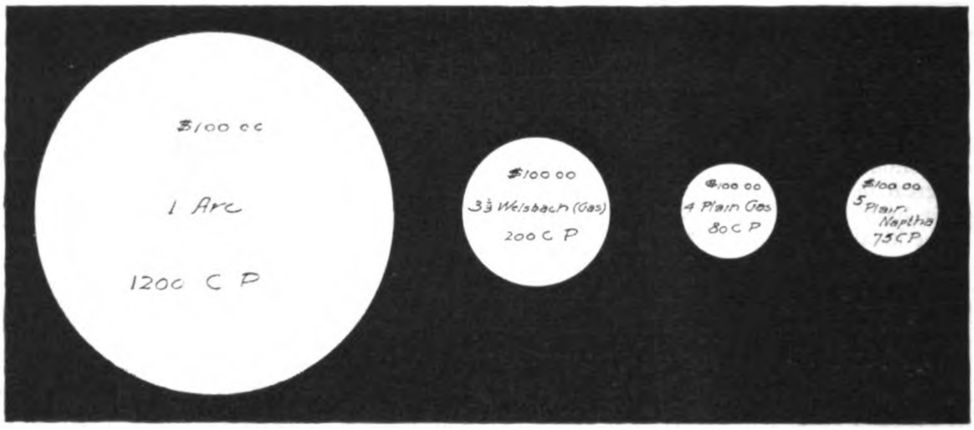

FIG. 1.

This cut shows the light producing power obtained for $100 on the following basis:

One 1,200 candle power arc costing $100.

Three and one-third 60 candle power Welsbach gas lamps at $30 each, 200 candle power for $100.

Four 20 candle power plain gas lamps at $25 each, 80 candle power for $100.

Five 15 candle power plain naphtha lamps at $20 each, 75 candle power for $100.

That the electric arc light is not liable to be superseded at present is shown by the fact that in our city it was introduced in 1884, and since that time under nineteen committees and four superintendents not an arc light has been discontinued, while 1,081 gas and naphtha lamps have succumbed to progress. Yet at this time I desire to put myself on record as admitting that for certain places and under certain circumstances arc lights are out of place.

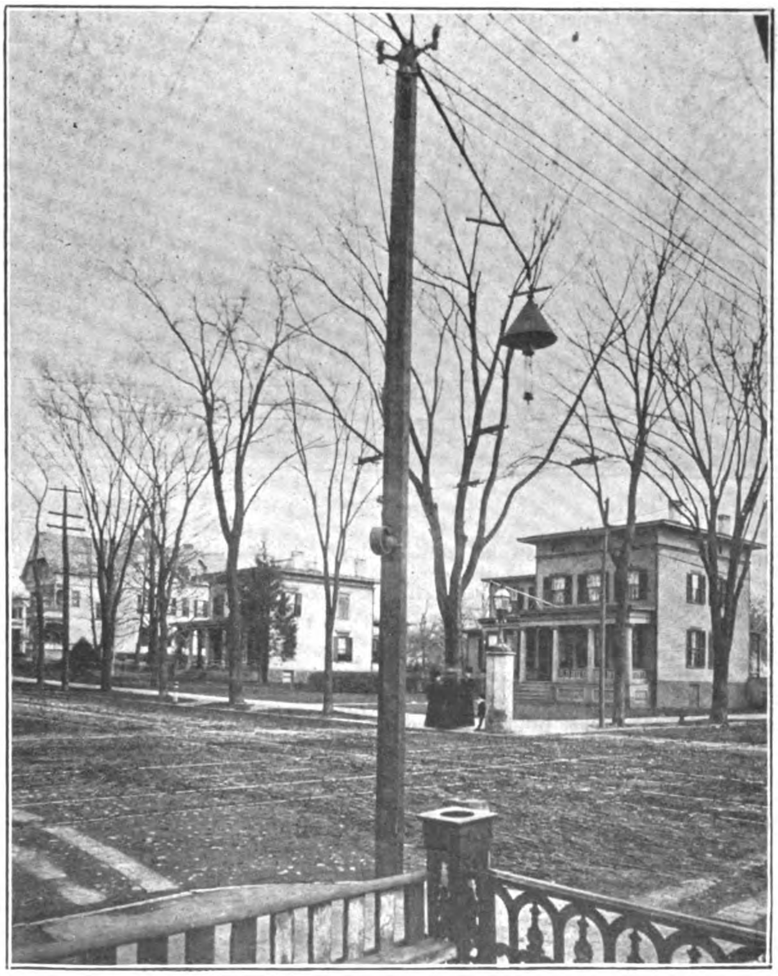

FIG. 3.

The locality should govern the system and it should be practical lighting, not political lighting, and thus an efficient service will be built up. On account of the high candle power of the electric light it is especially adapted for parks, bridges, railroad crossings, in front of public buildings and for the business sections and on corners. While as an auxiliary to the above, Welsbach gas lamps can be used between the blocks and on residential streets where they are angular and the trees are dense. In outlying districts, where there are no gas mains, naphtha lamps can be used to advantage. Locating of lamps can be done more advantageously after dark. A few illustrations are here presented.

Fig. 2 shows a junction of three streets, a trolley track and a watering trough. The light is placed on a pole, a light on arm extension would not distribute the light evenly.

Fig. 3 shows an avenue and cross street with double trolley tracks on both streets. An arm is here used to convey the light bearer as near the center of the most dangerous part of the roadway as possible, yet the cross walks receive their share.

Fig. 4 shows an elbow made by three streets joining: notice how nicely the lamp is poised so that all points receive an equal amount of light.

Fig. 5 shows a lamp placed on a pole, now changed to arm extension; the cross street opposite is now benefited instead of the building. We should light the streets instead of the sides of buildings.

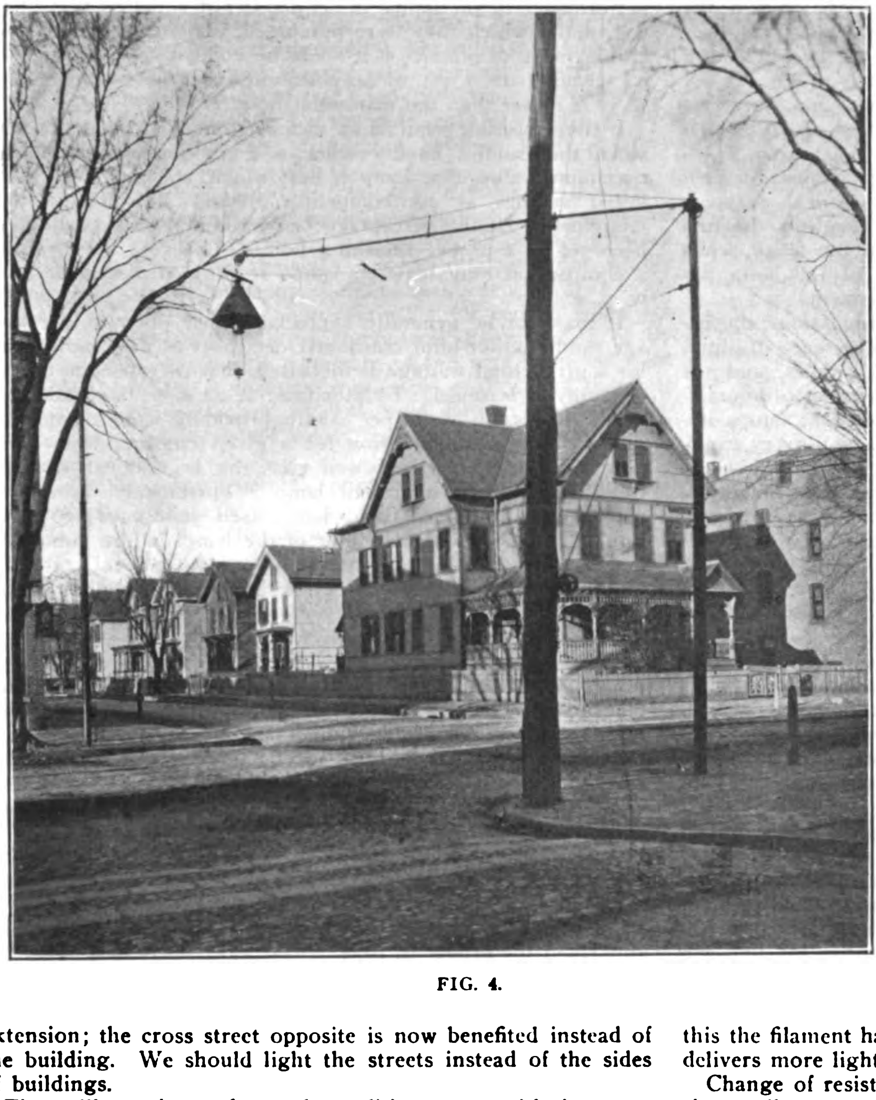

FIG. 4.

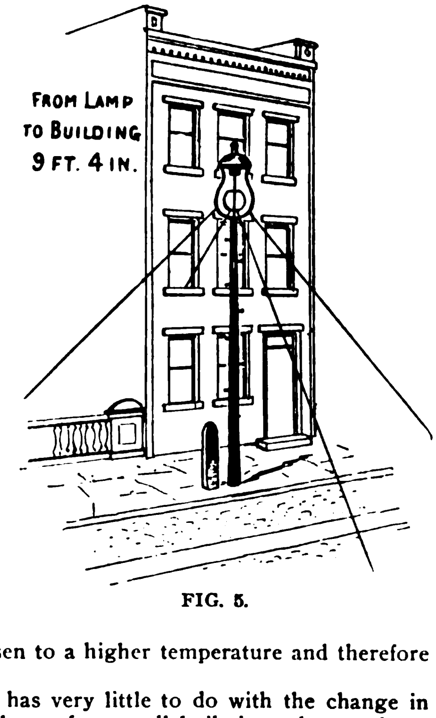

FIG. 5.

These illustrations of actual conditions met with in street illumination in our city indicate most clearly which system all points considered is most valuable. The preceding tables showing the relative candle power of the various systems and particularly treating on the reliability under adverse circumstances as considered in regard to outages must form a conclusive argument. While Welsbach lamps give a fair amount of light, yet the liability of the mantles to crumble after being lighted an i at a time when it is impossible to renew them owing to non-patrol of the lights creates a certain amount of prejudice, which at the present time has not been overcome.

I believe the time will come when the arc light of great candle power will be subdivided into three or four parts and so scattered in locating, and that in the case of illuminated arches between the blocks as used in some cities as an adjunct to arc lamps, the semi-circle will be inverted so as to throw the rays of light down rather than up. And I also predict that the tower system will soon go out of use.

Important Considerations in Lamp Tests When Determining the Best Available Lamp for Central Station Use.[1]

BY S. EVERETT DOANE.

I WANT to begin by saying that an incandescent lamp is of no particular candle power. It is given a rating, but such rating is only partially descriptive.

It is capable of delivering many different candle powers, at as many different voltages. It can, however, deliver only one candle power a tone wattage. It is obvious, then, that, irrespective of resistance, if the surface of the fiilament does not change, the candle power of the lamp will remain the same, providing the wattage delivered to it is constant.

Neglecting for the moment all the exceptions having to do with the color of filament surface, the character of same, and considering for the time being all filament surfaces as alike, the area of the surface has all to do with the candles and w. p. c. at varying voltages. This being the case, it is, of course, clear that a lamp giving certain candle power at 100 volts, will deliver candles if operated at 104 volts, due simply to the fact that more energy is put into the filament, and in radiating this the filament has risen to a higher temperature and therefore delivers more light.

Change of resistance has very little to do with the change in the candle power of a lamp, for a well built incandescent lamp does not change its resistance materially throughout its effective life, although its candle power changes considerably. This being the case, it is obvious that any change in candles without a change in watt consumption must be due to change in the surface of the filament.

How should incandescent lamps be rated? This is not an

[1]Abstract of a paper read before the N. W. Elec. Assoc., June 11, 1898.

idle question. It has been the misfortune of some lamp manufacturers to lose competitive tests, when really they have won, because of an improper analysis of the results by the purchaser, though the purchaser has acted in perfect faith, honesty and to the best of his judgment.

It very frequently happens that the maximum candles are reached, as it may have here, in less than five hours. Observation should always be taken early enough, so that at least two readings, if the lamp rises much in candles, come on the upward portion of the curve. The importance of the statement will be apparent when you note that in this case, if we assume that the readings were not taken until 100 hours, the lamp would have been shown to have risen only 5 per cent., about .8 of a candle. If the readings had been taken at the end of about 170 hours, it could have been assumed that the candle power had not changed from the beginning, and the fact that, having been a rocket, it is now a stick, would be lost sight of.

It is not unusual to see the reports of lamp tests in which the candle power of the lamp is said to have "remained unchanged for many hours." There is a very small chance that this is true of any lamp test. An inspection of the curve for the remainder of the life of the lamp usually shows that the lamp had probably risen very high in candles, and that the first reading after the initial had been taken at the time when the decreasing candles were the same as they were initially, having in the meantime been much greater.

I believe there is no ground for debate on the two following statements:

First—The candle power of an incandescent lamp never remains absolutely constant, and, barring the first sharp rise, it constantly falls.

Second—The curve of change in candles in an incandescent lamp is nearly a straight line, and for all practical purposes can be considered as such. This, of course, neglects the first rapid rise in candles and the sudden slump at the finish, when the defect, which finally causes the failure of the lamp has reached the acceleration period of its development.

In spite of curves, figures, statements and discussions, the belief is still general that the sole gauge of the difference of illuminosity is the difference between the initial candles, and the candle power at the end of a pre-determined number of hours.

This is rarely the case. Almost all incandescent lamps immediately rise in candles. This preliminary rise is very rapid. The maximum candles are frequently reached after the first one or two hours. Such being the case, what is the true initial candle power of a lamp under test, and how much has the candle power rating to do with the ultimate decision of the would-be purchaser?

Why should a lamp be bought and termed "16 c. p." when within an exceedingly short space of time, it gives 18 or 19 c. p.?

Should a purchaser of a three watt lamp be pleased if by its rise in candle power it produces light at the rate of 2½ watts per candle, but subsequently suffers a rapid decrease in brilliancy, because of this high filament temperature? Would it not have been better if illumination at the brilliancy produced by filaments at a 2½ watt temperature was desired, to have consulted some lamp engineer, with a view of producing this extraordinary condition in the best engineering manner? Would any of you dream of over-loading your generators, deliberately closing your eyes to their obvious over-heated condition, and invite final disaster, because your generators were rated to operate at a given number of amperes, and your ammeters lied?

Is it wise to buy lamps labeled 16 c. p. if after the first five hours they rise to 18, and subsequently fall to 14 c. p. or less, giving you very bright and comparatively very dim lamps on your circuit side by side? But such lamps have caused lamps really well made to be considered inferior because the area of candle power of the latter was less, although the real maintenance of candle power was superior.

Why should a manager desire a lamp which rises in candles? If he buys a 16 c. p. lamp, is he purchasing a lamp which he wishes to deliver 18 or 20 candles or more after a few hours? Is he not deceiving himself? Would it not be better for him to understand that he is purchasing an 18 c. p. lamp? Would it not be better for him to buy one actually 18 or 20 c. p., which would not rise in candles? He could thus secure the benefit of the difference between 16 and 20, when the poor lamp was rising, and before it reached the peak of its curve, and at the same time view the conditions of illumination with his eyes wide open.

Fortunately, it is not essential, in discussing a lamp test, to find just the height to which a lamp rises, as the most satisfactory lamps do not rise in candles, or at least rise very little, and readings on these lamps will show that the candle power curve almost from the beginning is very close to a straight line.

To refer back to the original question, what is the proper rating? Should not the definition of initial candle power be the maximum candles during any part of the life? Should not the difference between the maximum and minimum candles be the gauge of the lamp's performance? It would seem to me that by far the best rough method of analyzing a lamp test is to add the per cent. increase to the per cent. decrease in candles, and call it all decrease. A few of us are guarding against this rise in candle power and trying as hard to overcome it, as we are the fall.

Watts per candle rating: After the test it is not unusual for the purchaser to demand that lamps delivered shall not exceed the w. p. c. of the lamps under test, so that the lamp manufacturer is immediately obliged to build lamps which shall average less watts per candle than the lamps under test, with a resulting disappointment to the station manager, because the performance of the lamps in service is not equal to that of the test, under which they were purchased. It would point toward a uniformity of practice if it could be understood that the w. p. c. specified on a set of specifications are the average initial w. p. c. rather than the maximum limit.

If the smashing point of an incandescent lamp is at that time when the candles have reached a given percentage of their maximum value, that lamp is best which, starting at the same initial candles as its competitor, makes the nearest to a straight line to the percentage of maximum candles which has been set as a proper smashing point. This, of course, affords a comparison only between lamps starting at the same initial w. p. c.

It may not be generally appreciated that the cost per average candle power-hour constantly decreases as the candle power for a given total wattage is increased, that is, when the average economy is lessened. To illustrate: A 24 c. p. lamp taking 60 watts, that is, 2½ watts per candle, providing it does not break, gives a greater illumination for a given consumption of watt hours, through a period well past the economical smashing time, than a 20 c. p. 3 watt lamp. Fortunately, or unfortunately, an incandescent lamp lends itself quite easily to deception. A little rough handling of the lamp on the pumps will blacken the filament and reduce its candle power. But this blackening is radiated after a few hours, so that the filament again returns to its steel gray color, and the candle power to that normal for a treated surface.

Have I fully illustrated this point? A lamp of given candle power at a calculated voltage, which has had its filament lightly blackened on the pumps will give its candle power at a voltage higher than that calculated, because the blackened surface of this filament radiates the heat much more rapidly than the normal gray treated surface, and consequently does not get hot enough at its intended voltage when measured initially, but after several hours this black, sooty coating has been radiated to the bulb, and the filament returns to its normal color. We have, then, a lamp of lower voltage, and normal characteristics operating upon circuits where the voltage may be one, two or more volts greater than that necessary to produce the determined candles at the proper w. p. c.

The appearance of a lamp, whether it be bright or dim, is governed by the temperature of the filament, which is measured (speaking roughly) by the w. p. c. This has much to do with the light and shade in the illumination of an apartment, a show case, or window. This, of course, if the difference in w. p. c., not between the initial and final, but between the maximum and minimum in any part of the life. That this argument is perfectly logical will be seen when it is followed to its legitimate end. The distribution of illumination throughout any apartment is good or poor, in proportion to the difference in quantity and quality of illumination or areas which come under the eye at the same, or nearly the same time. This argues in favor of the concealing of the source of light, a method of illumination which has been found so effective for stage purposes. A great difference in brilliancy should not be

apparent to the eye, as the eye apparently adjusts itself to the most brilliantly lighted spot, and others are darker in comparison. It is the old difficulty of looking toward a brilliant spot of light, and attempting to outline objects near it.

It is very difficult for even a lamp expert to see the difference between a 20 c. p. and a 16 c. p. lamp if both lamps are operating at the same watts per candle. The greater the surface of the filament, however, that is, the higher the candles, the brighter the lamp looks at the same w. p. c., but this same difference is not so great that an essential difference will be noticed between a 20 and a 16 c. p. A 16 c. p. lamp delivering its 16 c. p. at 3.1 w. p. c., beside a 20 c. p. lamp, delivering its candles at the same efficiency, would not attract notice. If this 20 c. p. lamp had dropped to 16 candles, without changing in total wattage, thereby delivering its 16 candles, as it actually would in practice, at about 3.6 w. p. c., the difference in candle power would be immediately apparent to the consumer. The difference in the quality of the light delivered by the two lamps is what would have called this to his attention.

The color of the light delivered by the two lamps differs widely. The candle illumination, as determined by the photometer, may be 16 c. p. The effective illumination from the standpoint of the individual is a vastly different thing, and is not capable of being measured.

To illustrate. We have here two lamps, one of which is delivering candle power at 3.1 watts, the other delivering candle power at the same total wattage, it being a lamp which has burned a long time, and has dropped to candle power. We have here another group of two lamps delivering different candle powers from the above, but the same, that is 3.1 w. p. c. We think this will make the distinction between w. p. c. very clear.

The general opinion is unmistakably in favor of this view. The light from a number of lamps of widely varying candles or of the same candles of even slightly varying efficiencies grouped together is painful to the eyes, and in a manner not wholly appreciated, grates upon the feelings of those who have occasion to make use of the illumination. Of course, when the source of light is not apparent, the objects illuminated, if of different colors, reflect only a portion of the rays from the light spectrum, because of their color-selective quality, and therefore lamps of varying brilliancy may be used without the painful inconvenience which would result from the naked lamps being exposed to view.

It is being more generally appreciated to-day than ever, that there must not be a variation in the apparent efficiency of lamps side by side. That is, some must not be bright and others dim.

I say "apparent efficiency" advisedly. A 10 c. p. lamp appears to be of slightly less efficiency than a 20, even when it is of the same efficiency. To procure perfect satisfactory illumination, for instance, with the source of light in range of the vision, 100 c. p. lamps at 3.6 w. p. c. give better satisfaction if when used with smaller units, the latter are burning at higher economy, say 3.1 watts.

Blackening of the lamp bulb is responsible for very little of the drop in candle power. The increase in area of the filament surface is responsible for most of it. The blackening is indicative of the service a lamp has given, if its characteristics are known. Blackening is largely, if not wholly, a chemical effect, but the lamp which rises higher must always blacken more when compared with a lamp which does not rise in candles. We do not want black lamp bulbs any more than we do bright and dim lamps.

Almost every lamp rises in candles. Choose the lamp which rises least, and discount even that rise.

To sum up: Lamps do rise in candles. Everything is being done to obviate this rise and eventually it will be entirely avoided. We have not come to this yet, but we are nearer than ever before.

Decreasing the rise will do as much to maintain the uniformity of illumination as decreasing the fall of candles.

Bright lamps and dim lamps are equally objectionable, and it is my hope that I have made very plain what I started out to show, viz., that the most important consideration in determining from life tests the best available lamp for central station use, is that the true initial candles of a lamp under test be properly determined. They in my judgment are the maximum reached.

MISCELLANEOUS

Electric Smelting at Sault Ste. Marie.[1]

BY WILLIAM SMITH HORRY.

AFTER calling attention to the manner in which ore was formerly smelted, bringing out the point that only about half the intensity of the heat can be attained by ordinary combustion that could be obtained with the electric furnace, and that in smelting by combustion it is impossible to take advantage of the full heat of the fuel, because it has got to be sent out in a state not fully oxidized, Mr. Holly continued as follows:

There is not much hope for improvements in the regenerative furnaces that will make it possible to attain, even approximately, the degree of heat that can be developed by electricity, and even if the gas or oil furnaces were so designed that a high intensity of heat could be developed there is still the difficulty that no crucible would stand it, as all substances otherwise suitable for crucibles are in a liquid or gaseous state at this temperature. But with the heat developed in the interior of a vessel by electricity this difficulty does not apply. Thus we see molten masses of carbide of calcium weighing a ton or more at probably 3000° C. contained in a cast iron receptacle that would be melted if it reached a heat of 1100° C.

Another merit of this method of smelting lies in the fact that the temperature is easily under control. All processes require a precise degree of heat at which they are carried on most advantageously. In gas making and several other cases the heat is judged by its color; in any case it is judged and rarely measured. But in the electric furnace the heat can be indicated very accurately by the wattmeter, so that results, once attained in this apparatus, can always be duplicated with ease.

At Sault Ste. Marie we obtained from some of the mines at Sudbury, Ontario, a sulphide nickel ore containing generally about 3 per cent. of nickel. Its general composition is, sulphur 42 per cent., combined with iron, nickel and silica. It was proposed to experiment on this ore, extracting the sulphur to be used as sulphuric acid in paper making. The ore was roasted in a specially designed regenerative furnace, and a purple matter was produced, still, however, containing 7 per cent. of sulphur. Had this process of roasting continued longer the sulphur would have been all reduced in time, but after a certain point is reached it is a pure waste of fuel to continue the roasting process.

The matter was now ground up and mixed with lime and carbon as reducing agents, and the whole composition was served into an electric furnace. After fusing, the resultant metal was found to contain only 2-100 per cent. of copper. The alternating current only was used. I am informed by metallurgists that this practical elimination of the sulphur is gratifying, and that the use of the electric furnace here is an improvement, as it performs the service cheaply that can only be done expensively in other ways. Two types of electric furnace were used and the results we obtained from them differed widely. One was a crucible serving as one electrode, with a carbon pencil movable perpendicularly as the other pole. This pencil was drawn up as the melting proceeded and as more mixture was added; then, when the crucible was full the current was shut off and it was allowed to cool. On removing the contents of this crucible a brilliant lump of metal was found at the bottom of the pot. This was analyzed and found to contain 40 per cent. nickel, 28 per cent. iron, 12 per cent. carbon, 15 per cent. silicious matter, no sulphur, and 15 per cent. as yet undetermined. There was also found much iron in the charge, all containing nickel. There was slag, too, of course, and some unreduced composition. It will be noticed that the nickel had separated from the iron, and in subsequent experiments with larger charges this effect was more marked, so that it seems highly probable that nickel in a fair state of purity can be obtained in this way by this process.

The second furnace we employed was continuous in principle. There were two electrodes side by side with a bridge between them, the reduced metal running out of the sides as fast as it

[1]Abstract of paper read before the convention of the N. W. E. Assoc June, 1898.

was formed. In this furnace we found indications of very rapid smelting, the mixture of ore being reduced as fast as one man could shovel it in, the metal in the meantime pouring out of the sides. The iron from this furnace contained 7 per cent of nickel and was high in carbon. It is very slightly magnetic, and when cast it is found to be 40 per cent. stronger than cast-iron. It is so hard that it can be used as a cutting tool in a lathe and cuts rough iron castings with ease.

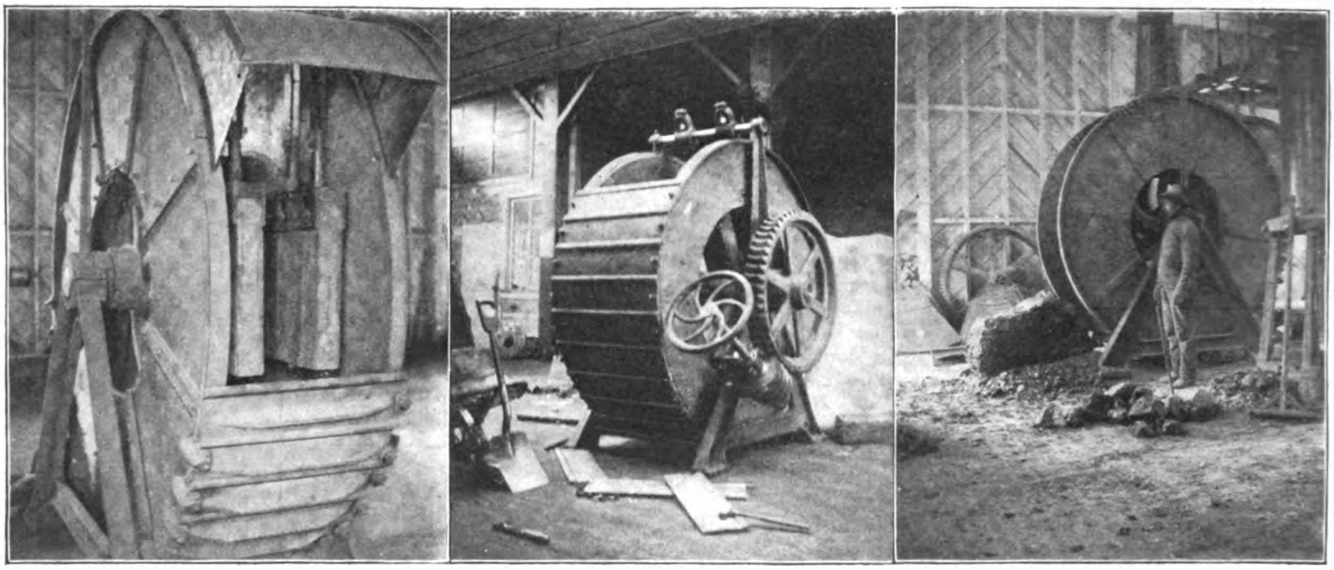
The smelting of the carbides has for some time been placed on a firm basis and as now carried on is an exceedingly easy process. There have been no changes lately in the methods announced five years ago, but the apparatus employed has been improved, and continuous furnaces are now almost exclusively employed. As our carbide furnaces are to be used in the future for the smelting of ores, a short description of them may not be out of place. They are large, cast-iron drums and resemble a spool upon which cables are wound. On the two outside peripheries iron plates can be clamped at will, and these serve to keep in the ores to be reduced. The drum is mounted on a shaft and can be slowly rotated by suitable gears.

The electrodes are carbons fixed side by side, their points touching an imaginary line drawn horizontally through the axis of the furnace. The heat due to the resistance of the ores is developed between these two points—as the ore is reduced the resultant metal lowers the resistance of the furnace and the ampere meter rises. When this occurs the furnace is slowly rotated and by this movement the metal is drawn down, away from the electrodes, and fresh ore is also brought between them to be acted on in like manner. Plates are affixed to the periphery of the furnace to keep the mixture in. The reduced ore cools within the furnace and can be extracted cold at the other side of the drum after removing the plates. At Niagara a 500 h. p. furnace of this type is now being erected. It is making calcium carbide, and will take alternating current at 220 volts potential. It stands 15 feet high. The separation of metals is entirely feasible in this furnace, because they cool undisturbed while the smelting of fresh ore continues. We have not found this effect at all in furnaces that tap out the metal as it is formed.

The adjustment of this furnace is to be automatic, a small motor controlled by an ammeter rotating the drum and keeping the current constant.

Taking it altogether, investigation in the electric smelting of ores is by no means simple. It requires skill in the manipulation of large currents, coupled with an intimate knowledge of the best practice in metallurgical operations and a thorough acquaintance with their chemistry—three accomplishments rarely found at the present time in one man.

If the heat is not right or if your proportions of reducing agents are not correct, or if some additional chemical action takes place other than the one you are expecting, it is sometimes difficult to ascertain precisely where the fault lies and where to apply the remedy, the more especially if all these faults occur at the same time. But an effect, once produced, however slight it may appear to be, can invariably be elaborated by applying known principles, and there is in consequence every reason to expect great things from the electrical method of smelting.



The electrodes and the opening into which the mixture is fed. Furnace showing the gearing by which it is rotated. Furnace showing 1,000 pounds of carbide just extracted.

THE HORRY PROCESS OF MAKING CALCIUM CARBIDE.

Transformer Regulation.

BY A. R. EVEREST.

THE "regulation drop" in a transformer is a drop in voltage at the secondary terminals of the transformer when delivering current, due to internal losses in the transformer itself, the primary voltage remaining constant.

Apparently the easiest way to determine the regulation of a transformer would be by direct measurement of the voltage at the secondary terminals; first, when the transformer is carrying no load, and secondly, when the transformer is carrying full load, the difference between the two being the regulation drop, provided the primary voltage is kept constant.

In practice, however, this test is attended with a number of difficulties, so great, in fact, as to render the test perhaps the most difficult and unsatisfactory of all transformer tests. Even when the voltage on the primary side is observed by an independent voltmeter (and step-down transformer) it may frequently happen that the temperature co-efficients of the two voltmeters are not alike, producing discrepancies in the readings, which, in themselves small, produce a large percentage error in the quantity to be finally determined.

Absolutely steady readings are also desirable for the success of this test, a condition which is very seldom attained. The pulsations of a slow-speed engine reflected on the voltmeter needle are often sufficient to make the test absolutely worthless.

There are several other minor factors which tend to disturb this test. Most of them can be met independently, as by exchanging voltmeters between readings, by taking large numbers of readings at each point and averaging results; and so on, but experience continually shows that with the greatest care the results obtained by this method cannot always be relied upon.

Perhaps the hardest point of all in connection with the regulation test as commonly made is the difficulty of persuading the station electrician who makes his own tests that his results, often absurd, are open to question. But since the losses creating the "regulation drop" in a transformer can be independently measured, the calculation of the regulation from these observed losses becomes a simple matter.

The "regulation drop" in a transformer is caused by two

losses. First, the energy loss, or CR. drop in the transformer windings, secondly, the reactive drop, or "inductance" of the transformer. In certain special cases we must also take into consideration the effect of the magnetizing current in the primary, since when the latter is relatively large it produces a phase displacement between the primary and secondary currents and has the same effect on regulation as an increase in the reactive drop.

When this phase displacement is so small as to be insignificant, the calculation of the drop of the transformer is reduced to the resolution of a right-angle triangle. We draw for the base line the total energy drop, including that in the transformer and in the external circuit.

Perpendicular to this is laid off a line representing the reactive drop in the transformer. (We are here assuming that the external load is non-inductive.) The hypothenuse joining these two sides of the triangle now represents the primary applied voltage. We may call this 100 per cent.

If the reactive drop is, say 3 per cent., the horizontal becomes the square root of 100^2 minus 3^2, or roughly, 99 per cent. If the known CR. drop in the transformer amounts to 2.2 per cent., we have left 97 per cent. voltage, (= 99.2 per cent. — 2.2 per cent.) at the secondary terminals, as compared with the primary input, or, in other words, there is 3 per cent. regulation drop in the transformer.

In many cases, however, especially when testing an unknown transformer, it is necessary to take into account the effect of magnetizing current. The calculation is then not quite so sim-

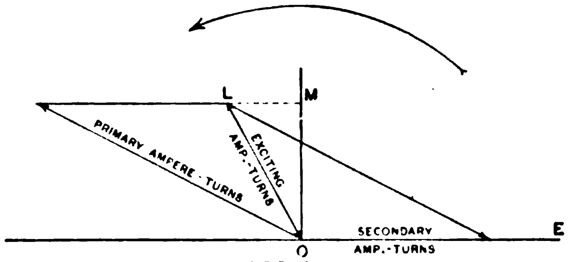


FIG. 1.

ple, but by means of the method shown below the determination can be made with the greatest accuracy. This method has the advantage of appealing directly to the eye by means of the well-known "transformer diagram."

Fig. 1 shows the relative directions of secondary current, primary current, and resultant magnetizing force and flux. O L is the primary exciting current at no load. It consists of two components, O M the true magnetizing component in phase with the flux O M, and M L, at right angles to this, which is the energy component representing the energy expended in core loss. When the secondary circuit is closed the primary current will adjust itself in magnitude and direction so as to maintain the vector O L as resultant of primary and secondary magnetizing forces.

The magnetic flux O M generates in the transformer windings a voltage O E, 90 degs. behind the flux in phase. This is the active voltage of the secondary circuit, and also appears as a counter e. m. f. in the primary circuit, where it is shown as O I. (Fig. 2.) It is here assumed that the secondary circuit is non-inductive, hence the secondary current is in phase with the induced e. m. f., O E. (For simplicity we also assume that the transformer has a 1:1 ratio.)

The voltage impressed on the primary to maintain the secondary current must be the resultant of three components (Fig. 2), namely, I O, opposing counter e. m. f. 90 degs. ahead of flux O M; D I, overcoming primary; C R, drop in phase with primary current; R D, opposing reactive drop, and 90 degs. ahead of primary current. The resultant of these is O R, which is primary impressed voltage.

It will be noted that this primary voltage O R is really the resultant of two values R I the primary impedance drop, and I O the secondary induced e. m. f. If we can calculate these, and know the secondary C R, we have the regulation at once.

It will be observed that any increase in magnetizing component increases the lag between primary current O P and counter e. m. f. O I. Since the base line I O of primary impedance triangle (the C R drop) must be always parallel to O P (the primary current) it follows that an increase in magnetizing component will swing the primary impedance vector I R more into phase with the secondary induced volts I O, increasing the value of the primary impressed voltage O R for any given secondary voltage.

If the diagram is plotted on squared paper with sufficient accuracy the regulation can be obtained at once from Fig. 2, since

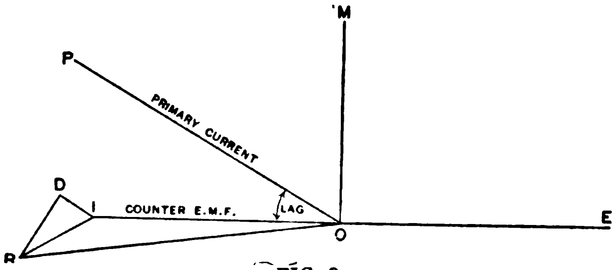

FIG. 2.

when O R is primary impressed voltage, O I is to same scale secondary induced voltage, and may be expressed in per cent. of the former. Deducting the secondary C R drop in per cent., we have the percentage of primary voltage appearing at secondary terminals.

But for greater accuracy it is preferable to calculate the side of the diagram. Let in Fig. 3 the vectors I D and D R be replaced by I J and J R, the vector of primary impedance I R remaining unchanged.

From the known values of primary impedance, C R and reactance, the angle of the impedance triangle is known. The corresponding angle J I R = β of the new triangle is equal to a reduced by the small angle J I D. But this latter angle is the angle of lag between primary current and counter e. m. f. and is readily found from the known values of exciting and full load current. (A tabulation of the lag angle for values of exciting current from 5 per cent. to 20 per cent. is given further on.)

Having found the new angle β and knowing the value of primary impedance, the new vector J R (which we may call equivalent reactive drop) is found as the sine of the angle β and the vector I J (or equivalent primary C R) is the cosine of the same angle.

Having expressed all the values in per cent. of primary voltage for convenience, we now resolve the right angle triangle O R J, taking O R = 100 per cent., R J = equivalent reactance drop per cent., and obtain O J, which is secondary terminal volts per cent. + sec. C R per cent. + prim. equiv. C R per cent. Knowing the last two values, we at once have the per cent. of primary voltage appearing at secondary terminals, and therefore the regulation of the transformer.

As an illustration, the method will be applied to the determination of regulation drop at full load of a transformer on which the following measurements are known. (The measurements of cop-

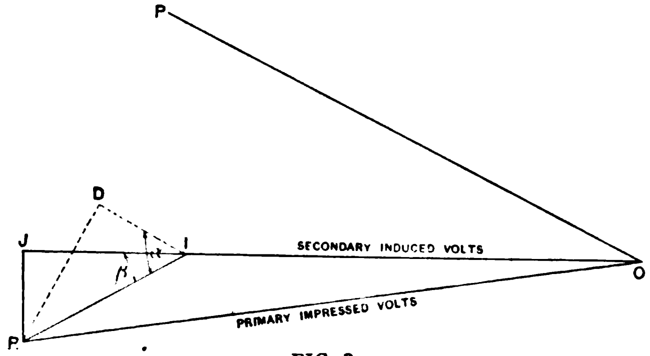

FIG. 3.

per loss and impedance drop are made by means of a wattmeter, the secondary of the transformer being short circuited, as described in Dr. Bedell's paper on transformer regulation.

Capacity of transformer, 2,500 watts; ratio of transformation, 10:1; primary voltage, 1,000—frequency, 125 cycles; copper loss (C^2R), 50 watts; C. R. drop, 2 per cent.; impedance drop, 54 volts = 5.4 per cent.; iron loss, 60 watts; exciting current (no load current in primary at 1,000 volts), .125 amperes.

The lag angle of primary current behind counter e. m. f. line is determined from the relative values of primary exciting current, and primary full load current. For convenience, the lag angles are tabulated below for values of exciting current from

5 per cent. to 20 per cent. on the assumption that the magnetizing component is 80 per cent. of the exciting current. This is sufficiently accurate for all ordinary transformers on frequencies of 50 cycles and above. The value increases, tending toward 100 per cent. with the large exciting currents accompanying very low frequencies.

TABLE OF PRIMARY CURRENT LAG.

Per cent. exciting current.	Angle of lag.
5 per cent.	2. degs.
8 per cent.	3.5 degs.
10 per cent.	4.5 degs.
12 per cent.	5 degs.
14 per cent.	6 degs.
16 per cent.	6.5 degs.
18 per cent.	7.5 degs.
20 per cent.	8 degs.

This table is not correct for frequencies below 50 cycles.

In the case under consideration we have exciting current 5 per cent., lag angle, 2 degs. The total impedance drop is 5.4 per cent., the CR. drop 2 per cent. and reacitve drop $\sqrt{5.4^2 - 2^2} = 5$ per cent.

The primary impedance drop is the resultant of reactive drop and primary CR. drop, which we may take as one-half of the total C R drop. It is therefore $\sqrt{5^2 - 1^2} = 5.1$ per cent.

In Fig. 2 we then have I R = 5.1 per cent.; I D = 1 per cent.; D R = 5 per cent. To find the angle R I D we find what angle has its sine (R D) = $\frac{5}{5.1} = .981$. The angle is 7 9degs. (See angle α Fig. 3.) Deducting from this the current lag angle we have for the angle β 77 degs. J R is the sine of this new angle and is $.974 \times 5.1 = 4.96$ per cent. Similarly J I is the cosine of 77 degs., and is in value, $.225 \times 5.1 = 1.15$ per cent.

To determine the regulation we now resolve the right triangle R O J. R O = 100 per cent.; R J = 4.96 per cent.; J O = $\sqrt{100^2 - 4.96^2} = 99.87$ per cent.

Deducting J I = 1.15 per cent., we have 98.72 per cent. as secondary induced voltage (I O), and deducting again secondary C R drop of 1 per cent. we have 97.72 per cent. of primary applied voltage appearing at the secondary terminals, or a regulation drop of 2.28 per cent.

It is of interest to note here that figuring the regulation of this transformer by the simpler method first described, entirely ignoring the effect of exciting current, the result gives 2.13 per cent. regulation drop, a difference of 0.15 per cent., due to 5 per cent. exciting current. With a larger reactive drop in the transformer, other losses being equal, the difference between results obtained by the two methods would be somewhat greater.

Calculated by Dr. Bedell's method, before referred to, the regulation drop obtained is 2.44 per cent., slightly higher than that by the method above. This is due to the fact that Dr. Bedell's method assumes that the magnetizing current is equal to the exciting current, which is not the case, and also in a slight degree to some other minor approximations adopted in the construction of his diagram.

The percentages of iron loss and exciting current taken in the above illustration are higher than would be found in good modern transformers of any but the smallest sizes, but they have been purposely taken here to illustrate the point under discussion. For the same reason the diagrams are greatly exaggerated. In actual practice the primary current line O P is very nearly parallel with the line O I.

OBITUARY

Stanley S. Stout.

Stanley S. Stout died in Chicago on June 19 after a short illness. Mr. Stout was a patent lawyer and began his career as an examiner in the United States Patent Office. During recent years his practice had been largely in the field of telephone litigation and he had made a large circle of acquaintances in the electrical field.

MECHANICAL

Mechanical Draft.[1]

BY WALTER B. SNOW.

THE substitution of the fan for the chimney as a means of draft production marks a distinct advance in the convenience and economy of steam generation. It is, therefore, fair to assume that a discussion of mechanical draft must be of particular interest to all who are concerned in central station management. Although the advantages of many improvements are to be viewed solely in their direct commercial relation, such is not the case with mechanical draft. Not only does its application insure an evident economic gain, but in both its installation and operation there are certain conveniences which are to be considered as distinct advantages although it may be almost impossible to determine their definite economic values.

Mechanical draft may, in stationary practice, be applied in either of two ways: First, by forcing the air into a closed ashpit, and maintaining therein a pressure in excess of the atmosphere, and second, by exhausting the air and gases from the flue or uptake and thereby creating a partial vacuum which causes a constant inward flow of air in the combustion chamber. The former is designated as "forced draft" and the latter as "induced draft." Under certain conditions a combination of the two methods may be found desirable. The natural result of the application of a centrifugal fan in either manner is to render the draft conditions positive at all times. A fan of the disc or propeller type is entirely inadequate for such work.

On the erection of a chimney the first matter to receive consideration is the foundation. This always represents a comparatively large, and in the case of unstable ground, an abnormally excessive proportion of the expense of the entire structure. A fan on the other hand, is relatively light, requires no expensive foundation, and may in many cases be located upon the top of the boilers. Not only does this vastly reduce the cost of installation, but it furthermore lessens the space required, which is always a definite character in the case of the chimney, but with a fan placed overhead is entirely eliminated.

The portable character of a mechanical draft apparatus renders it not only valuable as an available asset, when it is no longer required in a given location, but makes possible its relocation or arrangement in a manner that is absolutely impossible in the case of a chimney, which must always stand as a monument to a departed industry or an abandoned means of draft production.

The primary duty of the chimney is to create sufficient draft, while its secondary office is to remove the gases and smoke to a proper height for discharge to the atmosphere. The height required for this purpose is almost universally less than that necessary to produce the draft. Obviously, a stack of decreased height and cost will serve the purpose with mechanical draft. In fact, a sheet iron pipe extending but a few feet above the top of the boiler house will in most cases fulfill the requirements.

The steel plate construction which is common to most fans employed for producing draft makes it possible to readily design and build them to exactly suit any given conditions. Such a fan may be arranged to be driven by a belt or by a direct connected engine, as may be desired, may be automatically controlled in its speed to meet the requirements of steam generation, and may be increased in capacity by the simple transmission of more power.

In operation, mechanical draft is both positive and flexible. Its positive character renders its action independent of the weather and its flexibility lends to it that characteristic so lacking in the chimney, the ability to exactly adapt the intensity of the draft as well as the volume of air to the existing requirements. How much those two elements of simple convenience mean in the generation of steam for electric traction work can only be realized by one who has experienced the sudden and immense fluctuations incident to such service. The fan is always at its best, can be instantaneously pushed to its utmost and does not have to wait for hotter fire to produce stronger

[1] Abstract of a paper read before the N. W. Elec. Assoc., June, 1898.

draft. When properly installed, such a fan should be provided with an engine devoted solely to its driving, and the speed of this engine should be so controlled by devices that are readily applied, as to increase its speed in proportion as the steam pressure falls. It is thus possible under all ordinary conditions to maintain practically constant steam pressure and to insure immediate response to sudden demands.

Another feature of convenience resulting from the employment of mechanical draft is to be found in the ability to burn cheap fuels which are almost invariably of small size and require an intensity of draft which is not readily created by means of a chimney. The economic value of this and the preceding features of convenience will be considered as we proceed.

The "smoke nuisance" is in many of our communities receiving the attention that it properly deserves. In practically all devices which have proved successful in the prevention of smoke, improved draft has been a most important factor and the positiveness and intensity of the draft produced by a fan have assured the success, which has attended its application.

We may now turn to the distinctly economic aspects of the installation of mechanical draft and of necessity these must be considered relatively to those incident to the use of a chimney. Employed solely as a means of creating air movement, the chimney is most absurdly inefficient. It may be readily shown that under the ordinary conditions of boiler practice an engine driven fan will move a given amount of air with the expenditure of about one seventy-fifth as much power. This immense advantage of the fan over the chimney may be turned to good account by introducing proper devices for transferring the heat of the gases to the feed-water or to the air supplied to the fire, and the gases may, with fan draft, be cooled to a temperature far below that which could be attained with a chimney without too seriously reducing its draft.

Custom and the expense of high chimneys are, doubtless, responsible for the comparatively low combustion rates which prevail in most steam plants. It may be fairly stated that to double the rate of combustion on a given grate area, it is necessary to make the chimney about three times as high, at a cost, perhaps, five times as great. In the case of a fan the same result could be obtained without even so much as doubling the cost.

Low combustion and evaporation rates are not essential to high efficiency. Within reasonable limits the higher the rate of combustion, the less is the volume of air required per pound of coal. The fire is of necessity deeper, the draft is stronger, and each individual particle of air has increased opportunity to come in contact with the fuel. With a decreased supply of air the intensity of the fire is increased, its temperature is higher, more heat is radiated to the exposed boiler surfaces and more is taken up by the gases, which, because of less ultimate volume, move at lower velocity and thus have more time to part with their heat.

When a fan is employed as a means of draft production it may, at comparatively small expense, be installed of such size as to possess a potential capacity which if embodied in the boilers could only be provided at vastly greater first cost with incident larger fixed charges.

The power expenditure for operating the fans should be practically inappreciable in any well designed plant in which provision is made to utilize tne exhaust steam from the fan engine.

The most direct saving in operating expense, which may be secured by the introduction of mechanical draft, is that resulting from the utilization of cheaper fuel. Such a plant as previously described would, under good conditions, probably, require at least 8,000 tons of high grade coal per year, operating ten hours per day. If a saving of only 25 cents per ton could be effected it would represent an aggregate of $2,000 per year, a pretty good return on an investment of $3,500. But in many cases much greater savings may be brought about. A case in point is that of the United States Cotton Company at Central Falls, R. I., where, with a 1,000 horse power boiler plant, the fuel originally employed chimney draft was George's Creek, Cumberland, costing $4 per ton. With forced draft, a mixture of No. 2 buckwheat screenings and Cumberland is now used, costing $2.62 per ton. The saving has been about $125 per week, enough to pay for the special steam fan in about six weeks.

Other direct and indirect advantages of mechanical draft might be presented, but the limits of the paper will not permit. If it were not for its rough and ready character, the chimney would long ago have been discarded, because of its wastefulness. In the search for the highest efficiency such waste can no longer be ignored and when dollars and cents are concerned, crude methods must give way to those of greater refinement. It is for this reason that the most progressive engineers of the present day are not only considering, but adopting mechanical draft as a substitute for the chimney.

In the discussion which followed the reading of this paper, Mr. Doherty pointed out the saving effected by the use of electrically driven feed pumps. He also referred to electrically driven fans for creating the mechanical draft and said that the latter must be crowded in order to give efficient service. He also discussed the relative economy in the use of economizers and recuperators, and he declared himself to be rather in favor of the latter. He commented highly on Mr. Snow's reference to the prevention of the smoke nuisance by the use of mechanical draft.

Mr. Dow made a few remarks about the advantages of using a thick layer of fuel rather than a thin one, as the former produces the appearance of carbonic oxide and reduces the amount of air enormously. These arguments were refuted by Mr. Doherty, who stated that he has seen thin beds produce considerable carbonic oxide and at the same time a large quantity of free oxygen.

Mr. Cross, the reader of the paper, in the absence of the author, closed the discussion by expressing the opinion that mechanical draft, economizers and automatic stokers might be all right for large central stations, but small stations could make steam just as cheap without any of them, if you count in the interest charges on the extra investment. He believed however, that mechanical draft might decrease the investment.

"Crypton"—Another New Element.

A SPECIAL dispatch from London of June 6, says: Professor Ramsay, the joint discoverer with Lord Rayleigh of argon, has, with the assistance of Morris Travers, eliminated from the atmosphere a new gas, which he calls crypton. The new element is obtained by evaporating large quantities of liquid air. It is transparent and heavier than argon, and like the latter is inactive. It exists in the atmosphere in the proportion of one to 20,000. Its chief lines in the spectrum are green and yellow. The latter is nearly coincident with the helium yellow line, D3.

M. Berthelot has read to the Academy of Sciences, in Paris, a communication from Prof. Ramsay in reference to crypton, from which it was learned that the discovery, like that of argon, was made by the spectroscope.

The discoverers received from Dr. Hampson 750 cubic centimetres of liquid air, which they reduced by evaporation and collected in a tube. A gas was furnished by the residue. This gas was deprived of its oxygen by the help of metallic copper, and of its nitrogen by the action of the electric spark, and of its oxygen after that by a mixture of magnesium and pure lime. This effected, there remained 26 cubic centimetres of gas, which presented, besides a weakly defined spectrum of argon, an additional spectrum till then unknown. It was characterized by exceedingly brilliant lines, one almost identical with D3. The other green line may be compared in intensity with the green line of helium. Its wave length was 5566.3. Another slightly weaker gave 5557.3. The density of the gas was approximately 22.5, that of oxygen being 16. According to the velocity of sound the ratio of specific calorics is 1.666, the same as that of argon and helium. It therefore follows that the new gas is monatomic and constitutes an element.

These facts go to prove that the atmosphere contains a hitherto unknown gas heavier than argon and with a characteristic spectrum less volatile than nitrogen and oxygen and argon. Prof. Ramsay was unable to absolutely determine its position in the periodical. He, however, hazards the conjecture that the pure gas has a density of 40 and an atomic weight of 80, and that it may be classed with helium. The investigations are being continued, and a larger quantity of the gas is being prepared. M. Berthelot, who received a small supply of the new gas in a Fluckyer tube, has verified the existence of new lines by the spectroscope.

Mechanical Draft and Boiler Room Economy.

WHEN one considers the multiplicity of apparatus in a modern central station other than that used for the transformation of mechanical energy into electrical and for the distribution of the latter, and compares their relative efficiencies, it is not at all surprising, but seems rather imperative, that central station men, in convention assembled, should turn their minds to the discussion of steam making and steam using appliances. It is an encouraging sign to see the societies composed of central station men include in their list of papers several dealing with problems other than electrical and which so seriously affect the economy of a central station. One of these is the subject of mechanical draft, on which a very able paper was read by Mr. Walter B. Snow at the convention of the Northwestern Electrical Association and an abstract of which appears on another page. The employment of mechanical draft is one of the many perplexing "improvements" which have as many opponents to depreciate their value as they have advocates to laud their advantages. It is a problem dependent largely upon local conditions, and may be shown to possess advantages when installed at the time a station is built, while it may become a material disadvantage financially and a source of trouble when installed in a central station already giving good results. There are two general methods by which mechanical draft can be secured, namely, the aspirating principle, in which a rapid motion is given to the air to draw it out of the smoke-box, so that the reduction of pressure within the latter shall cause a flow through the grates, fire and tubes to equalize this rarefaction, and secondly, the forced draft-system, in which a pressure of air is caused in the ash pit below the grate bars, so that the air will flow up through the fire, the setting and flues by the excess of pressure which prevails in the ash pit. Since combustion is more efficient, the denser the air is used to effect it, the pressure system seems to offer an advantage from this point of view.

In answer to the question which has been raised as to whether the employment of mechanical draft may in time do away with the chimney, it should be remembered that when the chimney is once built and paid for the draft machine costs nothing to run except the heat which is used for this purpose, and it undergoes little or no deterioration with use. Furthermore, in cities, the necessities imposed upon the power plant to carry the products of combustion high enough up to create no nuisance in its neighborhood compel a height and cost of chimney which make the consideration of mechanical draft unnecessary, since the high chimney must be there in any case. Again, where the plant is so large that the cost of the draft machine becomes considerable, or what is the same thing, the cost of the expensive chimney becomes distributed over a large number of horse power units, the advantages of mechanical draft are not so apparent. It offers, on the other hand, according to Prof. F. R. Hutton, the following distinct advantages: (1) The rapidity of combustion in the fire box is not limited by atmospheric conditions, (2) it is possible to increase the evaporative capacity of a given plant without other change than the velocity of the draft-machine, (3) it is possible to burn inferior, cheaper and smaller sizes of fuel with mechanical draft, because a high pressure can be maintained which will force the necessary air through a compact body of fuel, (4) where high stacks are not made necessary the cost which they entail is avoided, or is offset by a less cost of the draft-machine. The objections to be raised against mechanical draft are: (1) The running cost of the machine, including fuel, repairs and supervision, (2) the machine occupies space which can often be ill spared, (3) running machinery, and particularly that at high speed, such as most draft appliances demand, is rarely silent, is often noisy and is liable to breakdowns which compel it to stop. To weigh these advantages and objections against each other and include in the discrimination the local conditions which will affect the decision is the serious problem with which the central station designer and manager has to deal. In making this decision, however, he should not lose sight of the fact that he may overburden his station with labor-saving devices which if not properly handled and carefully watched may become the most dangerous fuel-consuming devices in his plant. He may place his engineer in the position of the unfortunate wife who was compelled to get divorced from her husband because he insisted on having every new domestic mechanical appliance used in his household for every conceivable purpose. If the managers of central stations would look more to the correct handling of their simple apparatus and see that the engineer and fireman perform their functions efficiently, perhaps there would be no need for the recent statement by the Mutual Boiler Insurance Company that, through bad shoveling nearly $2,000,000 worth of fuel is wasted yearly in the boilers under their control. Let them pay attention to this, and to the economical purchase of the right kind of coal; let them prevent their steam from escaping through leaky joints or their heat being wasted by poorly covered pipes, and they will discover in their boiler-room the truth of the words that "Trifles make perfection, and perfection is no trifle."

Aluminum as an Electrode in Cells for Direct and Alternating Currents.

THE above topic formed the subject of a very interesting investigation undertaken by Mr. E. Wilson, the results of which have been communicated to the Royal Society by Dr. J. Hopkinson. The paper deals with the apparent great resistance which aluminum offers to the passage of an electric current when used as an anode in cells containing, for instance, such an electrolyte as alum in water. In the first series of experiments, with direct currents, cells having aluminum and carbon electrodes and an electrolyte of saturated alum water were employed, and a current of 3.6 amperes and 4.4 volts was passed through the cells. After some time the current was reversed, the time between reversals having been 27 minutes, and the very important point was brought out that the current, when reversal took place from 3.6 amperes, first crossed the zero and acquired an opposite sign, finally coming to zero of the instrument. The experiment was repeated with the same electrodes and an H_2SO_4 solution, with similar results, which have been carefully tabulated. Investigating the effect of temperature upon the potential for a given current, it was found that as the temperature of the cell rises from 13.5 to 70° C. the potential difference falls from 30 to 3 volts, for which the change of resistance will only partially account. It showed that the film which had been formed on the aluminum plate has a high resistance and is affected by the temperature, and that this film is more stable when the positive pole of the charging battery is connected to the aluminum. It is a well known fact, however, that a clean aluminum plate acquires this film when simply submerged in an alum solution in the presence of oxygen without the passage of currents. This film, according to an analysis made by Prof. Herbert Jackson, consists of basic aluminum sulphate.

By far the most interesting portion of the paper, and one which may lead to important commercial results is the one dealing with the effect of the alternating current on the above cells. These experiments were undertaken to investigate the instan-

taneous values of potential and current and to see if aluminum is a valuable metal for use in condensers for alternating currents. Numerous experiments with different frequencies were made, and it was found, among other things, that with the working of these cells the aluminum wears away and the electrolyte evaporates rapidly. By employing large aluminum plates opposed to each other in a saturated alum solution it was found that aluminum was well suited for plates in condensers. The author sums up his conclusions in the following manner: "The effect investigated in this paper takes time to develop, and is not fully developed with alternating currents of frequencies sixteen and ninety-eight complete periods per second. It can be increased by increasing the current density for a given film, and is greatly influenced by temperature. The metal aluminum, with its film, is suitable for use as the plates of condensers, if due regard be given to current density and temperature. It might in some cases be found useful as an equivalent to a metallic resistance." Does this not appear to be a step towards lightweight storage of electrical energy?

Power Transmission Schemes.

THERE is no dearth of power transmission schemes. If they crop up at the present rate, we don't quite see where coal will find any raison d'etre as an industrial factor, for, should all be developed, there will be current enough to run all the machinery in the country and do a little lighting and heating "on the side." The difficulty of such work no longer consists in developing the power, but in developing the customer for it, and the latter point is the one on which many of the proposed enterprises must break. Some of these schemes are away off in the wilderness, and although the power plant may in time constitute a nucleus for other work, dependent upon it, we must confess our preference for projects that already have a dense population settled within the territory of operation. This feature is what makes the Niagara plan so hopeful and tangible, for it has the big, bustling city of Buffalo well within reach and a number of other industrial centres adjacent, as well as a market just at the Falls. This consideration also is one that gives an air of reality, to say the least, to the schemes of the Ramapo Water Company, which not only seeks to furnish water from the Catskill region to the millions of people living in New York and its vicinity, but sees a large opportunity for electrical power transmission from the one thousand square miles of lofty watershed thus to be tapped.

It must be evident to any one who studies the situation that the population seated at the seaboard here must continue to strike further and further inland for its source of water supply, and may even have to tap Lake Erie. But this Catskill project may well be a feasible compromise of long duration and carry with it the generation of abundant electrical current for many years to come. Whether New York can get any of the power, whether, in fact, there would be enough to pay for bringing it here, we are not able to determine, but it is obvious that there are a number of uses and services between here and the Catskills, to all of which the current could be profitably applied, such, for example, as the operation of the West Shore Railroad and other lines through the region, as well as many industries along the Hudson River.

How to Distribute Street Lights.

THAT we have by no means reached the end of developments in street illumination is a fact that is brought to mind again by the interesting article from Mr. Henry Hopkins, which we print in this issue. His data, opinions and conclusions, as those of a highly competent and efficient city official, will receive careful attention. He makes a fine showing for the arc light, and it will be agreed with him that the arc is not liable to be superseded. We would like, however, to see his suggestion of greater subdivision of the arc carried out experimentally. The effect of the small MacIntire enclosed arcs at the recent Electrical Exhibition in this city was strikingly good and must have suggested not only the general feasibility of greater subdivision but the use of the arc in places from which its volume and intensity have hitherto debarred it. There should be no need to "chink in" with Welsbachs anywhere. As Mr. Hopkins says, "the locality should govern the system," and if a big arc light does not meet the conditions, an electric lamp of some other size that does answer should be readily available.

Motor Fans on Trains.

IN our issue of June 16 Dr. Margaret A. Cleaves made the interesting suggestion that it would be a good move on the part of railroad companies to put fan motors in their passenger cars in the summer time as a means of keeping the air fresh and pure. By a curious coincidence, the announcement is now made that the Baltimore and Ohio Southwestern Railway officials have solved the problem of cooling sleeping cars in stations at night. At Cincinnati, Louisville and St. Louis this line has sleeping cars placed in the stations at 10 p. m., which do not depart until after midnight, and in order to make them comfortable and cool it has placed 16-inch electric fans in each end of the sleepers, thus removing the heated and impure air from all parts of the car. The fans have been in operation about two weeks and have been the subject of many favorable comments from the traveling public. This is certainly a step in the right direction and a piece of judicious enterprise worthy of general imitation on all the railroads. Why should not all cars be sweetened and freshened in this way before taking on passengers? It would not be very expensive; in fact, it might more than pay for itself in the inducement thus given to ride rather than avoid, as one now does, the hot, stuffy, smelly cars that are so uninviting. Perhaps the innovation could be limited to certain cars where an extra payment is already asked. We can hardly be mistaken in supposing that it would be welcomed by a great many. Dr. Cleaves' idea of fan motors on the cars while in motion is not bad. It would enable one to close the windows that now let dust and cinders in so freely, as the fans would keep the air circulating. The coming of electricity for traction purposes will soon render all these improvements far more possible and feasible than they now are.

Battlefield Communication.

IT will be interesting to see how the present campaign in Cuba tests the utility of various means of communication on the battlefield and how far our Signal Corps has perfected its system and apparatus. We are glad to note the active recruiting that has gone on for the signal service ranks, but these new men have to be broken in, and what we are all concerned with just now is the activity in the neighborhood of Santiago de Cuba. In such a country as the eastern end of Cuba, with high mountains, dense forests and few roads, lines of communication are even more necessary than they would be in an open district of plains, and we opine there is plenty of work cut out for the Signal Service Corps. The tropical forest is not kindly disposed to aerial circuits, the tropical rainy reason is not the best for high insulation, and the demands on vigilant inspection and maintenance will be heavy. In fact, a better opportunity to dispense with wires and try the Marconi system from mountain top to mountain top could scarcely be found. There is also a good chance to test the serviceability of army balloons and even of homing pigeons, as well as searchlight signals by night—any means, in short, that will keep a commanding officer in touch with his men and informed of all that is occurring. We hope to record for General Greely, Chief Signal Officer, and for the whole corps a large amount of invaluable work.

Electricity on Steam Railroads.

ONE of the papers at the recent meeting at Saratoga Springs of the American Railway Master Mechanics' Association was by Mr. Brangs, the electrical engineer of the Delaware & Lackawanna R. R., on the subject of the application of electricity to steam railroad traction. It was an excellent review of the subject, the speaker showing himself to be in favor of main-line use of electricity, and he made the statement that a ton-mile can be operated by the electric system for less than one-half the cost for fuel, and that the total cost of electric power, including all power station expenses, would not exceed three-quarters the cost of coal for the steam locomotives. A Mr. Hibbard, of Minneapolis, in commenting on the paper, said he thought that electricity was still limited to suburban work, but added: "For suburban service I believe it is to the shame of our steam railroads that they have allowed the electric trolley companies to get ahead of us. * * * It is a shame that we have permitted the electric railways to get almost all the passenger traffic." That is a frank admission, to say the least, but the Consolidated Railroad has shown up at Hartford how the steam companies can hold their own if they adopt electrical methods, with all the increased flexibility and better service that such methods imply.

ELECTRIC TRANSPORTATION

Electric Street Railways in Baltimore, Md.—II.

BY C. B. FAIRCHILD.

THE BALTIMORE CONSOLIDATED RAILWAY COMPANY.

THIS company was formed by the union of the Baltimore Traction Company, the City and Suburban Railway Company, and other smaller companies. The aggregate trackage is about 200 miles, on which 883 cars, open and closed, are operated, with about 1,000 car employés. Mr. Nelson Perin is president, and William A. House is vice-president and general manager. All the lines are now operated by electric power, the first electric installation having been made in 1892, when four cars were put in operation. The two cable lines belonging to this system were transformed in 1896, but the old cable tracks have been retained. The tracks of the cable construction are standing up remarkably well under the heavy electric cars, showing that the original construction was exceptionally well done.

The rolling stock of the cable road was mounted on trucks and equipped for electric power. Since the change from cable to electric cars, it is estimated that the cost for operating per car mile is 25 per cent. less than by cable power. Two of the old cable power stations are idle, and some of the engines are for sale.

A variety of motors and trucks are found, owing to the different equipments on the original line. The trucks include those of the Lord-Baltimore type, manufactured by the Baltimore Car Wheel Co., and those of Brill & Bemis manufacture. The motors include the G. E. 800 type, W. P. 50's, and Westinghouse No. 3. Sixty new nine-bench open car equipments have recently been bought, which were made by the Brownell Car Co., of St. Louis. These new cars are mounted on Lord Baltimore trucks, with wheels by the same makers, and are equipped with Westinghouse No. 49 A motors.

In connection with the operating department, three trouble stations are conveniently located, which are equipped with tower wagons and wrecking tools, and are provided with an automatic signaling system.

POWER STATIONS.

There are three stations in which current is generated, having a total steam equipment of 7,350 h. p. Two of the stations are equipped with McIntosh & Seymour engines and General Electric generators, the other with Westinghouse generators and engines. The Pratt street station is the largest, and is one of the most modern and model stations of the country. The building is of brick and of ample proportion, the engine room being 192 by 84 feet, and the side walls 42 feet to the eaves, and capped with a high monitor roof.

The electrical equipments, including the generators and switchboard furnishings, are all of the General Electric manufacture, while the engines are of the McIntosh & Seymour make, and all are tandem compound condensing. The units include four belt driven machines and two direct coupled. Of the former the generators are each of 500 k. w. capacity, and the engines each of 800 h. p. The direct coupled generators are each of 800 k. w. capacity, and the engines 1,200 h. p.

The auxiliary equipment consists of a direct coupled booster of 100 k. w. capacity, which is driven by a 250 h. p. engine. This machine raises the tension on a particular line 125 volts, or to 675 volts, as the station output is under a tension of 550 volts. There is another auxiliary equipment, consisting of a small 200 k. w. railway generator, and a 100 k. w. booster, which are set tandem, and are driven by a double belt from a 250 h. p. engine.

The switchboard is of black marble, and is built half on each side of a corner angle against the station walls. The belt driven generators have the openings at the end of the main shaft bearings covered with glass; the glass is mounted in a circular brass sash, which is fastened by screws through holes drilled into the edge of the bearing. The glass prevents the dust from entering the bearings while it allows of the necessary inspection.

A peculiar feature of the large engines is a small supplementary shaft mounted in line with the main shaft, but which is driven by a drag link from the crank pin. On this shaft are mounted the eccentric rod and a small flywheel, which contains the governing mechanism. A small oil pump, operated by a pin in the end of the main shaft, serves to deliver the oil to the main bearings; the supply being taken from a tank inside the bearing pedestal. The station is equipped, however, with a home designed automatic oiling system by which the oil is supplied to all wearing contacts on all the machines except to the main bearings and the cylinders; the latter are oiled in the ordinary manner. The oiling device includes a circular air tank, which is mounted slightly above the cylinders, and which has a capacity for a 24-hour supply. From this small tank small brass pipes lead to the parts that require oiling. These tanks are filled automatically from a large boiler tank, which has a capacity for about 600 gallons, and which is located in the basement, and from which the oil is forced by air pressure. Located beside the tank is a filter, consisting of an iron vat having two compartments. The waste oil from all the machines is led by pipes to the first compartment, into which it drains through a fine mesh copper sieve. Near the surface of this tank are two rows of small steam pipes containing live steam, and which serve to raise the temperature of the oil near the surface, thus reducing the specific gravity, and causing the water and dirt to sink to the lower portion of the tank; while the clean surface oil flows over a partition into the second compartment, from which it is pumped into the storage tank.

Any supply of new oil that may be required is introduced into the second compartment of the tank. The water and waste are drawn off from the bottom of the first compartment, which is also provided with a water gauge to indicate the character of the contents. A Boyden air pump, located against the wall in the engine room, supplies the necessary pressure for forcing the oil into the auxiliary tank, and for blowing out the service pipes when necessary, and also provides an air blast for cleaning the generators. A marble stand and basin is also conveniently located in the engine room, which is provided with two faucets from one of which the cylinder oil is drawn, and from the other such machine oil as may be required for special purposes; the oil in both being under air pressure. The automatic oiling device prevents a waste of oil, permits of cleanliness about the room and leaves little work for the attendants.

In this connection it may be noted that the engineers and attendants, as well as the firemen in the boiler room, are all required to wear a uniform while on duty, which, as well as the hat, are made from white duck cloth. The regulations require that the uniforms be changed for a clean suit every Sunday morning, the theory being that if the men learn to keep themselves clean they will take more pride in keeping the machinery in fine condition.

The economic features of the boiler room are not less interesting than those in the engine room equipment. The steam is generated in five batteries of boilers, each of 750 h. p. capacity, and which are of the Campbell & Zell type, and are fed by Roney mechanical stokers; all the water and steam pipes are provided with Chapman gate valves. A coal and ash conveyor is provided, which is driven by a 20 h. p. engine, and travels in a continuous circuit beneath the ash pits, up the side walls and across beneath the roof of the building. This conveyor serves to deliver the coal to the storage tank above the boilers, and to remove the ashes and elevate them to a bin from which they are readily drawn through chutes into carts. The coal, which is George's Creek "run of mine," is delivered on scows in a slip just across the street from the station. It is elevated and crushed, and delivered into the storage tanks by the conveyor.

For firing, the coal is first drawn into a small hopper by which it is measured, and where it is moistened by a spray that is turned on as the coal flows into the hopper. The opening of the traps and the regulation of the spray is done by valves and a long lever from the floor of the fire room. Each hopper is provided with a swinging chute by means of which the coal is easily distributed to the long hoppers above the grate bars. In the process of filling these hoppers, one attendant swings the chute by means of a chain and pulley block while the other operates the trap lever. The coal being moist prevents dust, and it also causes the charge to coke on the grates, which prevents its sifting through before burning. A staff of two men is all that is required to fire all the boilers, while a third man is sometimes employed for cleaning up.

The company employs an expert chemist, whose duty it is to analyze a specimen of each scow-load of coal, and also each purchase of oil. Water for steam purposes is obtained from the city mains, while that for condensing is drawn from the slip. An artesian well, 100 feet deep, supplies water for washing floors, wetting the coal, and other purposes, but it is not sufficiently pure for steam purposes.

The station is under the direct supervision of Mr. P. O. Keilholtz, electrician and mechanical engineer, and he also has charge of the overhead construction.

REPAIR SHOPS.

The main car shop occupies a large one-story building formerly employed as a car house. The different departments are systematically arranged, and are convenient for access from one to the other. The main floor is provided with a number of pits which run the full length of the building. To the right of this are the machine shops and blacksmith shop, which are separated from each other by a partition; and to the right of these is the winding room, separated from the others by a glass partition. An electric transfer table, located on a cross track in the rear, serves to place cars on any track or in the blacksmith shop. Curves from each house track connect with the main track in front of the building.

The woodworking machinery consists of a band saw and a "Universal" woodworking machine made by M. B. Tidey, and is placed near the front of the main floor, being driven by an electric motor from shafts located under the floor. Over a portion of one of the pits an elevated track is provided, on which run four trolley hand hoists of the Yale triplex type, and so arranged that when a carbody or truck is lifted, it may be run off in either direction. The walls of the pit are of brick, and on each side is a ledge, which provides a track for an armature lifter, which can be run back and forth the length of the pit, and which is operated by a screw. One corner of the main floor is devoted to fender repairs, and two men are constantly employed on fender repairs. The fenders are of home-made design, and are made with pipe frame and rope netting, and fold and turn up against the dash. The wheel guard was also designed by the master mechanic, and is in the form of a scoop fender, so adjusted to the brake mechanism that it dips down to the paving when the brakes are applied. The fenders and guard are both efficient, and the company would continue to use them for their own protection were the ordinance requiring them abolished. There are four blacksmith forges and the tools usually found in shops of this character. A small electric motor drives the fan blower for the fires. A machine for grinding flat wheels occupies a part of the blacksmith shop, and is driven by power from the machine shops; on this machine hollow emery wheels are employed, and it is claimed that considerable saving is effected by grinding the flat wheels.

The journal boxes proper are made of cast iron, the castings being purchased from a local firm. These are finished in the machine shop and are babbited with a very thin lining of metal, which is frequently renewed. Formerly a box entirely of babbit was employed and the metal remelted when worn; but it was found that there was a limit in the number of times the material could be melted, so the cast box was substituted. These are babbited over one end also, so there is practically no wear on the box proper.

The tool equipment of the machine shop is very complete, and consists of five drill presses, five lathes, a shaper and a turret headed lathe. The largest of the drill presses has several attachments for special work, and with some of the others was manufactured by the W. F. & J. B. Barnes Co., of Rockford, Ill. There is also one drill press made by the New Haven Mfg. Co. The shop is equipped with overhead trolleys and hand hoists, together with castor trucks for the convenient handling of material. A babbitting table, with crucibles for melting the metal, and mandrils and presses for holding the journal boxes is arranged on one side of the shop, and every department is so arranged that all the work goes on under the direct inspection of the foreman. Power for operating the shop is derived from an electric motor. The winding room is equipped with the usual tools and appliances for repairing armatures, winding field coils and making commutators, and is in charge of an experienced foreman. From eight to ten hands are employed in this department.

PARKS AND PLEASURE RESORTS.

The Consolidated Company has given special attention to the development and equipment of parks as summer resorts, and now has seven delightful resorts, containing from 34 to 75 acres each, and provided with many attractions, including a scenic railway, dancing pavilions, a riding gallery, boating facilities, ball grounds, tennis courts and provision for other popular games. The largest park, and the one having the greatest natural attractions, is known as Gwynn Oak Park, which is well wooded with native oaks, and has quite a stream of water with an attractive fall, around which are arranged rustic seats; this park is about seven miles from the city, and is reached by two of the company's lines.

DISCIPLINE.

The general manager, Mr. William A. House, refers with a great deal of pride to the economy resulting from the establishment of a board of investigation, the personnel of which includes the general manager, claim agent, superintendent of transportation and the division superintendent of any line on which an accident may have occurred. All complaints and accidents are investigated by this board, and all penalties and discharges are made subject to a majority vote. Officers specially designated are furnished with written statements and such witnesses as they are able to obtain, and a fair and careful hearing is given in each case, without partiality, which insures justice being done to all parties. A report made by the general manager shows as the result of the work of the board and the rigid manner in which accident cases are investigated, that the losses from accident charges during four years following 1893 were to a remarkable degree less than for any preceding year; for instance, the decrease in 1896, as compared with 1895, was 18 per cent., and was over 32 per cent. less than in 1893, the year in which the heaviest losses occurred, although the mileage in 1896 was over 23 per cent. greater than in 1893. In engaging new men a deposit is required, on which the company allows interest. Motormen after being under instructions on a car for seven or eight days report to the master mechanic, who examines them and gives such additional instruction as they may require, with simple illustrations as to why certain regulations, as to handling the motors, are required. They then go into the machine shop for three or four days and are coached by the foreman, who reports them to the master mechanic when proficient, and they are put on the extra list.

In the purchase of supplies, the company patronizes the local dealers to a considerable extent. The wheels, as before noted, are purchased from the Baltimore Car Wheel Co.; mechanical supplies from Jno. Brown & Sons, and some of the electrical materials from the Southern Electric Co.

Trolley Rights in Connecticut.

The Connecticut Supreme Court of Errors has handed down a decision in the New Haven County case of the New York, New Haven & Hartford Railroad Company against the Fair Haven & Westville Railway in favor of the steam company. The decision acknowledges the claim of the railroad company for damages for the crossing of its tracks at grade by the trolley road on Bridge street, near Belle dock, in New Haven. The steam road secured a temporary injunction in 1894 from Judge Hall restraining the electric road from making the crossing, but the injunction was subsequently dissolved. Another injunction was obtained from Judge Wheeler and this was also dissolved. After the hearing on the facts the case went to the Supreme Court, and the decision of that court notes a difference from the general ruling that an ordinary trolley line in a street is not an additional servitude of the adjoining property-holders. Accordingly, unless the trolley road pays damages to the steam road, the latter will have the right to prevent the crossing of its tracks at grade. Since this suit was begun the Legislature has passed a law prohibiting the establishing any more grade-crossings of steam and electric roads.

AMERICAN ENGINE COMPANY, of Bound Brook, N. J., have just taken an order from the Northern Electric Company, of Baltimore, Md., for two cross compound engines, one of 350 h. p. and one of 450 h. p. The American Engine Company have just installed a 350 h. p. engine in this plant, and report themselves as otherwise very busy indeed on all classes of work.

The "X" Rays and Their Safe Application. Destruction of "X" Ray Infections by Electro Sterilization.[1]

BY J. MOUNT BLEYER, M.D., F.R., A.M.S., LL.D.

DISCOVERIES of the properties of the X-rays go on at a rapid pace and the scientific world is watching with the closest interest the experiments that are being made from their different aspects to determine the effect of these rays upon the human body. Since their discovery and their application in medico-surgical work reports soon startled and spread throughout the profession and lay public of a grave danger accompanying the use of these X-rays, owing to the fact that they produced so-called virulent burns by exposure to them.

Records now hold among their files many cases—differing in degree, and some have proved fatal from a lingering exposure to them. Even records tell us of a recent murder trial in this State in which the chief question arose—whether the physician who made this X-ray exposure upon a patient was guilty of an act of negligence from which death followed.

Let me say at the outset of my remarks, from what I gathered from my experimental work, that all your timidity in their future application can be allayed. I concluded that if the X-rays are applied under certain precautions and the proper apparatus used, no such conditions can be possible. I speak now from the actual employment of these rays daily to the chest wall for the aid in gaining early diagnostic signs of tubercular and other allied diseases if present.

This investigation gives me the right of an opinion, and I freely make it before you, showing how we all have fallen into that fallacious position by calling this phenomena as produced by these X-rays, burns, when they are nothing less, nor more than an inoculation. Now that we know how to remedy the dangers connected with their use and how best to avoid repetitions from recurring, and if they occur, whether the physician or who so applied them, is to take the blame if the proper precautions as in any surgical operation are not observed. All these facts I shall refer to in a few moments.

Let me eliminate from your minds that an X-ray application or the use of its photography is a dangerous procedure either on a long or short exposure. If this force is applied and handled by skilled hands and with suitable mechanism, there is absolutely no atom of fear in producing this phenomenon of inoculation known as X-ray burns.

This inoculation is due, according to my observation from a series of experiments to several physical effects produced by the generation of these rays and the general conditions present. It is a known fact that the use of the Ruhmkorff coil in connection with the generation of these rays, is an apparatus which gives an exceedingly high electromotive force and amperage, and therefore such high discharges when exhibited, produce certain physical conditions surrounding the atmosphere of the patient or person who is exposed to these X-rays. To sum up these physical facts, we find that this high discharge is leveled against the subject—carrying with it from the surrounding septic atmosphere certain particles floating therein, also surcharged with bacteria and foreign material upon the clothing and skin of the patient which are at all times present setting up sometimes infectious, and at other times an inflammatory condition from these forced driven septic materials under the skin exposed to this phenomenon.

This in flammatory or inoculated condition is the result of all these facts which I came upon during my crucial experiments and can be avoided without any difficulty now on the part of the operator by the adoption of a few rules gleaned from my practical experience which I shall give in the summing up of my remarks.

I now bring before your notice a few most important facts which are also highly corroborative directly within my own investigation. Those facts cannot help being appreciated at this moment, as they come also from several late observers who studied the question of burns, due to fire and hot water, etc., and the causes of death therefrom.

We already know that many deaths are due to burns produced from other causes than by the X-rays. This fact has puzzled scientists to account for deaths which occurred among persons suffering from other burns, even where the injuries received seemed wholly inadequate to produce fatal results. The havoc caused by skin diseases might be much greater and a far larger surface of the skin attacked, but generally a cure could be effected, whereas in the majority of cases of severe burns the end would be fatal.

That the X-ray burn always appears many days after the application of this force or light to a part of the body and does not show absolutely any early manifestation, as minutes or hours thereafter, but days elapse, even as late as eighteen days thereafter. These X-ray burns begin with a painful dermatitis slowly and symptoms resembling burns from heat or scalds. It is therefore that from the very outset and conditions the difference is apparent.

How should we avoid this dangerous condition in the application of the X-ray?

To sum up in a few clauses the whole matter, let me say the following, viz.:

Above all supplant the static machine for the Ruhmkorff coil. This form of electricity or energy has not the physical properties of carrying foreign material into the depths of the tissue so readily as the other current. Static electricity gives only the high voltage with low amperage, while the other is productive of both high forces, making it an unnecessary and dangerous appliance.

All parts to be either photographed or examined by means of these X-rays should have all clothing removed therefrom, and washed with an antiseptic solution or so prepared as if a surgical operation is to be performed. Also a room which is free from infectious material as possible, should always be made ready, or specially appointed for the purpose. Those are the cardinal rules and must not be deviated from in order to avoid a dangerous inoculation or poisoning.

Shoul. such an X-ray inoculation occur, from unforeseen causes or otherwise, sterilization of the affected part by means of electrolysis is the safest and quickest specific known to me—with the amputation of all loose tissue surrounding the parts. I found in my early work as far back as May, 1896, when I had been as unfortunate as others to inflict several patients with these inoculations (burns) that something more was present to deal with than an ordinary electro dermatitis. Experimental study of this question soon elicited facts that brought me to the discovery of the following remedial agent which I commend to your notice. Electrolysis or sterilization of the parts is a specific. The current decomposes all the infected material and changes them into some other non-poisonous compound thereby relieving the system of poisonous products. This is accomplished by placing such parts of the body into a salty solution of distilled water and connecting the electrode with the negative pole of a galvanic battery with a mil-ampere meter. The positive pole may be placed on any convenient part of the subject, vessels of porcelain, wood or glass are best. The strength of this current should average 5 mil-ampere to a square inch of surface to be sterilized—lasting at least one-half hour; after that time the polarity should be reversed for 5 to 10 minutes in order to set free the chlorine which will again react on all the external and internal exposed surface. Accurate measuring by means of a mil-ampere meter with the use of such current must be strictly adhered to—as serious conditions will arise unless one knows the exact amount of current passing and so as to judge the exact quantity of chemical action, thereby controlling its destructive effects, which if are not known will do serious injury to healthy surrounding tissue.

I know of no more satisfactory and scientific methods in the treatment of these X-rays wounds, and in fact in all deep and superficial wounds and poisonings, than sterilization by electrolysis as advocated in my method as here stated. All wounds with pus should first be drained by incision, before the above procedure is undertaken. I must also state in my recommending sterilization by electrolysis to those that hereafter apply it, they should at least be acquainted with the fundamental principles involving electro chemistry. Good judgment is necessary as

[1] Read before the Medico-Legal Society (Psychological Section), May 26, 1898.

much damage can be done if proper precautions are not observed. The time of application must be always left to the discretion of the operator, especially in deep seated conditions. Reapplications can be always resorted to. There are no contra indications for this treatment by electrical sterilization to any class of infected wounds and skin diseases presented to surgery. However, each case must be treated upon its own merits. After such treatment protective dressing of simple kind is necessary to keep the parts from further infections. To small wounds and infections a sponge electrode to suit the size, well saturated with salt solution, is a rapid way of applying electro-decomposition.

I bring my new and novel investigation before your notice for the first time in the history of antisepsis and hope that it will find its way into general surgery with as much and better satisfaction than the heretofore methods employed and give as good account of itself as it has in my hands.

This work has been the outcome of my early results obtained from the experiments and treatment of tuberculosis and other inflammatory diseases of the lungs, etc., which still occupies my time, already with most fruitful results.

My investigations brought me to a most important point, and that is that all microscopic crevices are cleaned of bacilli, their products, and pus cells, where in the use of antiseptic solutions, etc., a mere coating is effected therefrom and always liable to a reinfection. This form of sterilization does not absolutely admit of such a condition, as destruction takes place instantaneously by electro chemical decomposition also by reversing of the polarity of this current; these microscopical crevices are again closed completely by its electro dynamic action.

Electro sterilization must, therefore, be highly recommended as a prime antidote also to all kinds of stings, dog bites or in fact to even venomous wounds produced by serpents. The current should be applied a much longer time than for ordinary cases.

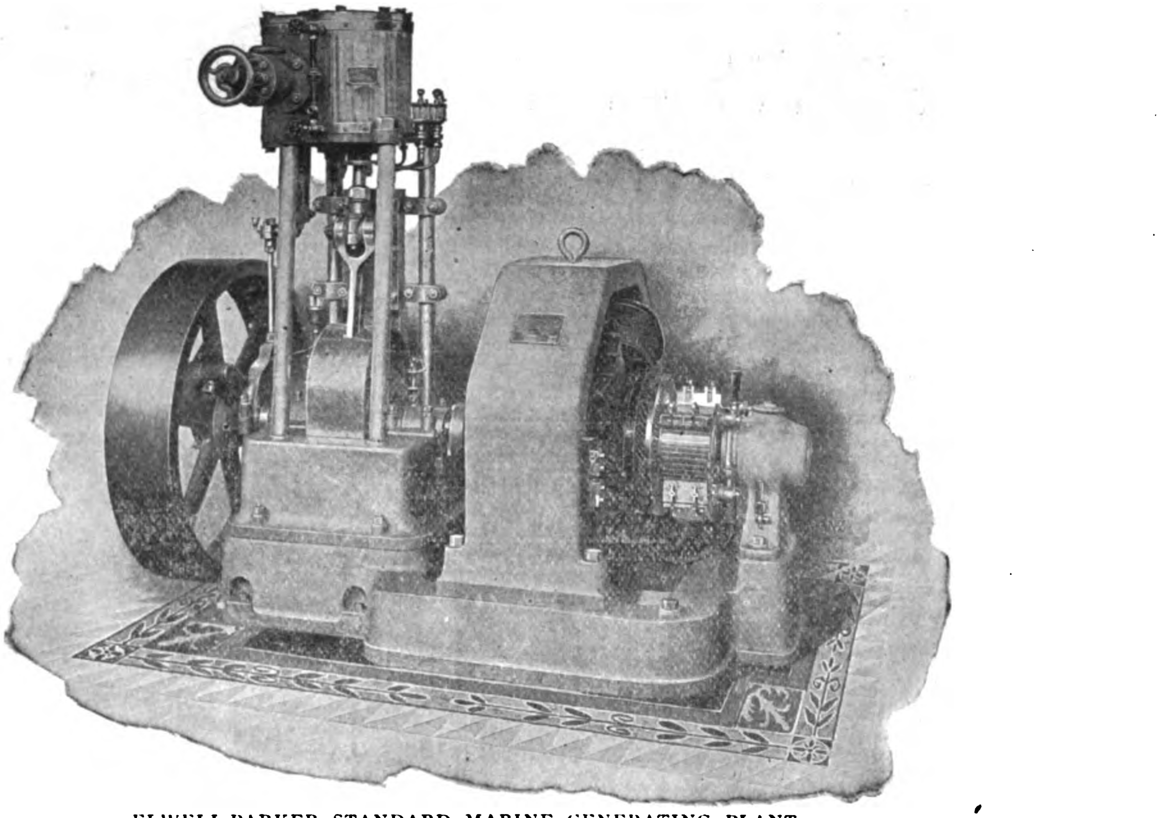
PULASKI, VA. The Pulaski Telegraph and Telephone Company has a capital stock of $24,000, 100 subscribers, a board with 140 drops and a number of toll lines. The apparatus has been built chiefly by the Telephone Manufacturing Company, of Sumter, S. C. Mr. B. Laughan is president and general manager, and D. D. Hull, secretary and treasurer. Rates are $15 a year, payable quarterl yin advance, and 10 cents is the toll rate.

NEWS AND NOTES

Elwell-Parker Standard Marine Generating Plant.

We illustrate and describe herewith the standard marine generating set recently brought out by the Elwell-Parker Electric Company of America, Cleveland, O. This apparatus has been developed by years of experience of the requirements in this class of machinery when used under the exacting conditions that prevail on shipboard. These sets are manufactured in sizes from 5 k. w. to 40 k. w., and, although designed, as we have noted, for special marine work, their compactness and satisfactory results have commended them strongly for stationary isolated installations in various classes of work on shore.

The dynamo is designed for a minimum weight, and to run sparklessly without any overheating. All connections are easily accessible and any parts that need adjustment or renewal are so disposed as to make the most convenient arrangement.



ELWELL-PARKER STANDARD MARINE GENERATING PLANT.

The engine is designed to be very open and all parts are made to be readily accessible. The bearings are extra large, and the oiling arrangements are such as to secure continuous oiling with the minimum of attention. The whole set is rigid and strong, so as to be proof against the jarring to which it is so much subjected on shipboard in rough weather.

The shaft has a coupling between the engine and generator so that each half of the set shall be, as it were, practically independent of the other half. The outboard bearing is self-aligning, self-oiling, removable and made to gauge so as to be interchangeable. A considerable number of these sets have been in use for some time on the lake steamers and have always given the most satisfactory results.

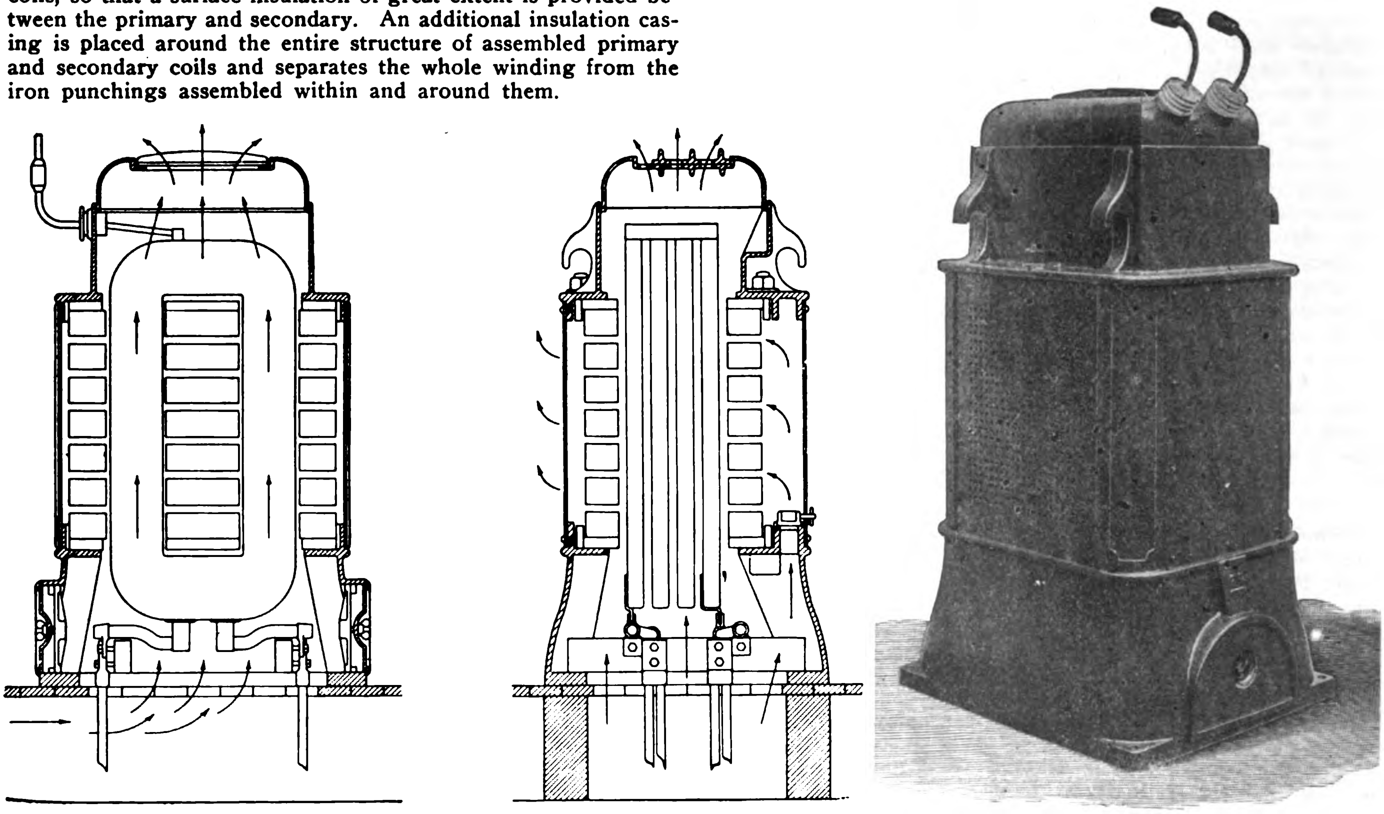
The accompanying cut shows the 10 and 20 k. w. sizes. The 10 k. w. size runs at 450 revolutions, the 15 k. w. at 400 revolutions and the 20 k. w. at 350 revolutions per minute.

Brooklyn, N. Y.—D. T. writes: "I should find it very hard to get along without the Engineer."

G. E. Air Blast and Natural Draft Transformers.

TWO methods are employed as standard practice by the General Electric Co. in the construction of its large transformers. In the "Air Blast" type the current of cool air is forced upward through the core and windings. In the "Natural Draft" type, the coils and iron are so proportioned and placed that large surfaces are exposed, and the temperature kept within safe limits by the natural circulation of the air.

The air blast type is designed for continuous operation, large output and high potential. In this type, the windings are subdivided into numerous independent coils each separately and heavily insulated. With such subdivision the voltage generated in a single section is low even in transformers wound for a voltage of 15,000 to 20,000 volts, and the numerous air ducts between all the coils which this subdivision allows, in addition to the spaces in the iron lamination of the core, limit the rise in temperature to a few degrees only above that of the active cooling air current. The coils are wound with flat copper conductors, cemented together by an insulating compound before the exterior insulation is applied. The method of winding and insulating produces a strong coil which will successfully resist any tendency of the conductors to vibrate. The use of rigid coils is important in large transformers since the magnetic force tending to move the conductor is great; and vibration abrading the insulation might consequently be set up. The primary and secondary coils are assembled in small intermixed groups with air spaces between the coils, and between every adjacent primary and secondary section are solid insulating diaphragms, which completely encase the primary winding except at either end of the core, necessarily left open to allow the air to circulate freely. At the end, however, the diaphragms project far beyond the coils, so that a surface insulation of great extent is provided between the primary and secondary. An additional insulation casing is placed around the entire structure of assembled primary and secondary coils and separates the whole winding from the iron punchings assembled within and around them.



G. E. AIR BLAST TRANSFORMER IN PERSPECTIVE AND SECTION.

The insulation in the primary coils will withstand an insulation test at the potential of operation. Another equally heavy insulation is on the secondary coil. The diaphragms between the primary and secondary coils will also withstand the primary potential. Entirely neglecting, therefore, the additional insulation due to the double air duct between the primary and secondary windings, the method of insulation employed assures a factor of safety of at least three. The insulation test between the high

G. E. NATURAL DRAFT TRANSFORMER.

potential windings and the core is made at a voltage equal to twice the rated potential. A similar test is also given the insulation between the primary and secondary windings.

The cooling current of air is obtained from a motor-driven blower and is forced from below through separate paths at right angles to each other, vertically through the windings and horizontally through the core. The admission of air is controlled by shutters at the top and at the sides of the transformer. The

power for the blower seldom exceeds one-quarter of one per cent. of the total capacity of the transformer, and in most cases is much less, frequently not more than one-tenth of one per cent. It is considerably less than that which would be required to pump oil through an oil-cooled transformer of the same capacity.

Air blast transformers are used on 15,000 volts potential or under and are constructed for higher potential when necessary. Owing to the attention given to the electrical design, the quality of the material used and careful workmanship, the efficiency under full load and partial load, determined under commercial operation conditions, is extremely high. The regulation on both inductive and non-inductive loads, similarly determined, is remarkably close—an important essential when incandescent lamps and motors are operated from the same transformer. Calculating the temperature of the interior of the air blast transformer by the rise in resistance of its windings, the rise in temperature is guaranteed not to exceed 40° C. above that of the surrounding air. Over 100,000 h. p. in these air blast transformers have been installed, and no record yet exists of a burn-out due to heating or overload.

In the "natural draft" transformers the dissipation of the heat is obtained by a natural circulation of the air around the coils. The essential parts of this transformer resemble those of the standard type H. transformer. The core is formed of two upright legs on which the coils are wound. These are joined together by two yokes which complete the magnetic circuit. The transformer proper is surrounded by a corrugated iron case and rests on a substantial base of cast-iron. The cool air enters from below and in passing through the transformer absorbs the heat and ascends, finding easy egress through the hood at the top.

Natural draft transformers of large capacity are much more expensive than similar sizes of the air blast type with air blast outfit, but for moderate capacities the costs per kilowatt of the two types are more nearly identical. The capacity required, together with the particular conditions of the installation, determine when the two types can be furnished at an equal cost, and in such cases the natural draft type is preferable on account of its greater simplicity. Natural draft transformers are built in sizes ranging from 5 k. w. to 200 k. w. They require no attention no blower outfit and may be located in any convenient place. The standard pressures for which these transformers are wound are 10,000 volts primary, and 3,120 volts or under, secondary.

Pelton Water Wheels at Auburn, Cal.

The Pelton Water Wheel Company have been awarded the contract for the hydraulic work of the new plant of the Central California Electric Power Company to be installed at Auburn, Cal. This station is to include two 43-in. wheels, to run under 200 feet head, at 300 revolutions, and develop 800 h. p. The wheels are to be direct connected to a 500 k. w. Westinghouse generator, which is to be electrically coupled to the generators running the Newcastle station of this company, six miles distant, and the power transmitted to Sacramento over the same pole line. The entire distance from the Auburn station is 34 miles.

The interesting features of this plant consist in running two stations so far apart in parallel; also in the double use of the water, it being the same as supplies the Newcastle station six miles lower down. With the rapid fall of many mountain streams, power can thus be multiplied indefinitely and generally within reasonable limit of transmission.

Niagara Power in Buffalo.

As soon as the necessary electrical apparatus and machinery can be obtained and installed the Urban Roller Mills, of Buffalo, will be operated by Niagara power. Steam power is now used. Had it not been for the delay of the makers of the electrical machinery, the mills would probably now be using the current from the Falls, but the demands of the Government had to be met first. However, it is thought the end of July will see the mills electrically operated. The main motor of the plant will be of 400 h. p. capacity, and it will be direct connected to the main shaft of the present system, it having been found possible to use the main part of the present system of shaft and pulleys in the mill. This motor will run all the machinery of the mill, with the exception of that of the grain elevator and merchandise department, and in these cases separate motors will be applied. In all, about 500 h. p. will be used, and a most efficient service is expected in all departments.

There is a good probability that Lockport will soon be in the enjoyment of electrical power transmitted from Niagara Falls, the transmission line, in all likelihood, following the line of the New Buffalo and Lockport railway from the Tonawandas. Lockport has about 16,000 inhabitants, and is quite a manufacturing point, but the power supply is anything but satisfying, as the water for power purposes is taken from the Erie canal, a State possession. It is thought Niagara power can be sold in Lockport for from $40 to $50 per horse power, which figure would probably induce several companies to use it, as the service would be constant for twenty-four hours in a day and 365 days a year.

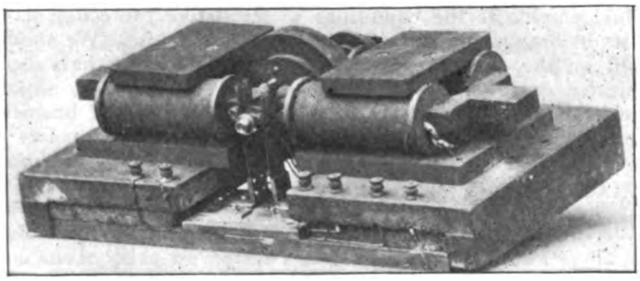
LETTERS TO THE EDITOR

Compound Winding.

My attention has been directed to the following passage which appears in your issue of May 19, 1898, under the heading of "Compound Winding—Patent Void:" "In deciding against the validity of the patent (Edison's) Judge Coxe, as it were, affirmed the decision rendered on the same patent in the English courts, where, after fierce litigation, the bill of the plaintiff was dismissed. In both these celebrated cases the Brush 'teaser' patent was held to be a plain anticipation."

Now, as a matter of fact, the compound winding litigation in England occurred over the respective claims of myself and Brush, to be considered the inventor of compound winding, and three legal decisions declared that Varley's patent, No. 4,905, 1876, was an anticipation of Brush's "teaser" patent, No. 2,003, 1878.

I would mention that almost immediately after the second judgment had been delivered in Edinburgh on appeal (July 16, 1890), and which not only confirmed, but strengthened the judgment which had been previously given, the Anglo-Brush corporation found it necessary to liquidate and to reconstitute themselves as a new company. At the final appeal to the House of Lords, their Lordships delivered judgment on April 5, 1892, and without hearing counsel on the other side they unanimously concurred in the two judgments which had been previously given, and they declared Varley to be the inventor of compound winding.



ORIGINAL COMPOUND WOUND MACHINE.
(Constructed by S. Alfred Varley in August, 1866.)

I enclose you a reprint of the judgment delivered in Edinburgh on July 16, 1890, when the case came before the court on appeal, and also a reprint of the judgment delivered in the House of Lords on April 5, 1892, at the final appeal; and I would call your attention more especially to the judgment delivered at Edinburgh on the occasion of the first appeal (June 16, 1890), certain passages of which I have marked.

I also enclose a reprint of a published letter returning thanks for the testimonial given me as a recognition of what I had accomplished in connection with applied science. I forward it simply because it contains a brief history of my intervention on behalf of the electrical industry in the matter of the compound

winding litigation, and which resulted in liberating the trade from having to pay royalties to the Anglo-Brush corporation.

Perhaps I may be allowed to mention that I had no pecuniary interests to serve when I intervened in the compound winding lawsuits on behalf of the industry as a whole, and that my professional services were rendered largely gratuitously.

Trusting to your courtesy and love of fair play to allow this communication to appear in your next issue, I am, sir, yours obediently, S. ALFRED VARLEY.

17 Lynton Road, Crouch End, London, N., June, 1898.

Abstracts of Discussion on Mr. Alexander Dow's Paper on "Public Lighting in Relation to Public Ownership and Operation."[1]

BY H. M. ATKINSON.

I TAKE that it is not the purpose here to discuss specific cases or grievances. Such an association as this should adopt a platform enunciating its principles on this question, which by its conservatism, temperate tone, fairness and broadness, will appeal to the taxpayer and intelligent voter. This platform should be carefully prepared, should avoid anything aggressive in its tone, or calculated to excite the opposition of advocates of the policy. We should state that we are opposed to municipal ownership on principle, not alone as owners of electric lighting companies, but as taxpayers ourselves. We should state that we are not engaged in a partisan fight, and that whenever one of our members is attacked, he is of necessity right, and must be protected, but that circumstances will solely govern the position we take in each case. We should state that after long experience and earnest study, we, as honest business men, believe that private corporate service under proper legislative control, is far better than municipal ownership. We must distinctly state that we will not uphold our members unless they are honestly endeavoring to give the best service at the very lowest living prices taking into consideration local conditions. We must show that private ownership under proper control means all the advantages of public ownership without any of the risks. We should emphasize the conditions of legislative protection as it exists in France and this country in Massachusetts. We should dwell on the depreciation and losses to which we have been subjected during the past ten years and still are. We should counteract the prevailing idea of great profit in the business. We should condemn at the start high prices and the policy of those who exact them, putting ourselves on record that as street-lighting contracts cover long hours and much consumption, that they should be treated accordingly.

We should adopt a standard system of accounts for ourselves and advocate the adoption of such a system by every municipality—one that will appeal to all business men, interested or not. We should endeavor to show that cities adopting this policy are providing the soil upon which rings and corruption exist, and without which they cannot. We should counsel fair and accurate expressions of facts and figures on both sides, emphasizing the injustice done by careless, inaccurate, unstudied statements. We should urge more complete and adequate methods of bookkeeping in all municipalities. We should drive home in the minds of the people that a city's only source of income is through taxation or bond issues, which means taxation perpetuated; that every dollar raised by the former method is costing them interest as much as the latter. We must urge that cities count cost as fully as private persons. Our fight, in short, is the fight for good and honest government. We must stand fairly on the platform that we, as taxpayers, as well as owners of electric light works, are opposed to the policy of municipal ownership and operation, as our experience has shown us what it is. We must show how legislative control, requirements and penalties create a degree of responsibility which never exists as regards a municipal corporation; how elimination of the factor of self-interest is an effective barrier to economy in production or operation on the part of a municipal corporation, and always will be; that private enterprise will always outstrip municipal ownership in filling the gap between supply and demand; that under contract cost is limited to the price, and under municipal cost is not limited. We should point out the difficulty of ever getting true statements of cost if this policy is inaugurated, as advocates of it will not willingly issue statements condemnatory of themselves, and politicians will not take action that will decrease their patronage. It should be pointed out to taxpayers and voters that municipal ownership of electric light plants will only be a stepping-stone to ownership of numerous other industries, for if ownership of one is advisable why not all?

We should educate public opinion to the unfairness of municipal competition with capital, invited and encouraged to occupy the field, when an industry is an experiment, as long as such capital furnishes good service at a fair price, and that such competition is equivalent to condemnation and confiscation of property without compensation.

BY SAMUEL SCOVIL.

Each of us, I think, will agree with the statement that Mr. Dow makes in closing his able paper—that there is immediate need for clear thinking and for well-considered speech and action in reference to the attitude being assumed by the public towards those corporations performing so-called public services.

In regard to public lighting only, Mr. Dow advocates a declaration of principles by the Association and a recommendation by it to its members of a policy based on those principles. If his suggestion be acted upon, the Association must be careful that the principles which it enunciates and the recommendations accompanying them shall be such that wherever they may be fully accepted and adopted they will result in reasonable prices being offered to the municipality and a fair return to the company upon its invested capital.

I use the words "invested capital" advisedly, for I take decided exception to the principle laid down by Mr. Dow that the present value only of a lighting plant is the proper basis upon which to adjust a price for public lighting. The growth of the electric lighting industry has been almost unexampled in rapidity, and as a natural sequence much of the apparatus originally installed in the average lighting plant has been replaced not once but several times because it had been obsolete. This was no ordinary depreciation such as might properly have been anticipated. It was extraordinary in its character and in degree. For reasons well understood by you, it was impossible for the managers of these plants to secure a price for the service rendered by them which would allow them to cover this depreciation, even could they have anticipated it. As a case in point, I will state that I am informed that there is not in use to-day in the lighting plant owned by the city of Chicago one single piece of the electrical apparatus placed in when the plant commenced operation. It was the necessity of buying new equipment and charging its cost to operating expenses that made the cost of operating street arc lamps by the municipal plant of Chicago for labor and material only $96.40 per lamp per year. You will find these figures given as the cost on page 35 of the Mayor's message for 1896.

Aside from this fact, the original investors in electric lighting apparatus had to pay for patent rights, and these constituted a no inconsiderable part of the aggregate amount of capital which they had to put into the business.

Suppose, for example, the municipality had issued bonds for the total expenditure on its plant, and these bonds, as would probably be the case, were all now outstanding, no one would deny that the interest on such bonds would necessarily be a part of the cost of its public lighting service.

This is in a measure the position which many of the private lighting plants are in to-day. Moreover, it is a fact that it has been the very readiness of the private lighting companies to replace and enlarge their original installations, and of the street car companies to do likewise, that has made possible the great development both as to efficiency and cost of the electrical appliances of to-day. If the municipalities had undertaken the business entirely at the outset, it is not at all unlikely that the development and consequent extraordinary depreciation would not have been anything like as rapid.

As I understand it, the proposition made by Mr. Dow, if accepted by this Association, might well be stated in a resolution, as follows:

"Resolved, That we, the managers of private lighting com-

[1]Printed in the Elec. Engr. June 23, 1898.

panies, in convention assembled, deliberately declare that it is perfectly equitable that part of the capital which we have invested in good faith and with commendable enterprise, be now confiscated by the municipality which we have been serving."

There is one other principle which Mr. Dow asks us to accept, to which I think exception should also be taken. He says: "The only sufficient reason why a municipality should contract with a private company for public lighting is that the private company can do the work, and is willing to do it, cheaper than the municipality can itself do it by direct operation of a public lighting plant."

In my opinion, preference should in every case be given to the private company at the same cost. A contract made with a private company is a known expense. Municipal ownership and operation is an unknown expense. Aside from this fact, however, there is a larger and an all-sufficient reason why private enterprise should be given the preference and individual effort be thereby stimulated.

The question as to whether the municipalities of this country shall own and operate their own lighting plants may seem to be a small matter, except to those whose money is invested in such plants. The axiom that it is the first steps which count is as true of a community as it is of an individual. Once fairly started upon the policy of the municipalization of all public utilities, and who can tell where governmental interference with individual effort will stop. Will it stop with the municipalities? No! All history and experience show that wherever a people have entrusted their liberties to their representatives, to be exercised through a centralized power, these liberties have been lost to them.

The following would seem to be much more acceptable than Mr. Dow's proposition, and be more in accord with American institutions, which is to interfere as little as possible with the individual activities of the citizen:

"The best interests of the public welfare require that a municipality should contract with a private company for its public lighting if the private company can do the work and is willing to do it at a cost not greater than if supplied by a plant owned and operated by the municipality itself."

TELEPHONY AND TELEGRAPHY

The Atlantic Cable Directory and Code.

A FEW months ago The Electrical Engineer published an account in detail of the new book, as above, which has now been issued by the Atlantic Cable Directory and Code Company, of 253 Broadway, New York City. The volume is a massive and handsome one, in a large octavo of nearly 700 pages, bound in brown canvas, stamped in black lettering, and it constitutes an invaluable addition to the mechanism by which international communication is facilitated and international commerce expedited.

"The Atlantic Cable Directory of Registered Addresses and Directory Code" contains a directory of registered cable addresses of the United States and Canada, the names of individuals and firms being arranged alphabetically by States, cities and names, and also classified under the proper business headings. It also contains a telegraph and cable code of about 115,000 code words. The officers of the Atlantic Cable Directory and Code Company, which company is publishing the book, are officials and employees of the Commercial Cable and Postal Telegraph Companies, and this fact in itself is a guaranty of the character of the book. The Commercial Cable Company has guaranteed that 100,000 copies will be printed and circulated, the bulk of them going abroad to be placed in hotels, exchanges, steamship offices, clubs and other public places, as well as in the hands of leading business houses.

The code is so arranged that almost any sum of money in American, English, French, German, Italian, Russian or Spanish currency may be expressed in one word, and one word may also be found to express any quantity, weight or measure in the English or metric system. Phrases descriptive of securities and names of important corporations and active stocks may each be expressed in one word, and phrases for use in shipping are particularly full and complete. Thousands of code words with blanks opposite are scattered through the book, so that the code is especially adapted as a foundation for the preparation of special codes between correspondents.

In the plan and arrangement of the code a radical departure has been made from methods followed by makers of other printed codes heretofore published. Instead of following the old plan of grouping the phrases under subject headings the compiler has first condensed plain English sentences by eliminating the articles and less important parts of the verbs and has then broken them into combinations of words ordinarily in use. The phrases thus formed have been arranged in alphabetical order and may readily be combined into complete sentences. In short, the "Directory Code" is a dictionary of word combinations, although the more useful common sentences and phrases have been included. By the use of the "Directory Code" any ordinary English sentence may be condensed, at least to some extent, and the sentences used in every-day business correspondence may be condensed to a surprising degree.

MARRIED

Johnson—Estell.

Mr. John H. Johnson, of Binghamton, N. Y., was married on June 20 to Miss Florence Estell, daughter of Mr. and Mrs. George Estell, of Kansas City, at the home of the bride's parents, Rev. Dr. H. C. Stanton officiating. The happy pair will reside in Binghamton, N. Y. Mr. Johnson is a well-known engineer in the northern part of this State, having been for several years connected with the F. P. Little Electric Supply and Construction Company. He is now connected with the New York State Electrical Engineering Department.

Osborne—Gale.

We are glad to announce the wedding on June 20 of Mr. W. P. Osborne, of the "National Provisioner," to Miss Emma Catharine, daughter of Mr. W. McClure Gale, of Brooklyn. Mr. Osborne was for a long time the Eastern representative of the "Western Electrician," and his work did much to popularize himself and that journal in this section of the country. A host of friends and admirers extend their congratulations and hearty good wishes.

SOCIETY & CLUB NOTES

An Enjoyable Outing.

The Department of Public Buildings, Lighting and Supplies had their annual outing on Saturday afternoon, June 25. Four tally-ho coaches conveyed the party numbering about 150 from 125th street and Third avenue to Hefter's Hotel, Pelham Bay Park, where an elaborate clam bake was served and enjoyed by all present. During the afternoon, football, baseball, rowing and other games were indulged in until the fierce storm put an end to all outdoor sports. The resources of the company were not however by any means exhausted, as quite a number developed marked musical talent and afforded a fund of amusement for hours. The storm fortunately did not last long, and about 9 o'clock the whole party enjoyed a cool and refreshing drive home, which was particularly delightful after the oppressing heat of the day.

MESSRS. LIEB, VAN VLECK AND WILLIAMS, of the New York Edison Company, have sailed for their European trip of investigation, of which note was made recently in these columns.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued June 21, 1898.

Alarms and Signals:—

ELECTRIC BLOCK SIGNAL SYSTEM FOR RAILWAYS. L. C. Werner, Broad Brook, Conn., 605,941. Filed July 22, 1897. An automatic electric signal system by means of which when a train is about to leave a block, a signal will be transmitted to the engineer in the cab if the block in advance of him is not clear.

ELECTRIC ALARM SYSTEM. A. Overden, Akron, Ohio, 606,076. Filed Sept. 24. 1897. Consists of an electrical circuit closer, an inclined way comprising a conductor rail having a laterally extending plate, a non-conducting rail secured to the plate, and having conducting portions.

Dynamos and Motors:

ELECTRIC MOTOR. F. E. Briner, St. Louis, Mo., 605,850. Filed Aug. 21, 1897. Embodies an armature comprising an elongated core, and induced current-conducting bars whose ends are bent one upon the other, the ends interlocking with each other.

MEANS FOR COMPENSATING FOR TEMPERATURE RESISTANCE CHANGES. C. F. Scott, Pittsburg, Pa., 606,033. Filed Jan. 21, 1895. Combines a movable armature with shunt and series connected circuits in inductive relation thereto, and non-inductive resistances of different values in the respective shunt-circuits and one of which has a different temperature-resistance coefficient from the other.

ALTERNATING CURRENT ELECTRIC MOTOR. R. H. Hassler, Pittsburg, Pa., 606,056. Filed Sept. 6, 1895. A method of regulating the speed of rotation of a shaft in alternating current induction motors.

Electro-Metallurgy:—

ELECTROLYTIC PRODUCTION OF AMALGUMS, ETC., E. and G. Andreoli, London, England, 605,835. Filed Sept. 17, 1896. Consists of a cell provided with positive and negative compartments separated by porous diaphragms, the negative compartments having a raised middle portion in the form of a table, vertical spaces between the table and partitions, and mercury covering the table and filling the spaces to form a continuous cathode.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. F. Wright, Newburg, N. Y., 606,108. Filed Oct. 7, 1897. Comprises a casing, carbon magazines mounted on the casing, carbon holder tubes extended from the magazines and converging, carbon-locking plates on the tubes, and means for automatically operating the plates.

ELECTRODE FOR ARC LIGHTS. C. S. Dolley, Philadelphia, Pa., 606,127. Filed Nov. 21, 1896. An electric arc electrode manufactured of calcium carbide.

Measurement:-

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 605,862. Filed May 20, 1897. Embodies a cylindrical armature, a shunt field within the armature, and a series field without the armature comprising separate horseshoe-shaped cores partially embracing the armature, and series coils wound upon the cores.

ELECTRIC METER. T. Duncan, Fort Wayne, Ind., 605,949. Filed June 24, 1897. Provides a cylindrical armature, a series field without the armature, and a shunt field within the armature comprising a cross-shaped core, and shunt coils upon the several poles of the cross-shaped core.

SHUNT FOR ELECTRIC CIRCUITS. O. B. Shallenberger, deceased, M. W. Shallenberger, executrix, Rochester, Pa., 606,171. Filed April 22, 1897. A shunt for measuring instruments designed to maintain a practically fixed proportion between the currents in the branches, notwithstanding considerable variations in the temperature of the surrounding air.

Miscellaneous:—

ELECTRICALLY HEATED CHARGE FOR CARTRIDGES OR SHELLS. L. W. Bates, Chicago, Ill., 605,842. Filed June 30, 1898. Consists in a cartridge containing an agent adapted to be converted into gas or vapor by heat, together with means for producing the necessary heat electrically.

Railways and Appliances:—

ELECTROMAGNET SWITCH RAILWAY. A. Norman, Toronto, Canada, 605,970. Filed July 3, 1897. Sectional conduit system.

ELECTRIC CONTROLLER. M. W. Hanks, Madison, Wis., 606,009. Filed Dec. 17, 1897. Comprises a contact cylinder mounted on a rotatable shaft, a second shaft having actuating means and a disc provided with springs, the springs engaging with a pin extending from an arm on the cylinder shaft.

ELECTRIC BRAKE. E. W. C. Hoffman, Charlottenburg, Germany, 606,167. Filed Dec. 29, 1897. Comprises a dynamo suitably mounted to be driven by the movement of the controlled wheels and an electromagnetic brake appliance connected with the dynamo, a controlling circuit, and an electromagnetic controlling device connected in the circuit adapted to secure the transmission of the current from the dynamo to the brake appliance when the device is actuated.

Regulation:—

CONTROLLING MECHANISM FOR ELECTRIC MOTORS. G. Gibbs, W. S. Johnson and H. Winkenwerder, Milwaukee, Wis., 605,953. Filed May 10, 1897. Details of construction.

ELECTRIC CURRENT CONTROLLER. J. J. Hogan, New Haven, Conn., 606,012. Filed July 15, 1897. Device for reducing and controlling the intensity of an electric current with a view to enabling a current of normally high voltage to be applied to uses in which a low-voltage current is required.

SYSTEM OF ELECTRICAL DISTRIBUTION AND REGULATION. B. G. Lamme, Pittsburg, Pa., 606,015. Filed Feb. 10, 1898. A method of controlling the speed of a rotary transformer whereby it may be maintained substantially constant irrespective of changes in the amount of inductive load on the alternating current circuit.

Switches, Cut-Outs, Etc.:—

ELECTRIC CLOCK-CONTROLLED SWITCH MECHANISM. R. W. Rollins, Hartford, Conn., 605,915. Filed Sept. 27, 1897. Comprises a clock-controlled switch mechanism, combined with an electric circuit, a clock controlling the circuit and embodying three co-operative circuit controllers, two of which are separately adjustable relatively to each other and are connected with one side of the circuit and control, respectively.

THERMAL CIRCUIT CLOSER. L. Emdin and J. A. Dewson, Reading, Pa., 606,004. Filed Nov. 19, 1897. Particularly adapted for use on an auxiliary fire alarm system.

Telephones:—

TELEPHONE TRANSMITTER. F. A. Ray, Boston, Mass., 605,913. Filed Aug. 18, 1897. Of the granular carbon type.

TELEPHONE EXCHANGE SYSTEM. W. W. Dean, St. Louis, Mo., 606,162. Filed Feb. 6, 1897. Party line system.

LEGAL NOTES

The War Revenue Law.

The following items from the new War Revenue Law relate to the telegraph and telephone and are expected to ensure not less than $750,000 for the Government, the telegraph tax being 1 cent per message:

Sec. 18. That on and after the 1st day of July, 1898, no telegraph company or its agent or employee shall transmit to any person any dispatch or message without an adhesive stamp, denoting the tax imposed by this act, being affixed to a copy thereof or having the same stamped thereupon, and in default thereof shall incur a penalty of $10, provided that only one stamp shall be required in each dispatch or message, whether sent through one or more companies; provided that the messages or dispatches of the officers and employees of any telegraph or telephone company concerning the affairs and service of the company and like messages or dispatches of the officials and employees of railroad companies sent over the wires on their respective railroads shall be exempt from this requirement; provided further that messages of officers and employees of the Government on official business shall be exempt from the taxes herein imposed upon telegraphic and telephonic messages.

Telephone Messages.—It shall be the duty of every person, firm or corporation owning or operating any telephone line or lines to make within the first 15 days of each month a sworn statement to the collector of internal revenue in each of their respective districts, stating the number of messages or conversations transmitted over their respective lines during the preceding month for which a charge of 15 cents or more was imposed, and for each of such messages or conversations the said person, firm or corporation shall pay a tax of 1 cent, provided that only one payment of said tax shall be required, notwithstanding the lines of one or more persons, firms or corporations shall be used for the transmission of each of said messages or conversations.

THE STOCK MARKET

Conditions Generally Good.

Perhaps the best indication of the improvement in trade is to be found in the statement of the New York State Factory Inspector, that 40,000 more people were employed this year than last, in factories under his supervision. Bank clearings are large again, also railroad earnings, while the outlook for fall trade is reported excellent. The large number of small subscriptions to the new 3 per cent. war loan is taken to show confidence in the government and widespread approval of its policy.

Operations in the stock market have been rather restricted and narrow, and the tax on sales of stock is debated as a possible check to speculation. During the past week, 64,960 shares of Western Union were sold, rising from 90 to 93¾. Only 3,717 shares of General Electric were sold, up to 38¼. In Boston Bell Telephone was up to 274.

Copper is quoted at 11.75 cents, being a trifle lower. Heavy steel rail, Eastern mill, is quoted at $17.50.

TRADE NOTES & NOVELTIES

Manufacturers and Dealers in Electrical Supplies in Pittsburgh.—Notes from the Field.—IV.

AURORA ARC LAMP MANUFACTURING COMPANY.

An enclosed direct current arc lamp differing in several particulars from those already on the market is being built by this company. It sustains all the claims made for enclosed arc lamps in general, for instance, a steady soft light, free from shadows, sparkless, long life of carbon (150 to 160 hours as against 8 to 12 hours in the open type of lamp), cleanliness, a minimum expense for cleaning and trimming, and high efficiency (it being 15 times greater than incandescent lights per unit.) Besides these claims, it has several new features, while it leads all others in simplicity of construction.

Two styles of lamps are manufactured, one known as the of-

Office Lamp. Factory Lamp, Exposing the Mechanism.
AURORA ARC LAMPS.

fice, the other as the factory type. The former is only 20 inches in height, while the latter is made any length from 25 to 30 inches. The special features include the mechanism employed for adjusting the carbons, which is very simple, not a wheel or spring being employed. The carbon holder consists of a hollow plunger, which forms the armature of a single coil solenoid. This carries near the lower end a split ring or clutch, which supports a pair of joggle joints terminating in a cam clutch which embraces the carbon just below the plunger, and these are reinforced by a contact plate on each side, insuring proper contact with the carbon, whether the clutch is opened or closed. As the arc increases the force of the solenoid is weakened, when the plunger falls till the clutches rest on a plate, which causes them to open, when the carbon slides down into place and is again lifted to a proper adjustment. The carbon is prevented from falling out of the plunger by means of a split thimble, into which the carbon is pressed when it is first inserted. The opening of the tube is too small for the passage of the thimble, but in the tube it slides freely. At its upper extremity the plunger enters a stationary thimble, which acts as a dash-pot, and cushions the motion of the carbon in either direction. The resistance coil is placed in the canopy upon a porcelain cup, having spiral grooves, into which the resistance coil is laid. The switch is also located on the canopy, but may be placed in a wall socket if preferred. A catch is also provided which is designed to hold the upper carbon at its highest point while the trimmer is adjusting the lower carbon. This is a feature peculiar to this lamp. The lower carbon is held in a split brass socket, which is supported by a single side arms from the frame. This socket also holds the inner globe in position, it being provided with an asbestos washer on its lower extremity, which embraces the lower part of the globe, and is clamped in position by a nut on the under side. This socket is also hollow, and is covered with a cap at the lower end, which provides for removing a carbon should it be broken off in the socket. The outer globe is supported by a split ring and two chains which hook over the canopy.

In the factory type of lamp the solenoid is placed to one side of the centre and there is a split horizonal lever provided which is attached to the armature at one end and at the other to a dash-pot; the same lever actuates an arm, having a ring which embraces the plunger (or carbon receptacle). The motion of the ring adjusts the carbon in about the same manner as described for the clutches. The cases are made of Russian iron and are dust-proof. The lamps are furnished to burn singly on 110 and 220-volt circuits, and in series of two on 220-volt circuits. They are also made for 500-volt circuits. When adjusted for 110-volt circuits they consume about 5 amperes of current. The arc consumes from 75 to 80 volts. The insulation employed in the lamps is all of mica and lava. It is interesting to note that light from an enclosed arc lamp is the only electric ray by which colors can be matched.

It is the purpose of the company to bring out very soon an alternating current and a constant current lamp after the same design.

They also make a focusing lamp which embodies the above principles and is used for stereopticon effects and street advertising.

The company have recently moved to the fourth floor of the Standard Building, No. 2, in Virvin Alley, Pittsburgh, and have fitted up their shop with a fine equipment of tools and appliances with a force sufficient to turn out 100 lamps per week. It is proposed to increase the capacity in the near future to 300 lamps per week.

Mr. L. W. Washington is general sales agent and manager.

Shiffler Bridge Company, Pittsburgh.

The name "Bridge Company" suggests only one branch of the business in which this company are engaged. While they build many bridges, by far the largest portion of the output from their extensive works is steel structural work, including plate and truss girders for roof supports in large buildings, such as electric lighting and street railway power stations, car houses and machine shops. This branch of their work takes them into the field of allied electrical industries, and a description of the process of manufacture and of the plant equipment will enable a prospective purchaser to judge whether he is putting his order into the hands of a concern that is able to execute a contract properly and promptly. A run through the works would satisfy the most exacting engineer that these two requirements could be amply met. We find two great buildings of corrugated iron, one 200 feet square and the other 150x60, adjoining the first and opening into it. These are flanked on two sides by extensive yards, in the first of which we find great piles of new material, consisting of plate steel in sheets of various sizes and thickness, I-beams, angle bars and channel bars of almost every size and description. Five large jib cranes, which are nearly all operated by pneumatic power, together with air trolley hoist, serve to unload the material from the cars, pile it, or deliver it to the trucks and trolley hoist within the

building. Here numerous other pneumatic lifts and large traveling cranes pass it to the shears or punches and drills, of which there are several of enormous proportions. It goes on from these to the riveting departments, where portable or trolley pneumatic riveters quickly pin the parts together, till they grow into knees, triangles or long truss girders, whatever the designs may be. The cranes operate with little or no outlay of power on the part of the operators, the large cranes adjusting the positions to suit the riveters and finally depositing the completed work in the storage yard, where it is painted and ready to be placed on board cars by similar appliances, the cars coming directly into the yard and into one side of the erecting shop. The machine shop proper occupies quite a space in the main building and has a large equipment of metal working tools for making the special tools and appliances employed in the work. In the blacksmith department are five forges and several furnaces, in which are heated the rods from which the rivets are made. There is also a large steam hammer and a number of rivet-making machines, which cut perfectly headed rivets from red-hot bars about as fast as one can count A Straight Line engine provides the power for operating the machinery and the air compressors, of which there are two of the Rand type. There is also a small compound engine of the Westinghouse, Jr., type, for running the lighting generator. About 250 men are ordinarily employed. Among the buildings now under contract by this firm is one covering nine acres, which is to be the tinplate plant of the Shenango Valley Steel Company, at New Castle. Pa. This structure will properly consist of three buildings, each 110x1,206 feet. Among the large structures built by this firm for street railway purposes is that of the Woodland avenue car house for the Union Traction Company, of Philadelphia.

The business was organized in 1883 by the present president of the company, J. W. Walker, and was reorganized in 1890 under the present name. The works are located at Forty-eighth street and Allegheny Valley Railway. The office and designing department occupy a separate building at one corner of the shipping yard.

Keystone Telephone Company, of Pittsburgh.

THIS is not only a telephone manufacturing company, but the managers are also engaged in organizing local companies, and are contractors for the building and equipment of local exchanges. This branch of the work is assuming mammoth proportions, and the number of exchanges under contract at the present writing is twenty-four, with a total equipment of 4,350 telephones and switchboards.

The type of instrument manufactured is known as the Keystone, and these are built in twenty-five different styles, including instruments for short and long distance work; telephones for inter-communicating systems and linemen's test sets. They also manufacture switchboards of all sizes, and special claims made for these are simplicity of construction, durability and rapidity of operation. The wiring is of the best grade of rubber-covered wire, while extremely long and positive spring connections of German silver for the operators' keys and for the jacks, are employed. The boards are of ample proportion, those for 100 drops being 17x20 inches. The drop magnets are of peculiar construction and very sensitive. Each is enclosed in a metal tube, and when in position they are about 3 inches long and 1 inch in diameter, with the armature at the back end. This is attached to the short arm of a delicate lever or catch, which extends along the upper side of the case and by a hook holds the drop cap in place. The slightest motion of the armature releases the catch and lets the drop fall. The transmitters are of various forms, depending upon the results required. For short line work, up to 30 miles, the carbon ball type of transmitter is used. With this transmitter one cell of battery only is required. For long-distance work where considerable battery power is required, a revolving transmitter of the Hunning type is employed. This is so arranged that by turning the mouthpiece at intervals the carbon granules are stirred up, and the trouble from packing is avoided. The long-distance arm transmitter telephone No. 11 is the most popular Keystone instrument, and is of the solid back type, similar in construction to that of the American Bell long-distance, fitted with standard generator and receiver, long-distance transmitter, gravity switch and two cells of batteries. These instruments are claimed to be equal, if not superior, to any long-distance telephone in use, being able, as shown by numerous tests, to do the same work that is being done on any long-distance line, working satisfactorily between New York and Chicago. The standard receivers used in these instruments are made of the best compound bar magnets, with hard rubber cases. The magneto bells are constructed with three magnets, which are placed side by side. These are each made from 1x¼ inch bar steel, cut into 16-inch lengths and bent into a horseshoe form. All are nickel-plated, as are also the connecting bars. First-class material is always employed, and the magnets have never been known to deteriorate from use. The induction coils are of different sizes, depending upon the kind of work, and are of unusual length, thus keeping the wire near the core, so that they have unusual power.

This firm make a specialty of an inter-communicating system for use in business houses and manufacturing establishments, so that all the departments may communicate with each other, independent of any exchange, as a switch is provided in each instrument, by means of which any two may be connected. The instruments in this case are sold outright to the purchaser, and over 2,000 have been installed in Pittsburgh.

The company also manufacture and sell an automatic lightning arrester, designed especially for telephone exchanges, and for this they find a large demand. These are placed between the line and switchboard connections. This consists of an arrangement of springs connected with the armature of an electro-magnet, and so placed that should a heavy current, either from lightning or an electric light wire, come into a line it finds an outlet through the ground strip from the line spring, through a thin piece of perforated mica, and in its passage it energizes the magnet, when by the action of the armature a spring is released, throwing open the circuit and grounding all the lines. The switchboard operator can then in a minute cut off the line having the excess of current, when by replacing the spring the system is again in service. This is claimed to be an absolute protection against burn-outs.

The company also make a specialty of building party lines. There is one running out of Pittsburgh 125 miles in length, on which are 24 instruments, all giving good satisfaction.

The shops of the company, with the office in the same building, are located on Old avenue, not far from the courthouse, and occupy a four-story structure 30x120 feet. About 100 men are employed, and the sales are about 75 instruments a day.

The company is backed by local capitalists, and is under the direct management of Mr. J. G. Ihmsen and Bert Hubbell, secretary and treasurer. Mr. Hubbell claims to have inaugurated the first opposition telephone system in this country, having established an independent exchange at McKeesport, near Pittsburgh, at which time the pioneer company had 60 subscribers, for which the charge was $84 per year. The city now has 900 telephones, which are furnished at a cost of from $12 to $30 per year.

American Wheelock Engines.

The American Wheelock Engine Company, of Worcester, Mass., report the following engines ordered, installed or in course of construction: Six 1,500 h. p. engines for the Chicago City Railway Company, with rope drives; 1 600 h. p. single cylinder condensing engine for the Worcester Wire Mill; 1 200 h. p. for Hammond-Reed Company, Worcester; 1 1,000 h. p. for B. B. & R. Knight, Providence; 1 550 h. p. single cylinder and one 550 h. p. cross compound with rope drives, complete, for Syracuse Construction Company; 1 400 h. p. for the Willamette Pulp and Paper Company, Oregon City; 1 300 h. p. and 1 350 h. p. for Pejepscot Paper Company, Brunswick, Me.; 1 750 h. p. direct connected for the New York Heat, Light and Power Company; 3 350 h. p. direct connected for the J. G. White & Co., New York; 2 500 h. p. cross compounds, direct connected, for Potomac Electric Power Company, this being the second order from them, the previous order being 2 750 h. p. direct connected. They have installed at the Grosvenor-Dale, Conn., electric light plant the high pressure side of a cross compound, putting their cylinder and valve gear on Corliss engine bed, replacing Corliss cylinders. This is the second Corliss engine in the plant they have replaced with cylinder and valve gear. They are now building for the Bibb Manufacturing Company, of Macon, Ga., the high pressure side of a 750 h. p. cross compound, the low pressure side to be one of their low pressure cylinders with valve gear, which replaces the Corliss cylinder and valve gear now on.

Recent Telephone Installations of the Sterling Electric Co.

The Eastern Illinois Telephone Company have just completed the installation of the Sterling Electric Company's new standard switchboard at their exchanges in Gilman and Sheldon, Ill. There is already to be seen a marked improvement in the service.

The E. H. Martin Telephone Company, of Webster City, Ia., are rebuilding their entire plant. The overhead wires are carried in 100-wire cables, the cable terminals, the protective devices and the switchboard being of the Bell type, manufactured by the Sterling Electric Company, of Chicago.

The Livingston County Telephone Company, of Pontiac, Ill., have completed their new exchange building. The poles are erected, the wiring now being put up for the removal of their central office. This new office will be complete in every respect, being equipped throughout with the standard apparatus of the Sterling Company.

Secretary Kimmel, of the Southern Illinois Telephone Company, of Mt. Vernon, Ill., states that his troubles are at an end. He now occupies an easy chair in the rear of the room and enjoys life, having just installed complete Sterling apparatus.

Dr. F. A. Winne, of Brockport, N. Y., has one of the most successful and best equipped telephone exchanges in the independent field of Western New York. His theory has been that the best is none too good. The outside construction is fine, the central office equipment is that of the Sterling Company. The exchange opened by June 5 under the most favorable auspices.

The Valley Telephone Company, who are operating in Saginaw, West Saginaw, Bay City, West Bay City and Flint, will probably have all of their exchanges in operation before the first of July. It is said that the engineering work upon these different exchanges of this company is the best that has been displayed in the construction of independent exchanges. The conduit work, the cable work, the pole-line work, the inside wiring and the arrangement of the exchanges themselves being models of workmanship and of perfect arrangement. This company is equipped with the full line of the Sterling Electric Company, including the switchboards, distributing boards, cable terminals, pole-top terminals and protective devices. The exchanges are well worth a visit by prospective builders or telephone users.

CATALOGUES.

Stanley & Patterson.

The eleventh edition of the above firm's catalogue has just been issued, and contains much valuable information about their well-known telephone apparatus, such as long-distance, combination, interior, short-line and desk telephones, long-distance and grain carbon transmitters, telephone switchboards, transformer coils, receivers and magnetos. They also illustrate and give prices of the well-known Ericsson Swedish telephones, as well as batteries, line wires and material. It is a well illustrated and complete catalogue, and can be had on application to Stanley & Patterson, 32-34 Frankfort street, New York.

Kennedy Valve Mfg. Co.

A very handsome catalogue illustrating the extra heavy patent gate valves and cast-iron fittings for high pressure steam work, indicator devices and blow-off valves, has just been issued by the Kennedy Valve Manufacturing Company, 75 John street, New York. The many admirable features of the gate valves manufactured by this company are ably set forth in the descriptive matter and the splendid wood cuts which are found in the circular. There are also shown gate valves for water-works service and other numerous requirements of steam, water, gas, ammonia, acid, oils, etc. The catalogue, which is handsomely bound, can be had on application to the above firm.

Phosphor-Bronze Smelting Co., Ltd.

These well-known manufacturers and sole makers of the "Elephant Brand" phosphor-bronze alloys have just issued a very complete catalogue and price list of their many phosphor-bronze products, such as wire of various shapes, rods, cast bolts, nuts, washers, nails, wire rods, sash chains and pens, as well as bars and bolts of any dimension. The catalogue contains numerous valuable tables of the weight, size and resistance of phosphor-bronze wires. They are also advertising in a separate pamphlet their well-known "Delta" metal, claimed to be the best forging bronze on the market, as strong as steel, and suitable for castings, stampings and forgings. The company will be pleased to furnish any further information of their products.

The Lakon Co.'s Transformers.

A very unique and interesting transformer catalogue has just been issued by the Lakon Company, of Elkhart, Ind., and is entitled "We Don't Do Anything Else." While every one knows that the Lakon Company people don't do anything else but make good and efficient transformers, still every one in whose hands this pamphlet comes will carefully read its pages. It tells about a dog which didn't do anything but smile, but that he did that one thing so well that he became a well-liked brute. So the company acknowledge their own ignorance on a multitude of subjects, but claim that there is one proposition on which you cannot lose them any place along the line, and that is on transformers, for they claim to know all about them from start to finish, and being pioneers on the subject, they say they ought to. The pamphlet, besides some very humorous illustrations, contains cuts of transformers, testimonials from users, and a price list. Still they claim that they don't tell you much, and if you drop them a card they will fairly flood you with information.

The Toledo Consolidated Electric Co.

One of the cleverest bits of central station advertising has just been forwarded to us by Mr. A. A. Atkinson, the contracting agent of the Toledo Consolidated Electric Company and Toledo Electric Company, of Toledo, O. It is a pamphlet entitled "The Evolution of Light," and contains beautiful half-tone illustrations of the various modes of lighting from time immemorial up to the present, associated with appropriate bits of poetry by Mr. Atkinson. It is most ingeniously and artistically prepared, and cannot but appeal to the user of light into whose hands it may come. Accompanying the pamphlet is Mr. Atkinson's card, on the back of which he requests the user of light to drop him a card or to telephone to him, so that he can call and advise with him as to the best light to use.

Ridgely & Johnson Tool Co.

The above company have just issued a very handsome catalogue of their valveless pneumatic tools for riveting, chipping, calking, chipping iron and steel castings, stone-cutting, carving and lettering. They address themselves to all users of pneumatic tools, and show by a large number of half-tone illustrations how their various tools are constructed and used. There are also shown several full-page cuts of buildings in the course of construction in which their large tools are used. The book has a very handsome cover, on which are embossed the words "Pneumatic Hammers" and the names of the Western sales agents, Jos. T. Ryerson & Son, 18 Milwaukee avenue, Chicago, Ill.

The American-Wheelock Engine Co.

One of the handsomest engine catalogues which has recently come to our notice has been issued by the above firm, located at Worcester, Mass., and whose agents are the Cramp-Hoadley Company, Postal Telegraph Building, New York City. This catalogue is of special interest to electrical engineers and central station men, as it contains a detailed description of the latest type of Green-Wheelock engine, with Hill valve gear. Ten principal advantages of this valve gear are enumerated in the catalogue, as well as the numerous medals and awards received by the company at various exhibitions. It contains also a number of illustrations, showing recent installations of the Green-Wheelock engine, as well as a number of high-duty com-

pound engine tests, which are both interesting and satisfactory. The catalogue will be sent to any one upon application.

Chas. P. Willard & Co.

In a very neatly arranged circular is described the well-known Willard water tube marine boiler for steam yachts and launches, which is claimed to be the lightest, safest and most economical boiler for such use. The circular contains several illustrations of the boiler, as well as reasons why the company believe their boiler to be the best. No fire brick is used in its construction, it has a ready separation of steam from water, there can be no accumulation of sediment in the drum, and the furnaces are large enough to burn any kind of fuel. Every foot of pipe in the Willard marine boiler is tested to 600 pounds hydrostatic pressure, and a certificate of the same is sent to the purchaser. The company is located at 15 North Canal street, Chicago, Ill., where all inquiries should be addressed.

De Veau & Co.

A pamphlet announcing their new 1898-99 catalogue and illustrating their various well-known telephone apparatus and supplies has just been issued by DeVeau & Co., 27 Rose street, New York. It contains, besides numerous illustrations of their apparatus, a cut of the exhibition booth of the company, as well as the editorial comments of the press on their factory recently opened.

ADVERTISERS' HINTS

THE KEYSTONE TELEPHONE COMPANY, 565 Old avenue, Pittsburgh, Pa., advertise instruments for long distance lines.

THE EDDY ELECTRIC MANUFACTURING COMPANY, Windsor, Conn., illustrate one of the direct-connected generating sets for lighting, railway and power transmission work.

THE AURORA ARC LAMP MANUFACTURING COMPANY, Pittsburgh, Pa., whose enclosed arc lamp is described on another page of this issue, will be pleased to send their catalogue of their various types of lamps, prices, etc.

THE WESTINGHOUSE ELECTRIC MANUFACTURING COMPANY, Pittsburgh, call attention to the various electric cranes they build, and illustrate their "ad." with one of their installations.

THE GENERAL ELECTRIC COMPANY are advertising lightning arresters, of which they have already sold a great many this season.

THE HOLTZER-CABOT ELECTRIC COMPANY, Boston, Mass., have recently introduced a motor for small power purposes and which fastens on the edge of a shelf or table by means of a clamp. They are making them in sizes of 1-10 to 1-6 h. p. with a speed of 1,200 and 3,000 r. p. m. They are shunt or series wound and are adapted to be placed on 10 to 110-vole circuits.

THE SPRAGUE ELECTRIC COMPANY, 22 Broad street, New York, illustrate different styles of motors of the Lundell design.

NEW ENGLAND NOTES

THE BIBBER-WHITE CO., of Boston, have just bought out the business of the American Electric Company, of Boston, and will manufacture and market the New Era and other gas-light specialties formerly made by the latter company.

THE ELECTRIC GAS LIGHTING CO., of Boston, Mass., have recently built a 260-drop return call annunciator of the Ross style for the Indianapolis District Telegraph Company, to be installed in Hotel English, Indianapolis. This is one of a number of large instruments built by them this spring for hotels in different parts of the country. The company state that their output of annunciators has been exceedingly large the past few months, necessitating running their factory nights to keep up with their orders.

WESTERN NOTES

THE CENTRAL ELECTRIC CO., of Chicago, are pushing to the front a new stype of standard base 6 c. p. lamp. This lamp is made for standard voltages, is 3½ inches long over all and about 2 inches in diameter. It is exceedingly economical of current and will undoubtedly find large use for signs and other purposes where low candle powers are desired.

THE STERLING ELECTRIC COMPANY, of Chicago, Ill., on account of the rapid increase in their business, find it necessary to open a Southwestern office in St. Louis. Mr. H. A. Coit, formerly manager of the Missouri Telephone Company, and one of the best known men in the independent telephone field, will have charge of the Sterling Electric Company's business in that territory, carrying a full line of samples, and taking charge of their Southwestern business from his office, located in the Laclede building.

THE AMERICAN ELECTRIC METER COMPANY

NINTH STREET and MONTGOMERY AVE.,

PHILADELPHIA, PA.

Is now prepared to take orders for early delivery of all sizes of 3 wire constant potential registering meters.

...THIS METER

is calibrated ready for instant use.
requires no knowledge of electricity to erect.
shows the load passing every instant.
is hermetically sealed.
measures correctly with uneven loads.
can be calibrated with a watch in 6 minutes.
requires no lubrication.
is magnetically shielded.
is direct reading, having no multiplier.
does not require one-thousandth of a horse-power.
will operate for years without opening.
has no springs, jewels or frictional errors.
once right is always right.

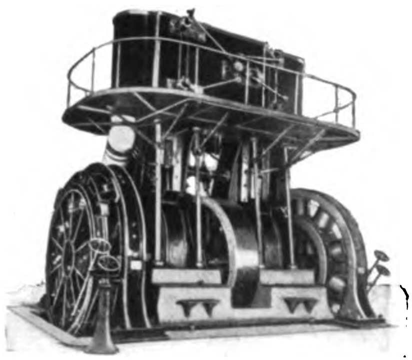
General Electric Company

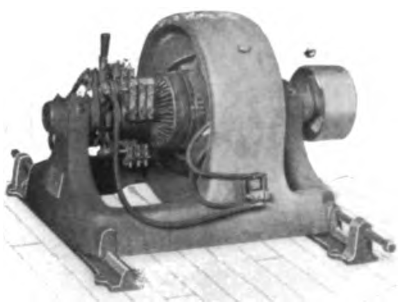
Schenectady, N. Y.

The General Electric Company is the largest electric company in the world, has the most extensive manufacturing facilities, employs the highest electric inventive and engineering talent, builds, as the outcome of years of experience, the standard apparatus of the world. Its guarantee assures the efficiency of its apparatus, and on the basis of efficiency and merit alone it offers its productions.



Direct-Connected Direct-Current Generators.

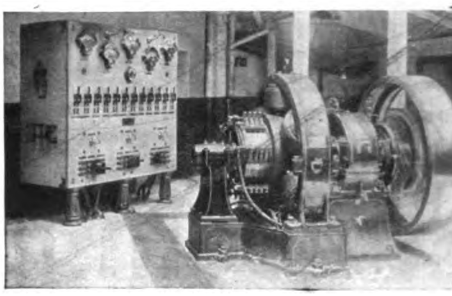
Generators for direct or alternating current, incandescent or arc lighting, for railways, for combined light and power, for power alone and for the long distance transmission of electricity, in fact, for all electrical purposes, are manufactured by it for direct connection to the engine or water wheel, or for belt driving. For direct current work it builds multipolar direct-connected dynamos, and four-pole and two-pole belt-driven slow and moderate speed machines; for alternating single-phase current, the standard alternator; for monocyclic systems, supplying light and power from a single alternator, its monocyclic generators have become widely known and employed; for long distance transmission, its three-phase generators, with stationary or revolving fields, have proved themselves without an equal or superior, and for railway work, its direct current machines, belt-driven or direct-connected, have successfully stood the test of time. It also manufactures generators for electrolytic and other purposes. Each and every generator is perfectly designed, perfectly insulated, perfectly protected and of the highest efficiency.



Slow and Moderate Speed Type Generator.

Monocyclic Generator.

Three-Phase Revolving Field Alternator.



Isolated Plant, Custom House, N. Y. City.

The efficiency of its Air blast **transformers** is such that they are now in use in the principal long distance transmissions in this country. In the new **Type H transformer** new methods of construction render it the most perfect transformer on the market. The core loss is small, the insulation perfect, and the efficiency of the highest. Its use in place of older types has resulted in a marked increase of income at the switchboard.

General Electric Switchboard.

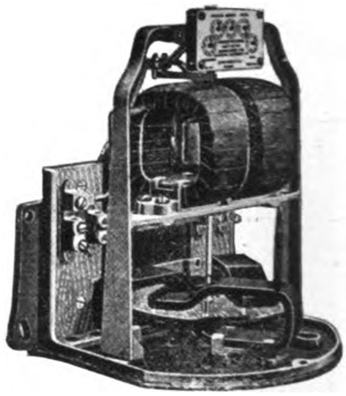
In the design of its **Switchboards** every effort has been made to attain simplicity and compactness without sacrificing any of the features essential to perfect operation. The introduction by it of the panel type **generator and feeder switchboard** allows of uniform increase of the board with any increase in the station. Each device with which each board is equipped has been the subject of the most careful design, and each is a perfect piece of apparatus in itself. The accuracy of the **Thomson Recording Watt Meter** has made it the most widely used meter of the present day. Built for alternating current or direct current lighting circuits, two or three wire, for power circuits, railway circuits, both in the station or on the car, and for storage battery use, they are made in capacities ranging from five to eight thousand amperes.

Air Blast Transformer.

Type H. Transformer.

Recording wattmeters for measuring the total output of any station are also built by the **General Electric Company.**

The **Thomson inclined coil instruments for switchboard, portable and pocket use** devised to supply a demand for trustworthy instruments at reasonable prices, fill every requirement of commercial use. Substantial in construction, with no parts liable to injury or alteration from use, they may be relied upon as accurate. While intended primarily for alternating current measurements, they may be used on direct current circuits where extreme accuracy is not required. The inclined coil instrument has also been adapted for use on series arc circuits.



Thomson Recording Wattmeter.

In **General Electric Rheostats** each unit of resistance is a German silver wire or ribbon wound on an asbestos tube, flattened and creased and then clamped to plates. They are incombustible, completely insulated, almost impossible to injure and easily repaired. The motor starting rheostats are built with automatic switch.

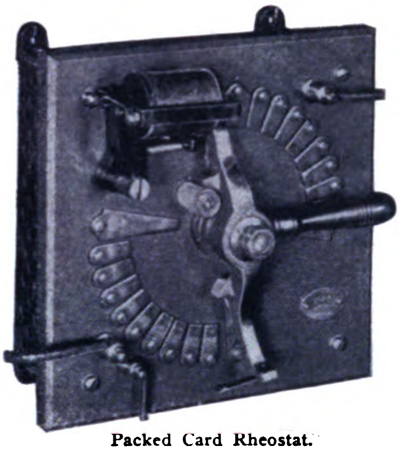
Thomson Inclined Coil Ammeter.

Standard General Electric single-phase and three-phase induction motors, for 60 cycles and 125 cycles, possess a considerably higher power factor than those of any other make, while in efficiency and speed regulation they excel all others. The construction is

Inclined Coil Pocket Ammeter.

unusually substantial and as there are no moving contacts, flashing, sparking or burn-outs are practically impossible.

The **General Electric Company** manufactures **enclosed and open arc lamps** for constant current, constant potential, alternating current, railway and power circuits. Its open series arc lamps have been the standard for years, the other types since the date of their introduction. The economy in carbons, the quality of the light and the safety and simplicity of the mechanism of its enclosed arc lamps for alternating, as well as for direct current service have already established a phenomenal record. For low ceilings its single solenoid enclosed lamp is suitable; for ship and dock use its marine enclosed lamp is now generally used. These lamps are manufactured in a large variety of ornamentation and finish.

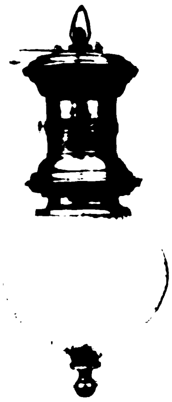


Packed Card Rheostat.

Fifty distinct operations and forty separate tests and inspections are required in the manufacture of the **Edison Incandescent lamp.** The omission of no detail of manufacture and test, the longest experience and the largest production render the Edison lamp the superior of all incandescent lamps. The candle power standard is the highest employed, and no lamp is overrated: both ratings and standards are reliable. Its processes embody all the improvements that careful judgment and long experience show are necessary to the manufacture of a finished lamp of highest quality. The **Edison lamp is absolutely unequalled — the standard of the World.**

Induction Motor.

Electric lighting, railway and power supplies of all kinds—sockets, switches—snap, knife and quick break,—fuses and fuse-holders, cut-outs, both link and plug, automatic circuit breakers, lightning arresters, insulators, railway frogs, crossings, etc., are manufactured by the **General Electric Company,** each device carefully designed for the work to be done. It manufactures its own porcelain, and its own insulation, and guarantees their perfection. It manufactures also **wires** and **cables** for all purposes—aerien, subterranean or submarine.

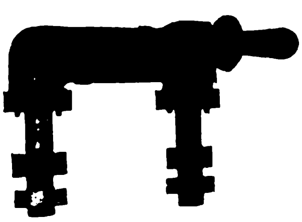


Alternating Current Enclosed Arc Lamp.

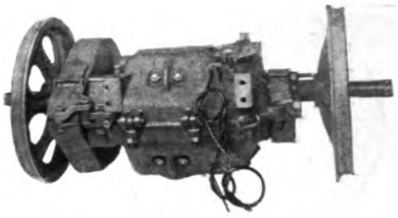
The **General Electric Company** manufactures complete electrical equipments, not only for the largest central stations, but, also, for isolated plants however small. It manufactures complete equipments for light and power plants for council-halls, hotels, theatres, apartment houses, office buildings, etc., as well as for men-of-war, steamships, yachts, docks and wharves. Its marine wiring appliances have been developed to meet the most stringent naval requirements, and the outcome of years of experiment has resulted in the production of electric searchlights equal to any from the best European workshops.

Edison Incandescent Lamp.

The **General Electric Company** first constructed commercially practical electrical machinery for operation in both coal and metal mines, each device specially designed to suit the special conditions prevailing in mine work. Electric locomotives, hoists, pumps, ventilators, etc., of its manufacture are now satisfactorily and economically working



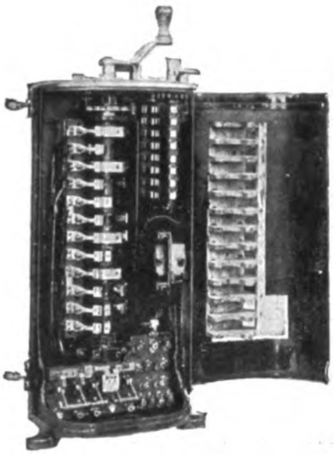
Quick Break Switch.



G. E. 52-Motor on Axle.

in almost every mining centre in the United States, as well as in many foreign countries.

Devoting its attention to the Long Distance Transmission of Power by Electricity, the **General Electric Company** has done more than any other to render the waste powers of nature available to human use. The longest commercial transmission at the highest voltage yet employed has been carried out by it, and not less than one hundred thousand horse-power of its apparatus is now in use in purely long distance transmission work. Each special problem, as it has arisen, has been successfully solved, and to-day, in Long Distance Transmission of power by electricity, the apparatus of this company and the systems employed stand without a rival.



K_2 Controller.

Mining Locomotive.

General Electric Railway motors and controllers are the standard by which all other makes are measured. The pioneer in the electric traction industry, the **General Electric Company** is still the first and foremost. It manufactures railway motors of all sizes from the small mining locomotive motor to the huge motors on the Baltimore & Ohio electric locomotives. Its long experience in the railway field enables it to undertake the complete equipment of any street, elevated, interurban or steam railroad for electric traction.

The General Electric Company is the only company in the world which itself manufactures every electric device necessary in electric lighting, power, railway, mining or long distance transmission work.

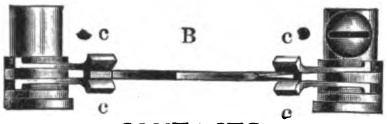
Are You Buying Switches

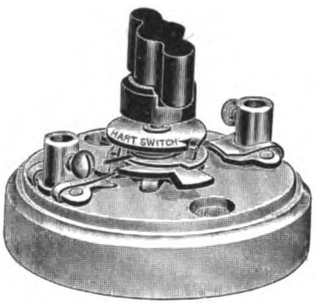


CONTACTS

in these Switches are now this "double-contact" or "Knife Switch" form.

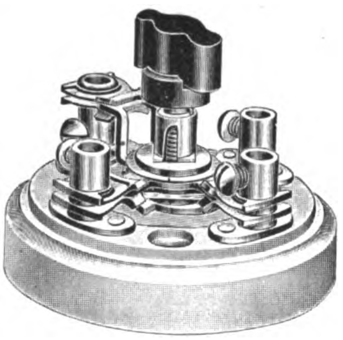
After several years experience it has been found that this is the safest and most durable, and the only one that should be used with currents of more than five amperes.

See our catalogue, page 3.



HART 5 AMP. S. P. SWITCH

See our catalogue, page 4.



HART ELECTROLIER SWITCH

For controlling the lamps on an electrolier in sections.

See our catalogue, page 8.

DIMMER SWITCH

Used when a dim light is required at times.

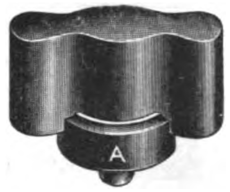
See our catalogue, page 11, for full description and method of wiring.

HART SNAP SWITCHES

Some makes of switches are better than others. No switch is too good for the work required from it. Your circuits must be kept equipped with switches in working order. Whether it is better to buy a good and durable switch in the first place or to buy an inferior switch, simply because first cost is a few cents less, is for you to decide. If you buy inferior switches that do not last, you are simply equipping your circuits with switches on the installment plan—each payment of the installment being almost equal to the full price of a reliable switch.

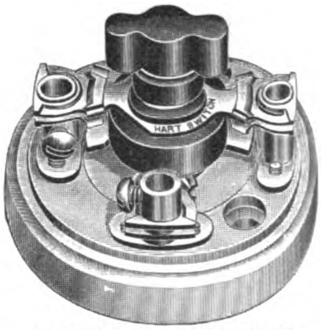
When we say that experience has proved Hart Switches to be the best and cheapest, we do not ask you to accept our statement, but want to call your attention to the matter and lead you to investigate. It is sometimes more satisfactory to investigate beforehand. The following is an instance:

Willie and Johnny set up a lemonade stand.
Willie's sign read:
"Four cents a glass."
Johnny's read:
"Two cents a glass."



HART PATENT SELF-ADJUSTING HANDLE.

The Collar A is pressed downward by a spring, thus holding cover firmly but without friction.
See our catalogue, page 3.



HART 3-WAY SWITCH.

See our Catalogue, Page 25.

A customer came along, bought and drank the two cent lemonade from Johnny, and then decided to investigate reason for difference in prices.

"Why is your's cheaper than your brother's?" he asked. The reply was:

"Cos mine is the lemonade that the puppy fell into."

Hart Switches have been before the public since 1890. Our sales to-day are larger than ever before. Many central stations and leading contractors use our switches exclusively. There must be a reason for this.

Hart Switches are made in large quantities and, therefore, cost of manufacture is reduced as much as possible. Our prices are fair and reasonable.

To guard against imposition on our customers and ourselves, all genuine Hart Switches have the words "Hart Switch" stamped in the metal. Any switch not so stamped was not manufactured by us and is not a Hart Switch.

Our illustrated catalogue, containing 30 pages of interesting and valuable information, wiring diagrams, etc., will be mailed free, on application, to all switch users. Any information regarding switches will be cheerfully furnished.

All leading Supply Houses carry our switches in stock and can fill orders without delay.

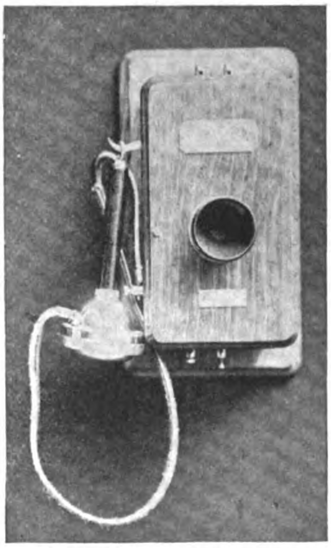
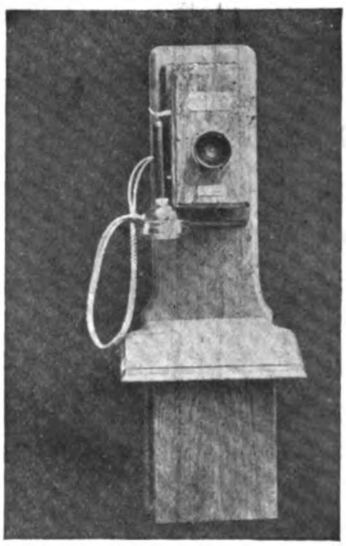
Cosmo, No. 1, $5.00.

"**The Cosmo**" No. 1 will signal and talk as far as any instrument, carbon ball transmitter never requiring adjustment; tone qualities are distinct with lips close to it, or you may stand away 20 feet and the transmitter will still work perfectly. **Particularly adapted to long-distance private line and inter-communicating systems,** but not to ringing bells or working drops.



Cosmo, No. 2, $6.50.

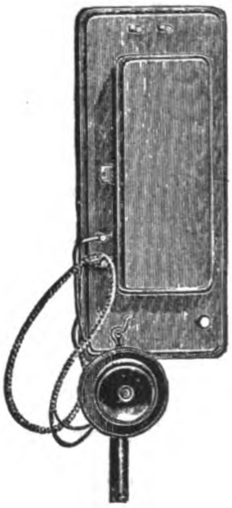
"**Cosmo**" **No. 2** is same as No. 1, except that it is adapted to work drops and ring polarized bells, and is therefore, **a perfect instrument for small exchange use as well as party lines.** In series or in multiple. Has no backboard or battery-box attached, batteries being placed on floor or adjoining closet or shelf.



Cosmo, No. 3, $7.00.

"**Cosmo**" **No. 3** is our regular **Exchange 'Phone;** backboard and batteries attached; complete in itself; it will ring bells, work drops, and in fact do anything required of it.

We make either "Cosmo" No. 2 or "Cosmo" No. 3 with a harmonic signal instead of the bells, also adapted to work drops and for use in Exchange systems, and another form to ring bells and work drops without a harmonic system.



Harmonic, No. 1, $2.50.

"**Harmonic**" **No. 1** has a magneto adapted to be used as a transmitter or receiver; will talk and signal from 50 to 100 miles on a double copper circuit; has our new signal device. When desired we can attach an independent transmitter to it, which increases the price to $4 each.

A NEW INVENTION IN

TELEPHONES

Write For Particulars.

The most serviceable, the most durable and the best telephones now in the market. New method of signaling, which eliminates the dynamo, reduces the cost of our telephones to one-half of that of other companies. With this new method we use harmonic signals, or when desired, polarized ringer and bells. This company owns and controls all patents covering this new and improved system of telephoning. We solicit correspondence with all parties contemplating the use of a telephone, either for exchange or private lines.

THE ECO MAGNETO

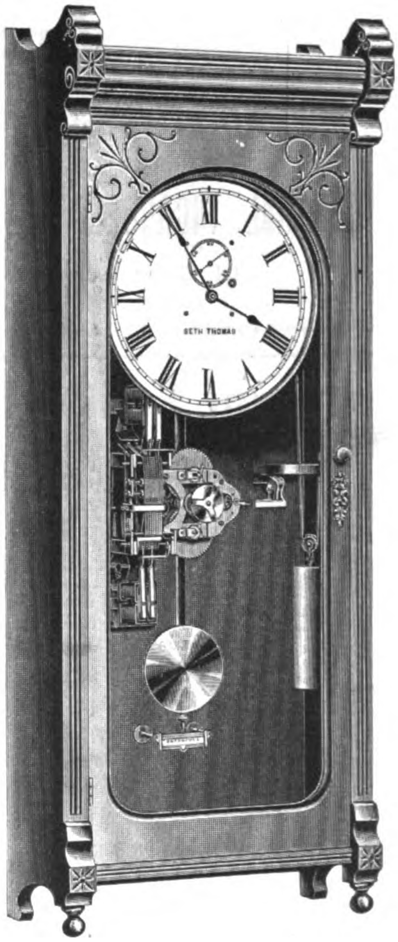
WATCHMAN'S CLOCK.

OPERATED WITHOUT ELECTRIC BATTERIES.

SOME FACTS

ABOUT THE ECO MAGNETO CLOCK:

1. It keeps an exact record of the times when the watchman visits each station.
2. **It dispenses entirely with a battery.**
8. It is simple in construction, and not liable to get out of order.
4. **It cannot be tampered with nor false records be made on it.**
5. It can be sent to any part of the country, and set up by anyone of ordinary intelligence.
6. **It is cheaper** than any other electric watch clock.
7. Every officer and agent of all insurance companies, and every practical person who has ever examined this clock, invariably approves and endorses it over all others.



SEND FOR CATALOGUE.

IN WRITING PLEASE MENTION THIS PAPER.

CAUTION.

THE ECO MAGNETO CLOCK COMPANY ***owns the Letters Patent granted to Geo. B. Fessenden May 1, 1888, No. 381,992 & 381,993.***

An Electric Watchman's Clock operated by a Magneto Generator at each station, each independent of the other, infringes the right secured to this Company by the above patents, and renders each individual user of Magneto Watch Clocks not furnished or licensed by this Company, responsible for such unlawful use, and liable to suit therefor.

...THE...

Roney Mechanical Stoker.

Ten years of constant use under the most varied and trying conditions has demonstrated that **THE RONEY MECHANICAL STOKER**, by supplying conditions most favorable to combustion, renders it practicable

To burn with equal facility both anthracite and bituminous coal.
To burn bituminous and semi-bituminous coals without smoke.
To burn not only the best but also the cheapest fuels, and
To do this without throwing away the resulting heat by frequent opening of fire doors.

CONSEQUENTLY

It does this more efficiently and at less expense than is possible with hand firing, and
Gives more uniform results and does better work at less cost.

THE WIRE THAT WEARS.

We have all seen weatherproof wire lines where the insulation was hanging from the wire in shreds like festoons of Florida moss. It is easy after the trouble has come to tell what caused it and how it could have been avoided. The cause was the use of "no name" weatherproof wire—not any wire in particular, but just so-called "weatherproof" wire. The remedy is the use of genuine "O. K." weatherproof wire purchased direct from the exclusive authorized agents of the "O. K." company. You then get a wire that is known and guaranteed. It is always the same and has been for ten years.

IT COSTS NO MORE.

ELECTRIC RAILWAYS.

MARINE CITY, MICH.—Plans for a new interurban electric road are now being made by Port Huron and Marine City capitalists. The road, as planned, will cover the 20 miles between Marine City and Chesterfield Junction. By means of the Detroit, Ypsilanti & Ann Arbor road, and the Mt. Clements line, a run can be then made from Ann Arbor to Marine City, also from Toledo to Marine City over the Ohio & Michigan Company's track, now under consideration.

WAYNE, MICH.—At a meeting of the Wayne village council a franchise was granted to the Detroit, Ypsilanti & Ann Arbor Electric Railroad Co., for a period of thirty years. The franchise is much the same as others that have been granted to the company. It calls for a 25-cent fare to Detroit, with 40 cents for the round trip. It was agreed to have the line completed before June 1, 1898.

WANTED.

By technical graduate of middle age, a position where practical knowledge of present electrical railroad work and undoubted trustworthiness will secure permanence. Permanence more important than salary; best references. Address,

PERMANENT,
Care Electrical Engineer.
120 Liberty St. New York.

TELEGRAPH.

ST. LOUIS, MO.—Articles of incorporation have been filed by the National Telegraph and Messenger Co. The capital stock is $3,000, divided into 200 shares of $10 each. William R. Knox and Pobion Wight have two shares each. The remainder of the stock is held by J. F. Carr. The business given is that of a telegraph and messenger company.

VICTOR TURBINE WATER WHEEL

UPRIGHT OR HORIZONTAL.

The attention of ELECTRIC COMPANIES is called to this CELEBRATED WATER WHEEL as particularly adapted to their use, on account of its remarkably steady Motion, high Speed and great Efficiency, and large Capacity, for its diameter, being double the Power of most wheels of same diameter. It is used by a number of the leading electric companies with great satisfaction. In the economical use of water it is without an equal, producing the highest per cent. of useful effect guaranteed.

The International Correspondence Schools, B. 978, Scranton, Pa.

ANGLE PLATE USED WITH PLASTIC RAIL BOND AFTER TWO YEARS' SERVICE.

Extracts from paper read before Electrical Section of the Franklin Institute, by Walter E. Harrington, General Manager Camden and Suburban Railway.

"The use of the Edison-Brown Amalgam to improve the contacts of copper bonds showed some very interesting results.

"Used with the Crown bond manufactured by the Washburn & Moen Company, it showed a decrease of 24 per cent. in the resistance by amalgamation."***

"The resistance of such a bond (the Bryan bond) without the Edison-Brown alloy is *very high;* comparing it with two Crown bonds non-amalgamated shows a resistance 146 per cent. higher, but the AMALGAMATION MAKES A REMARKABLE DIFFERENCE.

"Comparing it with the non-amalgamated Crown bond makes a difference of just 42 per cent. in favor of the Bryan (when amalgamated), whereas with two Crown bonds, amalgamated, makes a lesser difference of 23 per cent. in favor of the Bryan bond amalgamated, with a still further advantage of permanency."

"The great objection to the Crown and Columbia, etc., type of bonds consists chiefly in the mechanical defects inherent in them. The vibration of the rail, with the play of the rail joint, results in a continual stress upon the small area of the contact, followed by the final loosening of the bond.

"The writer has removed bonds of the above types which had been in service only a couple of years, that had become loose and the continual movement had worn the bond approximately ⅛ inch smaller in diameter in places.

"The Bryan bond and those types which are flexible, and particularly the Edison-Brown type, are free from such mechanical defects.

"While it was not the purpose of the writer to make tests herein outlined to demonstrate the virtues of the Edison-Brown Bond, still the results were so pronounced that especial stress is laid upon them particularly SINCE PRACTICAL EXPERIENCE HAS DEMONSTRATED THEIR PERMANENCY. It will be noticed that the 'Plastic Cork' type of the Edison-Brown Bond gave the lowest resistance of any of the bonds tested.

"Conclusions.—THE EDISON-BROWN PLASTIC BOND IS THE BEST."

TABULATION OF MR. HARRINGTON'S TESTS.

· TESTS MADE ON PENNA. STEEL CO. 7 INCH GIRDER RAIL, NO. 238. (A=Resistance of Bond. B=Resistance of Joint only).

We are running factory on full time this winter on foreign orders, and have let contracts for new buildings to double our output. But, as demand has more than doubled, orders for Plastic Bonds should be placed as far in advance as possible. The use of our alloys on Power House contacts makes a large reduction of running expenses.

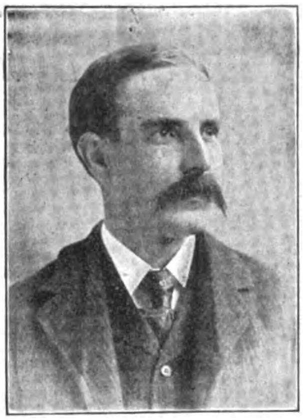
DIAMOND ELECTRIC CO.,

OFFICE: 1202 FISHER BUILDING,

PROF. EDWIN J. HOUSTON is a teacher of undisputed ability. He is even more than a teacher, because the pages he has inscribed teach their lesson directly and effectively. There are many that write, but few of those that write, truly teach and impart the spirit and subject matter of the work in a way that inspires the reader to further efforts. Prof. Houston is a man of the calibre who teaches from his writings. For many years his reputation has been so widespread that to merely mention his name in connection with any scientific achievement was to make the same worthy of respect and consideration. He is a fluent, simple and effective writer.



DR. ARTHUR E. KENNELLY is an electrical engineer of the highest standing. His varied experiences and his keen insight into scientific facts have placed him among the best-known representatives of electrical progress. For more than twenty years he has devoted himself persistently to the electrical science. A great deal of laboratory information, many important electrical laws, and certain rapid and effective methods were discovered by him.

PROF. SILVANUS P. THOMPSON is regarded by all critics as the greatest writer on electro-technics known to electrical engineers. His remarkable genius in this direction manifested itself many years ago, when the science of electricity was just budding and little known that was not arbitrary, empirical, and, in many respects, useless, as a means of further progress. There were many threads to be gathered up, composing the tangled skein of practice, and it required a discerning eye, an analytical mind, and a broadness of comprehension rarely met with, to weave together these broken threads of fragmentary experience and disconnected thought.

The Masterpieces of Electrical Literature

The great progress that has been made in the field of electrical industry, and the fact, that on every side of us new departments of this marvellous science are opening up broad and inviting pathways, make it absolutely necessary for those trying to keep up with the advancement to secure the best possible literature on the subject.

The International Electrical Library meets such requirements and gives to its readers facts and figures, descriptions and devices, which cover the whole range of electrical literature. Its volumes comprise a treatment of the most advanced subjects of the hour, even the design and construction of polyphase machinery.

Any one engaged in any department of mechanical engineering should own a complete set of the INTERNATIONAL ELECTRICAL LIBRARY, because in these days Electricity is prevading mechanical engineering so rapidly that the two arts will be welded indistinguishably in a few years.

The volumes contained in the INTERNATIONAL ELECTRICAL LIBRARY number six.

The International Electrical Library.

The Encyclopædic Electrical Dictionary of words, terms, and phrases, by Edwin J. Houston, Ph.D., is a magnificent work in itself. It fills two large quarto volumes and is a ready reference work that represents the outcome of great labor and research. It contains over 11,000 words and 15,000 definitions, and is the standard electrical reference work the world over. Its distinguished author is well known to electricians of both hemispheres.

Recent Types of Dynamo-Electric Machinery, a complete guide for the electrical engineer, student, and professor, written by Edwin J. Houston, Ph.D., and Arthur E. Kennelly, Sc.D., is the most unique book of its kind in existence, there being no known volume that treats, from cover to cover, only of American Dynamo-Electric Machinery. It is a book which gives proper prominence to the efforts of American engineers, and describes and illustrates in every detail the most recent types of Dynamos, motors, transformers, etc. Messrs. Houston and Kennelly, acting as joint authors in the production of this valuable volume, have given to the profession a book for which it shall ever be grateful.

Dynamo-Electric Machinery, in threeparts, by Professor Silvanus P. Thompson, the first volume treating of Polyphase-Electric Currents and Alternating Current Motors, the second and third parts mainly of generators and motors, represent in total a work widely known among the electrical engineers of the world. These three volumes present the subject of electrical engineering from alpha to omega, and, in combination with the "Encyclopædic Electrical Dictionary" and the volume on "Recent Types of Dynamo-Electric Machinery" cömpose a library of untold benefit to its possessor.

SEE NEXT PAGE.

The INTERNATIONAL ELECTRICAL LIBRARY

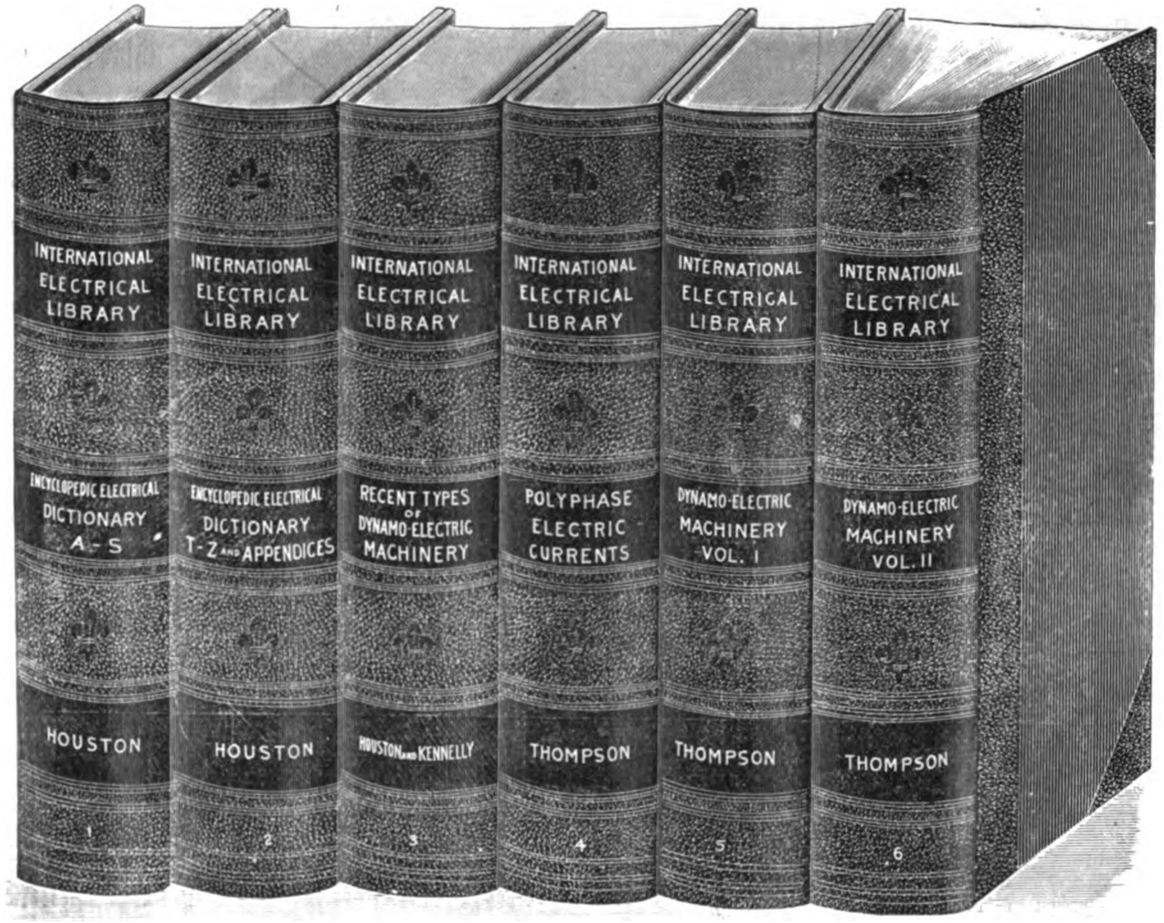
is published in a style in keeping with the high merit of the work. No expense has been spared in the paper, printing, binding and illustrations, to make the set the best scientific library published.

NOW THE QUESTION IS JUST THIS

Has your ambition in life been gratified?

Are you one who knows it all and have nothing more to learn? There are some men, but mostly boys, who think they do.

We take it that you have ambition and, like Lord Kelvin, the eminent scientist, you will always have something to learn to the end of your days.



PAPER. The best quality of paper has been made to order for the International Electrical Library. It is extra super-calendered book half-tone, giving a high surface, which shows the type and illustrations to the best advantage.

PRINTING. The printing on the set has been done on the most improved printing presses, from large clear-faced type and with the greatest care, by skilled workmen. The volumes, with the exception of the Encyclopedic Electrical Dictionary, are printed in two colors.

ENGRAVINGS. Nearly 2,000 fine wood cuts, diagram and half-tone engravings appear in the set, and are shown to the best possible advantage by being printed in extra half-tone dark green ink, the text being in black.

BINDING. The sumptuous half-morocco leather binding has been selected for the International Electrical Library. Full leather backs and corners, cloth sides and gold lettering. Marble lining and silk headbands. This binding is the most durable for repeated reference, and at the same time gives a very handsome and rich effect for library purposes.

SIZE. The six volumes of the International Electrical Library contain nearly 3,000 pages with 25 folding plates additional. Each volume is 9¾x ¾ inches and 2 inches thick. The set weighs 24 lbs. boxed.

Perhaps you may be a steam engineer, an electrical worker, or a foreman over men. Is your present position as high as your ambition prompts you to go? Certainly not. Then it is high time that you avail yourself of the knowledge gathered into the six sumptuous volumes of the INTERNATIONAL ELECTRICAL LIBRARY, by Electrical experts of world known ability. The value of this authentic information must be evident to you—it cannot be estimated by dollars and cents. Consider the value of this work from an educational standpoint—a work that was not possible two short years ago, and then the nominal terms of payment at which you can own a complete set of the standard electrical library of the world.

Now what do you owe yourself?

Every proved item of value in your profession should be yours. You owe it to yourself to see that you get it.

It is poor economy to struggle along with the early works on this subject.

The INTERNATIONAL ELECTRICAL LIBRARY gives you the full benefit of the extraordinary and rapid advances of the Science.

> ## FREE COUPON.
>
> On receipt of this coupon the publishers will send on request an expensive book of nearly 100 quarto pages, showing specimen pages and illustrations printed in colors, which will give some idea of the value of the **International Electrical Library,** and why you should be the owner of a set.

Will you continue to do yourself an injustice by neglecting to avail yourself of the unusual privilege offered to you now, and on terms that will not be a burden or tax on your income?

In placing your order for a set you are not buying a luxury, but an absolute necessity—a valuable and dividend-paying set of tools which will work out your ambition.

Special terms of payment sent on request by the publishers.

AMERICAN TECHNICAL BOOK COMPANY, 45 Vesey St., N. Y.

JOHN A. ROEBLING'S SONS CO.,

Soft Bare Copper Wire,

No. 6 Gasolene Torch.

The great success of the time for cheap light to work by.

Will not blow out or smoke in the wind.

We make kerosene oil vapor burners, to fit these torches when wanted.

We recommend gasolene torches for outside work.

The Celebrated Globe Blow Torch.

MADE ENTIRELY OF COPPER AND BRASS.

Extra strong, almost indestructible, **superior** to any torch made for **soldering electric wires**, and other purposes where an **intense heat** is desired.

A well soldered joint is the ideal one. This torch will do it.

WILL STAND ALL WINDS; NEVER BLOWS OUT.

Used by the leading Electric Light and Railway Companies, contractors, etc., throughout the United States and Canada. A trial of our torch will show its merits above others. Price on application.

Globe Gas Light Co., Mfrs. 77 and 79 Union Street, BOSTON, MASS.
